Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

Google

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 28, 1889.

THE ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOLUME III. (NEW SERIES.)

FROM JANUARY 4, 1889, TO JUNE 28, 1889.

LONDON:

Printed and Published for the Proprietors by BIGGS & DEBENHAM, at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1889

Digitized by Google

INDEX TO VOL. III. (New Series.)

A.

Abdank's, Electrical Music Recorder, 137.
Accident, A Fatal, 385.
Accident Insurance and Electrical Engineers, 175, 225.
Acid-proof Material for Batteries, 426.
Acme Electric Works, 110.
Admiralty Voice Tubes, 366.
Africa, West Coast of, New Cables for, 165, 207, 365, 445.
Algeria, Reduction in Telegraph Rates to, 265.
Alhambra Theatre, Lighting of, 55.
Alternate v. Direct Systems, Major Marindin's Report on, Criticised, 450, 452.
Alternate-Current Machinery, G. Kapp, 157.
Alternate-Current Working, W. M. Mordey, 420, 437, 459, 479.
Alternate Motor, Ganz's, 328, 334, 393.
Alternating Currents, Electrolysis by, 337.
Alternating System, Zipernowski and Deri's, 178.
Aluminium Manufacture, 25, 284.
America, South, Reduction of Telegraph Rates to. 225.
American Canals, Utilisation of, 286.
American Electric Light Association (*see under* NATIONAL).
American Engineers' Visit to England, 125, 366, 445, 485.
American Institute of Electrical Engineers, 408.
American Plant, Importation of, 326.
American Patents, Bate v. Hammond, 127, 135.
Andrews, J. D. F., Wiring Buildings, 269.
Anglo-American Brush Company, Meetings, etc., 202, 204, 222.
Anglo-American Brush Company, New Issue of Shares, 347, 365.
Anglo-American Brush Company, the Year's Work, 12.
Anglo-American Telegraph Company, Meetings, etc., 83, 103, 123, 283.
Animal Magnetism and the Phonograph, 266.
Appleton, J., Secondary Batteries, 399, 416.
Arc Lamp Standards, Allen's, 136.
Arc Lamps, the Brockie-Pell, 41.
Arc Lamp, Maquaire's, 330.
Arc Lamps for Photographers, 3, 14.
Arc Lamps, Sale of Thomson-Houston, 105.
Arc Lamps, S. P. Thompson, 187, 212, 236, 259, 276, 505.
Architects' Association Annual Festival, 366.
Architects and Electricity, 22.
Armatures, Ring, R. S. Dobbie, 117.
Armstrong's Locknut, 21.
Army Signalling, Index to Works on, 147.

ARTS, SOCIETY OF, MEETINGS, ETC.—
Forbes, G., Meters, 79, 98, 119, 133.
Preece, W. H., Secondary Batteries, 371, 420.
Prizes Awarded for Engines, 126.
Thompson, S. P., Arc Lamps, 188, 212, 236, 259, 276, 505.
Where Was the Paper, 425.

"As She is Writ," 327.
Atlantic Cable, Proposed New, 2, 246, 465.
Australasian Electric Light Company, Meetings, etc., 106.
Australian Cables, New, 165.
Australian Enterprise, 367.
Austrian Patents, 42.
Automatic Box for Electric Light Supply, 42.
Automatic Electric Box Company, 285.
Automatic Electric Boxes in Edinburgh, 245.
Avenue Theatre, Electric Light at, 156.
Axles, Engine, A Flaw Detector Wanted, 326.
Ayrton, Prof. W. E., Portrait and Biography of, Supplement to Issue of January 25.
Ayrton and Perry, Profs., Meters, 175, 188.

B.

Badt, F. B., Zipernowski-Deri System, 178.
Ball's Dynamo, A Constant Potential from, 226.
Bamboos for Filaments, 385.
Barton, G. P., Bate Refrigerating Case, 135.
Barton, S. E., Electric Light Stations as Fire Risks, 235.
Bate and Gimingham, Electric Light Measurements, 7.
Bate Refrigerating Company v. Hammond, 127, 135.

BATTERIES, PRIMARY—
Bichromate, 466.
Clark's Standard, 262.
Electrolytic Inner Cells, 68.
E M.F. of, Effect of Magnetism on, 41.
Fortin's, 3.
Gassner's, 1.
An Improved Leclanché, 347.
A Miniature, 246.
New Excitant for, 366.
Weymersch's, 426.

BATTERIES, SECONDARY—
Acid-proof Material for, 426.
by J. Appleton, 399, 416.
Composite Containing Cell for, 1.
Faure v. Julien, 348.
Insertion of, in Cars, 226.
Julien's, in America, 185.
Julien-Sellon Patents, 41, 87, 173, 309.
Lugo's, 106.
New Couple, 106.
by W. H. Preece, 371, 420.
Pumpelly's, 227.
v. Series for Traction Purposes, 366.
Sulphate of Soda in, 348.
for Train Lighting, 476.
Welcker's Dry, 146.
Woodward's, 1, 147, 426.

Baudot's Duplex Apparatus in Italy, 41.
Baxter's Motor, 446.
Beattie's Zines and Carbons, 87.
Beaumont's Variable Gearing, 287.
Bell, Electric, Benz's Dome, 337.
Bell's Asbestos Company, Meetings of, etc., 83.
Bells, Electric, for Churches, 125.
Bells and Indicators for the Admiralty, 366.
Bells, Swinton's Magneto, 106, 351.
Bell's Telephone Patent, United Company v. Siemens, 285.
Belts, The Prevention of Slipping, 366.
Bennett, W. B. G., Electric Lighting at Southampton, 367.
Bentley-Knight Motor Truck, 15, 295.
Berlin, An Electrical Laboratory for, 265.
Berlin Electrical Society's Voltmeter Competition, 366.
Berlin Exhibition, 1.
Berlin, A Smash at, 346.
Berly's Directory, Notice of, 86.
Bermuda-Halifax Cable, 246, 406.
Berry's Dome Electric Bell, 337.
Bessemer, Sir Henry, Elected Hon. Member of the Institution of Civil Engineers, 405.
Bidwell, S., Effect of Heat on the Magnetic Susceptibility of Nickel, 343.
Bidwell, S., Effect of Light on Magnetism, 343.
Birmingham Electric Lighting Order, 517.
Birmingham Exhibition, 25, 68, 105, 185, 245, 286, 387, 467, 505.
Blackburn, A., Joins Mather and Platt's Staff, 245.
Blakey, Emmott, and Co., The Year's Work, 31.
Blasting by Steam, 21.
Bleaching Process, The Hermite, 56.
Blow-pipe, Electric, 169.
Board of Trade and Electric Lighting, Letter to London County Council, 253, 254.
Board of Trade Enquiry, 225, 275, 280, 294, 300, 320, 339, 362, 381, 414, 417, 422, 427, 442, 450, 452, 472.
Board of Trade and Licenses, 3, 9, 29, 36, 54.
Board of Trade's New Unit, 85, 97.
Board of Trade and Supply Co.'s, 114.
Boiler Furnaces for Burning Coal Dust, 125.
Bombay Jubilee Technical Institute, 406.
Books Received, 1, 86, 106, 125, 166, 213, 266, 286.
Boys, C. V., Quartz as an Insulator, 343.
Brake, Electric, Trial of, 88, 165.
Bramwell, Sir F., Made a Baronet, 1.
Brazilian Submarine Telegraph Co., Meetings, etc., 224, 243, 364, 463.
Brazilian Submarine Co., Reduction of Tariff, 225.
British Association of Medical Electricians, 368.
British Association (Scientific), Newcastle Meeting, 127, 246, 305.
Brockie-Pell Arc Lamps, 41.
Brooke, Sir W. O.'S., Death of, 41.
Brooks's Underground Conductors, 387.
Brown, H. P., and the Westinghouse Company, 307.
Brown and Westinghouse, An Electric Duel, 42.
Brush Combined Electric Lighting Sets, 145.
Brush's Double Lamp Patents, 445.
Brush Lamps and the Paris Exhibition, 325.
Brushholder, New, 116.
Brussels, Electric Light Syndicate for, 1.
Brussels Exhibition, 125.
Brussels Royal Medical Society, Prizes Offered by, 286.
Buoys, Electric Light, for New York Harbour, 127.
Burglar Alarms, 66.
Burglars, Electric Defence Against, 125.

C.

CABLE—
Faults, Typical, 266.
History, Too Late! 327.
Repairing under Difficulties, 192.
Subsidies, 407.
Testing, A Conundrum for Young Electricians, 385.
Testing and the Human Body, 266.
Testing, Tropical Questions, 205, 255, 271.

CABLES—
and Imperfect Earth, A. E. Kennelly, 150.
New, 2, 165, 207, 225, 245, 246, 325, 365, 385, 406, 445, 465, 505.
Repaired, 165, 185, 265, 505.
Underground, in Germany, 408.

Cabs, Electric, 365.
"Calais-Douvres," The, 326.
Callender's, Limited, Meetings, etc., 326.
Canals, Utilising Water Power of, 286.
Capehart's Stereo Machine, 126.
Carbon, Beattie's, 87.
Carbons, Fluted, 445.
Cardew's Recording Voltmeter, 406.
Cardew's Safety Device for Transformers, 408.
Cars, Electric, The Backing of, 125.
Casings for Wires, 146.
Catalogues, Notices of, 4, 23, 24, 146, 149, 227, 368, 447.
Cecil, Lord S., joins Board of Exchange Telegraph Company, 265.
Celluloid Slide Rules, 326.
Census Taker, Electric, 128, 487.
Central Station Inspection, 486.
Central Stations in Europe, G. Forbes, 199, 240, 252.

Central Stations, K. Hedges, 471.
Central Stations Worked by Underground Mains, 98, 113.
Chamberlain and Hookham's Meter, 133.
Chandeliers Smashed at Berlin, 346.
Channel Cables, Purchase of, 42, 126, 128, 148, 165, 166, 186, 228, 247, 265, 283, 288, 385, 409.
Chatham, Electric Light and Telephone Wires, 306.
Chelmsford, Electrical Communication for Prisoners, 326.
Chelsea, Eleven Years Progress in, 396.
Chemical Society's Faraday Lecture, 305.
Chemical Society, Address by W. Crookes, 247.
China, Extension of Telegraph to, 21, 325.
Chloride of Sodium, Electrolysis of, 73.
Church Bell, An Electrical, 125.
City and Guilds Institute, Annual Report, 348.
City and Guilds Old Students' Association, 266, 346, 399, 405, 416, 425.
City and Guilds Old Students' Journal, 22, 266, 407.
City of London and Southwark Subway Company, Meetings, etc., 104, 129.
City Notes, 19, 40, 64, 83, 103, 123, 144, 164, 184, 204, 224, 244, 264, 283, 304, 324, 344, 364, 383, 404, 424, 444, 463, 483, 504, 520.
Clark's Standard Cell, 262.
Cleland, W., Testing Materials, 298, 311, 331.
Club, An Experimental, 405.
Coal Combination, 266.
Coal Dust Furnaces, 125.
Coast Communication, 128, 265, 426.
Colbere's Microphone, 43.
Columbia (U.S.) School of Electricity, 125.
Combination, The Electric, 435. 454.
Commissioners of Sewers and Electric Lighting, 22, 41, 65, 109, 169, 233, 265, 314, 316
Companies and Competition, 274.
Companies, Electrical, formed in 1888, 105.

Companies' Meetings, Reports, etc.—
- Anglo-American Brush, 202, 204, 222.
- Anglo-American Telegraph, 83, 103, 123, 283.
- Bell's Asbestos, 83.
- Brazilian Submarine Telegraph, 224, 243, 364, 463.
- Callender's, 326.
- City of London and Southwark Subway, 104, 129.
- Consolidated Telephone, 364, 424.
- Crompton and Co., 124.
- Cuba Submarine, 40, 83, 103, 143.
- Direct Spanish Telegraph, 204, 224, 263.
- Direct United States Cable, 64, 83, 103.
- Eastern Telegraph, 83, 102, 184, 244.
- Eastern Extension Telegraph, 64, 264, 283, 303.
- Edmundson's, Limited, 283.
- Electrical Power Storage, 283, 302.
- German Union Telegraph, 83, 103, 123, 503.
- Globe Telegraph, 64, 264.
- Great Northern Telegraph, 344, 364.
- Humboldt Electric Mining, 41, 187, 264.
- India Rubber, etc., 124, 164.
- Indo-European Telegraph, 304, 324, 363.
- Lancashire Telephone, 184, 463, 484.
- London Electric Supply, 164, 184.
- London Platino Brazilian Telegraph, 383.
- London and Provincial Electric Light, 124.
- Maxim-Weston, 39, 423.
- Metropolitan Electric, 39, 103, 184.
- Monte Videan Telegraph, 303.

THE

ELECTRICAL ENGINEER.

No. 1, Vol. 3. LONDON, JAN. 4, 1889. PRICE 3D.

NOTES.

Gassner's Cells.—The Gassner dry cells are being adopted for automatic electric boxes.

New Year's Honours.—Sir Frederick Bramwell has been raised by the Queen to the baronetage.

Industrial Education.—A book by Sir Philip Magnus on "Industrial Education" has just been published.

West Brompton.—The central station of the House-to-House Company at West Brompton is now open.

Telegraph Convention.—The Argentine Republic has just joined the International Telegraph Convention.

Fire at Derby.—On Saturday Messrs Rowbottom and Goodwin, electrical engineers, Derby, were partially burnt out to the extent of £300.

Southwark Subway.—It is stated that the electric motors to be supplied by Siemens Bros. on the Southwark Subway will be of 100 h.p. each.

The Institution of Electrical Engineers.—The first meeting of this institution will be held on the 10th inst. The president, Sir William Thomson, will deliver his inaugural address.

Vienna.—The central station for Vienna, which is being constructed by Messrs. Siemens and Halske, is rapidly approaching completion, and is expected to be ready for work almost immediately.

Mordey Alternator for Sheffield.—Messrs. Tasker's central station at Shefield, which is running with Thomson-Houston arc plant, has now been fitted with a 35,000 watt Mordey alternator for incandescent lighting.

Paris Exposition.—The railway at the Paris Exposition will run from end to end, and will consist of 100 carriages of various types, driven by 15 engines worked variously by steam, compressed air, and electricity.

Brussels.—The formation of a syndicate is announced, consisting of Messrs. Mourlon Frères, E. Gerard, Van Rysselberghe, La Société Electrique, etc., for the establishment of a central light and power station for Brussels.

New Words.—Mr. A. R. Bennett, in the *Telephone*, suggests the word "telephrase" for a telegraphic message. The counsel for the Dolbear telephone, in the United States, has suggested the word "amberism" for static electricity.

Long Distance Telephones.—Two new telephone lines have been run in Switzerland—one from Langenthal to Aaran, and the other from Neuchatel to Berne. A line will shortly be established between Frankfort-on-Main to Hanau.

Koenigsberg.—The town of Koenigsberg, in Germany, is to have a central lighting station, owned and carried on by the municipality. The cost is estimated at a million and a half francs, and it is hoped to commence running in the spring.

Book Received.—We have received a copy of the new book on "The Telepone," by William Henry Preece, F.R.S., and Julius Mayer, Ph.D. (Specialists' series), published this week by Whittaker and Co., 2, White Hart-street, Paternoster-square.

Election Dodges.—According to a paragraph in the *Pall Mall Gazette*, Sir John Pender, in an interview at Glasgow, said that if he were returned he could bring work to the Clyde connected with submarine telegraphy. Is this bribery and corruption ?

Speed of Telegraphing.—To cope with the increase of business between London and Aberdeen and other towns, an improved system has been introduced, which allow the speed of telegraphing to be increased from 300 to 350 words per minute.

Berlin Exhibition.—An exhibition is to be held in Berlin in April and June this year, consisting of every kind of life-saving and accident-preventing apparatus. The arrangements are now fairly complete, and will include some electrical apparatus.

The Woodward Battery.—The Woodward Electrical Company sold last month 16,348 cells of the Detroit storage battery to a traction company—84 cells to be used for each car. The order amounts to 100,000dols. Another very heavy order has also been given.

Tenders for Chelmsford.—Tenders are invited for lighting the town of Chelmsford by (*a*) gas and oil, (*b*) electricity, for a period of one, two, or three years. Tenders by noon, January 17th. Particulars of Mr. Chas. Pertwee, borough engineer, Chelmsford.

The "Times" by Electricity.—Mr. Albert Gray, of New York, says they can now send out 2,000 h.p. from their motor station in that city. If the London *Times* would give them the contract, he would undertake to run their presses by electrical power from New York.

Piccadilly Electric Railway.—A meeting was held on Wednesday at the offices of the Prudential Assurance Company, in which a resolution was carried objecting to the proposed electric railway between Holborn and Piccadilly, and a committee was formed to oppose the scheme.

Composite Containing Cell.—A new material is introduced by the Composite Cell Company, of 35, Broadway, New York, for storage and battery cells. It is used by the Julien and other companies; it is made up of various materials, including asbestos, and is tough, durable, and impervious to acids.

Digitized by Google

Spain.—The town of Valencia is to have a central station for 20,000 lamps, due to the initiation of the Marquis de Campo. The installation will be carried out by Sen. Planas y Flaquer, of Gerone, and will cost an outlay of a couple of million francs. The power will be taken from the River Turia.

New Transatlantic Cable.—It is rumoured that a contract was signed last week between the Government and the International Cable Company, which has its head-quarters at Brussels, for a new Transatlantic cable to be laid to Bermuda and Halifax by way of Portugal and the Azores. We do not believe in such rumours.

Electrolysis of Tumors.—M. Darin, of the Henry Giffard Hospital, Paris, has cured nine cases by electrolysis of cancer, tumor, hydrocele, etc., besides many cases of depilatation, or destruction of hair follicules. These results were obtained with extremely simple apparatus, very easily manipulated, with the use of the Gaiffe chloride of zinc battery.

Madrid.—The Government regulation as to the sudden lighting of all theatres so far does not seem to have resulted in success in all cases. The light in many of the theatres is deficient—probably on the score of economy of outlay—giving a poor light, and breakdowns are not unknown. Last week the popular Zarzuela Theatre began to get dimmer and dimmer, and the audience streamed out, demanding back their money.

A Woodhouse and Rawson Station.—Among the multiplicity of central stations which are being established or proposed in all directions, we hear a whisper that Messrs. Woodhouse and Rawson, Limited, are not to be left in the cold, and are intending to establish a central station of their own. It is a sign of the times that good profit is to be made when well-established businesses are taking up the central station work themselves.

The Julien Cars.—On the Fourth-avenue, New York, the Julien cars now make a run of 36 miles with one charge. The round trip of 12 miles consumes 15 electrical h.p. hours. The cost is 1d. per h.p. hour; this is 1s. 3d. for the trip, 1¼d. per car mile. At 75 miles a day this would be 7s. 10d. per day. These data are taken from the books at the Julien Company's station, and attention is being given to obtain even still greater economy.

As Here.—Ruinous competition in the States has resulted, in many cases, in companies continually taking contracts at prices leaving no profit. An electric trust has been mooted for some time, with no practical effect, so far; but it seems probable a chamber of control may be formed to fix minimum per lamp prices for arc and incandescent plants, and to prevent several companies attempting to exploit towns where a central station is already successfully established.

The Stettic-Telephone.—Mr. James Lowth, of Chicago, according to the New York *Electrical Review*, has perfected a telephone on a new principle. He has been at work on the instrument for some years. It combines transmitter and receiver, and the transmission is obtained, not by vibration of the sounds from the mouth, but by the vibrations of the throat, against which the lower part of the transmitter presses. It is stated that the instrument has worked clearly over a line of 75 miles.

Barnet.—On Boxing Night Mr. Joel started his permanent engine and dynamo at Barnet, and all seems to be going successfully. The people of Barnet have now settled down to satisfaction with a good average light instead of the blaze they expected; and at the Local Board, at the last meeting, on Tuesday, the result of the discussion was that the cheque for last quarter was passed and paid, and satisfaction with the lighting was expressed by the Board. So ends the preliminary fight. Extension has now to begin.

Society of Arts.—On Wednesday, the 23rd inst., a paper will be read at the Society of Arts, by Prof. George Forbes, on "Electric Meters for Central Stations." Papers, for which dates have not yet been fixed, will also be read on the "Manufacture of Aluminium," by Mr. William Anderson; on "Secondary Batteries," by Mr. Preece; on "Automatic Selling Machines," by Mr. J. G. Lorrain; on "Arc Lamps and their Mechanism," by Prof. Sylvanus Thompson; and on the "Use of Spirit as an Agent in Prime Movers," by Mr. A. F. Yarrow.

The Way to Do It.—In the States it is a common occurrence for orders to be received and executed for a central station to be running within a fortnight after receipt of order. What would be thought in England if we announced one week that some town—say Warwick—had ordered a public central lighting plant, and that in the next week's issue we gave full description of the successful start of the station? We need not attempt to be quite so quick as this, but where is the need for all the usual delay and deliberation on the part of our town and municipal authorities?

New Telephonic Journal.—The first number of *The Telephone*, for Jan. 1, 1889, has reached us—a well-printed paper of twenty-four pages, illustrated with numerous small cuts. It contains a round dozen of articles long and short on telephony, besides one or two translations and notes upon general electrical work, and statistics and quotations of telephone companies. It is to be issued fortnightly, price 6d.; publishers, Messrs. W. Clowes and Sons, Charing-cross. We have no doubt that those specially interested in this branch of electrical work will subscribe with satisfaction to the new journal.

Paris Lighting.—At the last meeting of the Municipal Council of Paris the proposals presented by the third commission were adopted with reference to the concessions applied for by the six following companies: Edison, Geraldy-Deprez, Gaston Sencier, Société du Secteur, Compagnie Victor Popp, and La Parisienne Electrique. The council also accepted the resolutions of the commission appointed to settle the contracts for machinery and plant, and accepted the tenders of Belleville et Cie, Weyher et Omhemond, Lecouteux et Garnier, Compagnie Continentale Edison, and M. Patin.

Reunion at Glasgow.—On Friday evening, 28th December, the friends and workmen of Messrs. McWhirter, Ferguson, and Co., Faraday Electrical Works, Glasgow, held their annual reunion in the hall, St. James'-street, when over 50 sat down to a sumptuous repast. The chair was occupied by Mr. Wm. McWhirter. After tea the chairman addressed the meeting on the progress made by the Faraday Electrical Works during the last five years, and especially impressed upon the apprentices the need for constant and diligent study to enable them to command respect in their chosen profession as electrical engineers.

Fishing by Electric Light.—The French fishermen on the coast of Maine now use a small primary battery, with an incandescent lamp, to attract the fish, the whole

Digitized by Google

being dropped overboard and regained when the trip is ended. The old method of leading wires from a source of electricity on board to the lamp often resulted in fouling the nets. The battery consists of six Bunsen cells, in which, however, chromic acid is placed instead of nitric acid, formerly used. The cells are connected in tension with a 12-volt Edison lamp. We shall no doubt soon see a very general adoption of this method of fishing by coast fishermen.

Not the Institute.—We note that the last issue of the *Journal* of the Society bears the new name as adopted in last general meeting as a supplementary title. Attention should be called to the fact that this new title is not the "Institute" of Electrical Engineers; this was a mistake which was easy to fall into at first, and many obtained the idea that such was the new title. This mistake is embodied in an otherwise pretty fancy of a monthly contemporary illustrating the apotheosis of the society. It should be well enough known now, since the publication of the resolutions, that the new title is, "The Institution of Electrical Engineers."

Electric Thermometer.—M. Chaperon has recently devised a galvanic couple sensitive to light for measuring degrees of illumination. A somewhat similar application to measurement of temperatures has been devised by Mr. Bruce Warren, chemist to the India Rubber Company, Silvertown, who has discovered that arachide oil varies in resistance very rapidly with change of temperature. The oil is placed in a test tube in which two wires from a galvanometer are immersed. The combination then acts as a thermometer, and is sensitive enough to indicate minute fractions of a degree. The discovery may possibly have an important practical application.

The Fortin Cell.—The French technical press describe a new battery devised by M. Fortin. It is constructed of rectangular cells, 4in. square by ¾in. deep, placed one above the other. Three small carbon rods project through holes in each cell slightly above the surface. The zinc plate rests on these, and the positive plate of hard carbon rests upon three plugs of indiarubber placed on the zinc plate. M. Fortin states that this battery will run a 10 c.p. lamp for 10 hours at the cost of a few centimes. The solution is made by dissolving 1lb. of bichromate of sodium in one gallon of water, to which 1lb. of commercial sulphuric acid has previously been added.

Lens Globes for Electric Lamps.—Mr. S. Heimann, of New York, has designed globes for arc and incandescent lamps, consisting of a combination of lenses so arranged as to compensate for the irregular radiation of light in different directions and angles from the lamp. These consist for arc lamps of two lenses of a globe made in the form of a cylindrical double convex lens round the side of the globes, by thickening the glass opposite the arc; and in the incandescent of a thickening of the bulb at the sides and bottom so as to render the light stronger in those directions that it is naturally weakest. The idea may be capable of a practical application, and is at least worth consideration.

Light and Power Station in Austria.—An interesting installation for the distribution of light and power has been constructed by Messrs. Siemens and Halske in Weissembach, Austria. A number of houses are lighted, including villas, hotels, restaurants, and two mills, and at the same time power is transmitted from one of the mills to the other, a distance of a quarter of a mile away, using part of the power of a neighbouring waterfall. A Jonval turbine furnishes 20 h.p., which, by means of a countershaft, drives a Siemens dynamo, giving 130 volts and 90 amperes. A cable is run to a motor at the further mill, and leads are run off made along the circuit for the lamps, which are lighted only at night, when the motor is not working.

Price for Motor Service.—The charge for electric motors in New York is ½d. an hour for a sewing machine, 16s. 8d. a week for 1 h.p., 25s. for 2 h.p., and 12s. 6d. a week extra for each additional horse-power. The prices are not absolute, but vary somewhat with certain conditions. The cost generally is less than that of steam; the great advantage is that no great amount of capital is invested, as is the case with steam or gas engine plant. The exact amount of power used is charged for, and it can be turned off as easily as gas or water. A 1 h.p. motor will run three Gordon presses and a cylinder press. An eighth of an horse-power motor drives a fan or sewing machine. The cost of running an ordinary passenger elevator by electrical power is about 33s. a week.

Important Decision of the Board of Trade.—The Board of Trade, by virtue of the powers vested in it by the Electric Lighting Act of 1882, has, we are informed, decided to refuse the whole of the applications that have been made to it to grant licenses for the supply of the electric light to any part of the metropolis. The effect of this decision is that all applications for supplying the electric light to any part of the metropolis will have to be sought by means of provisional orders, which, if granted by the Board of Trade, will have to receive the sanction of Parliament before they can become operative. All provisional orders that may be granted will, therefore, be embodied in a confirmation Bill and referred to a Select Committee, before whom opponents will be heard.—*Daily Papers.*

The Telephone in London.—The messages transmitted along the United Companies' wires on the 17th ult. amounted to 103,428, the highest yet reached for any one day; while the messages for the week ending 18th ult. amounted to summed up 586,294, being at the rate of 30 millions of messages per annum. The United are erecting a main trunk route to the North, and have already built half the trunk that is required to connect London with Birmingham. A main trunk to the West is also being surveyed, and way-leaved with a view of placing Bristol and the South Wales coal-fields in telephonic communication with the metropolis; while a new route to the South is in progress for the benefit of Brighton and the towns on the Southern Coast. As these routes are gradually constructed outlying towns can be joined up to them, and thus establish a complete network of telephonic wires between the provincial towns and London.

Photographic Arc Lamps.—We give elsewhere illustrations of arc lamps adapted for photographers' uses, by Faraday and Son. It will obviously be easy, where central stations are active, for photographers to obtain current for these arcs from the mains. In isolated circumstances this is not possible, and no good battery or generator is at present practically available. Two methods suggest themselves: a small generator, such as an oil or petroleum engine—the Shipman oil engine, Serpollet's instantaneous steam generator (recently described), or a small compact water or gas engine—rotary or other. But possibly some of our inventive geniuses will produce an exaggerated Ruhmkorff coil to commute heavy currents from—say, two large storage cells at heavy

Digitized by Google

discharge for the period of two or three minutes into alternate currents, and transform them up to 40 or 50 volts, and so produce a temporary arc light. This would be exceedingly convenient in many cases for arc lamps, and would save excessive cost for batteries for the necessary voltage.

Albion T. Snell on Electromotors.—The next meeting of the City Guilds Old Students' Association will be held at the Central Institution, Exhibition-road, South Kensington, on Wednesday, January 16, at 7.45 p.m., when what we are sure will be a most interesting paper by Mr. Albion T. Snell (of Messrs. Immisch and Co.), upon "The Design of Electromotors," will be read. The outline of Mr. Albion T. Snell's paper is as follows: The dynamo as a reversible machine; the methods of designing motors; the torque; the armature considered as an independent magnet; the field-magnets; relative power of armature and field-magnets; shape of magnets practically immaterial to the general result, providing sufficient excitation be given; pole-pieces; predetermination of characteristics—insufficiency of present methods; method of examining distribution of magnetic field in dynamos and motors; method of estimating quantitatively the heat waste and frictional losses in a motor by brake tests. The exceptional interest of the paper to electrical engineers will, no doubt, cause a good attendance of visitors, besides a full meeting of members.

Overhead Wires at Birmingham.—The *Birmingham Daily Post* has carefully discussed with an eminent electrician the question of overhead wires, and gives its adherence to the tentative policy of overhead pioneer wires under proper restrictions. After reviewing the reasons for such a policy—the difficulty of laying underground mains, of obtaining consent of the authorities, of judging the demand at various points, and of settling upon the size of main cables for maximum supply—the *Post* concludes as follows: These arguments, so far as they suppport the desirability of allowing a temporary use of overhead wires, seem to be well grounded. Of course all that is said about inconvenience to the electric lighting companies would go for nothing if the danger from overhead wire were as grave and pressing as the alarmists make out; but the evidence does not satisfy us that it is. On the contrary, the risk seems to have been exaggerated, and the public may therefore await with comparative equanimity the probable decision of the committee in favour of the use of overhead wire for purely pioneer and experimental purposes.

Internal Friction of Engines.—Professor Thurston, at the Scranton meeting of the American Society of Engineers, investigated in detail the loss in friction internally in the various parts of steam-engines. The friction of the main shaft is one-half or one-third of the whole loss, and the introduction of a system of oil baths would tend to regain most of this loss. The next item is that of the piston and rod, which varies, and might be considerably reduced. The third item is the loss in friction of the valve in engines having unbalanced valves. In the straight line engine the loss has been brought down from 26 to 2·5 per cent. by skilful balancing of the valve. From the thermo-dynamic point of view the steam-engine is nearly perfect. An ideal engine would consume 10lb. of steam per h.p. hour, and engines have been made to work as low a consumption as 14lb. of steam. It is not impossible, if the internal losses by friction were carefully overcome, that the consumption in a good engine might be reduced to 12lb. of steam per h.p. hour, and most engines could be made to yield 5 or 10 per cent. of energy usefully, now wastefully consumed. Attention to the matters thus pointed out are well worthy the careful consideration of electrical engineers engaged in both private and central station work.

Electrical Action of Dental Fillings.—Dr. George W. Whitefield contributes to the *Western Electrician* an exhaustive and interesting article upon the galvanic action of dissimilar metals used as fillings in hollow teeth. He points out that Dr. J. V. Black has proved that unclean teeth are peopled with microbes (especially in between the teeth), which live on the *debris* left around the teeth; some of these exude lactic acid, which tends to destroy the teeth and gums. Dissimilar metals, Dr. Whitefield argues, when placed in different positions in the mouth set up electrolytic action. Gold is often used in one place and tin, or often a combination of mercury with tin, silver, zinc, and copper in amalgams, in other teeth. These, with the fluids of the mouth as excitants, give small currents of electricity, which often tend to eat away and roughen the surface of the teeth, giving lodgment to Dr. Black's microbes. With gold and tin fillings only, the baser metal becomes coated, and the action practically ceases, but with the amalgams the mercury allows the action to continue. If amalgam must be used, he concludes, use those grades which will readily become coated, as this reduces the galvanic action and protects the plug from the fluids of the mouth. Metallic fillings should be avoided for those teeth which are soft in structure, as the normal plasma exuded from the tubuli will tend to set up electrolytic action. Cement is the only filling that should be used in such cases, and in the course of 18 months or so the tooth will harden and be capable of proper manipulation, to prepare it for the king of fillings—gold. A tooth treated this way will not be sensitive, and the fillings will last.

Edison-Swan Catalogue.—The Edison and Swan United Electric Light Company have forwarded to us their catalogue of incandescent lamps for January, 1889. It is very complete, neatly got up, and arranged for ready reference in paragraphs. Particulars are given of the usual lamps at 48 to 110 volts; special miniature lamps 1 to 5 c.p., and larger lamps at 25, 32, 50, 100, 200, 500, and 1,000 c.p., the last three being for use on incandescent circuits in place of arc lamps, a branch rapidly becoming of greater importance. The Edison and Swan Company are now giving considerable attention to these high-power lamps. With regard to efficiency, all lamps marked at less than ·9 ampere are marked at 4 watts per candle, and above this at 3·5 watts per candle, though special buyers can mark their own efficiencies. The company now make the bulbs of their lamps in two shapes—round and pear-shaped, and these are made in six standard sizes in all. Lamps are made for the following terminal fittings: Bottom loop brass collars, black glass ends, side contacts, central contacts, Edison screws, brass or copper lugs. These various terminals are illustrated, as are also the different shapes of bulbs and the bayonet-joint and side-lug lampholders. Various regulations as to packing, delivery, mounting, lamps obscured, silvered, and varnished in colours and other matters of interest to buyers of lamps are fully given. One point of interest is the detail given of the standard cells employed by the company as devised by Dr. Fleming. The company are prepared to furnish standards of resistance, or legal ohms, and also standard

Digitized by Google

cells for use in calibrating galvanometers. All previous lists are cancelled by this catalogue, which should be on the desks of all electrical engineers.

Grosvenor-place to be Lighted.—At the last meeting of the St. George's Vestry, the lighting of Grosvenor-place publicly with electric light was decided upon. The Electric Lighting Committee recommended that an application from the London Electric Supply Corporation, Limited, to light the area between Hamilton-place and St. George's Hospital, as far down Grosvenor-place as Halkin-street, be granted upon an agreement being entered into embodying the following conditions—viz.: That the corporation bear the whole expense of the laying of wires, etc., for making the experiment, and that a light quite as good as that now given by gas be supplied to the satisfaction of the Vestry, who will pay £300 per annum for the lighting of the area, the agreement to be for a period of twelve months certain, and to continue unless determined by three months' notice on either side; that the corporation reinstate the parish lamps and paving, if removed or interfered with, to their present condition, and that no use of the parish lamps by the corporation shall in any way interfere with their being lighted by gas at any time, if so required; and the details as to the exact system of lighting be left to the corporation. The Electric Lighting Committee recommended "That the Vestry resolve that it is in their opinion to the advantage of this parish, and, so far as the Vestry could see, of the inhabitants of London generally, that joint-stock companies should commence operations for electric lighting under licenses rather than provisional orders." Lord Hobhouse, in moving the adoption of this report, said the company had already wires laid within this area. The expense of lighting the area by gas was about £300, and so they had fixed that sum in the agreement. Mr. Southon seconded the motion, which was agreed to, with a rider prepared by Sir Walter Phillimore, regretting that the Board of Trade had refused to enter into the proposal of granting licenses on a principle which would seem to prevent any licenses in future being granted to them.

The Electric Lighting Act.—In the House of Commons on the 20th ult., in answer to questions by Mr. Watt, the President of the Board of Trade (Sir M. Hicks-Beach) said the Electric Lighting Act, 1882, did not preclude the granting of licenses to one or more persons, firms, or companies to light the same area; that the Board of Trade could not give power to break up streets except under a license or provisional order, and that enquiries as to the ability of undertakers to carry out the work before licenses were granted were made by the Board of Trade. Two licenses have been granted since the last report to Parliament. In reply to the question as to whether the reason of the abandonment of the licenses obtained by companies under the Act of 1882 was the enormous law costs incurred by the opposition of the Local Boards, Sir M. Hicks-Beach said that no such reason as that referred to by the hon. member had, to his knowledge, been assigned for the abandonment of licenses. Mr. Rowntree asked the President of the Board of Trade whether his attention had been called to notices given for supplying electric light in the parish of Kensington, under the Electric Lighting Acts, 1882 and 1888, by the four following companies—viz., the Kensington and Knightsbridge Electric Company, Limited, the Chelsea Electricity Supply Company, Limited, the Notting Hill Electric Lighting Company, Limited, and the House-to-House Electric Supply Company, Limited; whether he was aware that the said companies proposed to conduct their operations mainly, or very largely, within the same area, and in many instances to take power to break up the same streets, roads, or places; whether it was the duty of the Board of Trade, before making any provisional order, to take cognisance, of its own motion, of such *prima facie* objections; and whether the Board would not take any cognisance unless and until it was moved thereto by the local authority, or other parties interested. Sir M. Hicks-Beach: The answer to the first three questions of the hon. member is "Yes"; and the answer to the last is, that it is the duty and practice of the Board of Trade, in framing a provisional order, to consider any objections to which their attention is called, and also any such as may occur to them.

Electric Tramways for Milan.—A commission was recently appointed by the Omnibus Company of Milan to visit and report upon various systems of electric tramways in use in Europe. This commission consisted of Signore Pompeo Moneta, C. Margutly, and B. Cabella, who were requested to give special attention to accumulator systems. The commission, after having examined the principal English and Belgian lines, regretted they had not been able to ascertain that any of the systems worked with storage batteries were at present successful from the financial point of view. At Brussels the Julien system gave satisfaction in working, but was costing 4 centimes per car mile in excess of horse cars; the commission, however, remarked that it was impossible to judge fairly of the expense with a total of only four or five cars running. The gradients also were heavy, varying from 3 to 12 per cent., where the electric cars were in use. The Elieson cars were not running on the Stratford line when the commission visited London, but they had, nevertheless, considered the system. The commission were not in favour of the use of electric locomotives. They had examined all the various accumulators proposed, but the cells of the E.P.S. Company and of Reckenzaun were the only ones that the makers would guarantee a maximum expense of maintenance. Among the systems of gearing, that of Reckenzaun seemed the best worked out and most practical. Signor Moneta recommended particularly the employment of two motors to each car; he considered it advantageous to transmit the power to both axles instead of to only one. He also praised the system of Mr. Reckenzaun, by which the speed or power of the motor could be varied, at the same time saving current from the batteries. This is done by varying the resistance of the coils of the motor by connecting up in different combinations. The report terminates with the consideration of the cost of running with electric traction as applied to the line from Milan to Monza, with eight large cars, carrying 50 passengers. This line, at present run by horses, has a length of 16 kilometres (nearly 10 miles), and although there are no heavy gradients it is impossible to run to the regulation time, which, including stoppages, is fixed at 58 minutes. Signor Moneta calculated the cost of electric traction for the line to be 25 centimes (2½d.) per car mile, inclusive of coal, oil, waste, salaries, etc., depreciation at 12½ per cent. for machinery, and of 30 per cent. for accumulators, and allowing interest on capital at 6½ per cent. The conclusions of this report, says the *Bulletin Internationale de l'Electricité*, from whom we abstract the above, are very favourable to the adoption of electric traction at the line from Milan to Monza, and are of great interest, being, as they are, the result of serious and impartial examination of the principal storage systems proposed in Europe.

LITERATURE.

Dynamo Electric Machinery. By SILVANUS P. THOMPSON, D.Sc., B.A. (Third Edition.) E. and F. N. Spon: London, 1888.

That Prof. Thompson's "Dynamo Electric Machinery" satisfies more or less completely the wants of a somewhat numerous class of readers is shown by the fact that the work has now reached a third edition. In the volume before us a very successful attempt has been made to write the subject up to date, and, considered as a manual for students, there is not perhaps much fault to be found with the book. But between the practical considerations which guide the work of dynamo making as carried on in the factory and the traditions which govern the study in technical colleges there is, apparently, a great gulf fixed—a gulf, moreover, which Prof. Thompson's book has not yet bridged.

In his preface to the third edition, the author remarks that the mathematical portions which appeared in former editions have been curtailed, a fact which is to be regarded as a healthy sign. The men who design dynamos contrive to do with as little mathematics as possible, and, generally speaking, have neither the time nor the inclination to soar in analytical flights. They regard mathematics strictly in the light of a means to an end, and are somewhat prone to look with contempt upon the yards of symbols which it has been the fashion to write in connection with dynamo investigations. The formulæ of the practical man are few and simple, but in his hands they form powerful mental tools which are capable of turning out a vast amount of useful work.

The first chapter of this book is occupied with introductory matter, historical notes, and definitions of electric and magnetic units. The author starts the very first paragraph by defining the dynamo as "a machine for converting energy in the form of mechanical power into energy in the form of electric currents, or, *vice versâ*, by the operation of setting conductors to rotate in a magnetic field, or by varying a magnetic field in the presence of conductors." This definition is certainly comprehensive enough for its place at the beginning of the work. We should have thought that moved to a position at page 35 it would have been more in harmony with a general plan of piecing the dynamo together bit by bit, which seems to be foreshadowed in Chapter II. We cannot say that we agree with the order in which the matter of the book is presented. It seems to us that the abundance of material suffers through absence of system, and that the edition now before us is impaired by the author clinging too closely to the plan of former ones.

After dealing with the Organs of Dynamos, the author considers, in Chapter IV., the Induction of Currents in Armatures and the Distribution of Potentials around the Collector. Prof. Thompson tells us here that in every well designed machine the induction in the sections of the armature can be represented by a curve of sines. This is, we think, an error. As a matter of fact, every designer aims at preventing his induction curve from being a curve of sines, because he well knows that with such a state of things he will have on his collector a neutral *point* instead of the neutral *surface* which he wishes. In all good dynamos there is a number of the armature-coils idle, and made purposely so, that sparking may be avoided. It is only in multipolar disc machines, where the poles are close together, that there is difficulty in getting a neutral surface or any considerable length of armature core through which the lines of force run without diminishing in number. But in all machines the main thing is to avoid injurious sparking, and this condition becomes very difficult of attainment when a curve of sines represents the induction. *En passant*, we are unable to discover the value of Isenbeck's experiments as far as modern dynamo design is concerned. Nor can we find anything in present day machines to correspond with the archæological appliances sketched in Figs. 42 and 53.

In Chapter V., the reactions in the armature and magnetic field are dealt with, and at page 91 some extraordinary figures are given. The fact of Strömberg obtaining a greater demagnetising *effect* due to the armature as the field-magnet excitement was increased, is quite inexplicable. We do not see that such an effect could be produced by the field-magnets being of inferior quality or section, as the professor suggests. In such a case we might naturally suppose that the effect produced by a given armature current would be the same whether the magnet excitement were greater or less, but we are by such a supposition left as far as ever from a reason for the demagnetising effect increasing with an increased excitement. The language here is most ambiguous. "With 13,400 ampere-turns," the passage reads, "the demagnetising effect of 60 amperes in the armature was equivalent to 4,400 ampere-turns. With 25,200 ampere-turns the demagnetising effect of only 30·5 amperes was equivalent to 3,100 ampere-turns." What were the conditions of lead to the brushes? The author does not know. Does the passage mean that the field-magnet excitements required to produce given E.M.F.'s on open circuit have to be increased by 4,400 and 3,100 ampere-turns respectively when currents of 60 amperes and 30·5 amperes flowed through the armature? We are not told. But if this is the true meaning, the facts do not prove that "with stronger constant excitation of the field-magnets the demagnetising effect of the armature currents was greater." We cannot say whether it was greater or less until we see the saturation curve of the machine, for effect stated in ampere-turns and demagnetising effect are certainly not the same thing. The reader is left to guess at the meaning as best he may, and we may fitly ask, Why publish these apparently anomalous results obtained under conditions unknown? Is the students' perplexity likely to be lessened by their contemplation? Or if the author is unable to explain the facts, does he imagine that a tyro, plodding through his book for the first time, is likely to unravel them?

Chapter VI. deals with the different methods of governing dynamos, while in Chapters VII.—XIII. are described all the best known continuous and alternating-current machines.

Chapter XIV. deals with the principles of magnetism, leading up to the idea of the magnetic circuit, and giving, finally, a very complete series of sketches showing the various forms of field-magnets employed in practice. There is given on page 304 a formidable array of empirical formulæ, which have been invented at various times to fit the dynamo. These empirical formulæ may be ornamental, but they are all uniformly useless. It seems to us somewhat absurd that time and tissue should be wasted in fabricating such formulæ when we have the actual curves, as on page 300, from which can be measured directly the function of the induction which gives the ampere-turns required per centimetre length. The writer later on, at page 319, adopts the formulæ of the Brothers Hopkinson, and shows how they construct the characteristic from a knowledge of the dimensions of the machine. It may be observed here that though the advantage, pointed out by the author, of round over square bars for magnets is well known, we see round bars less frequently than rectangular ones. The reason is that when round bars are employed there must always be separate pole-pieces, and that rectangular bars lend themselves most readily to the designs most frequently seen. As a matter of fact, the design must be considered in its totality, and though the magnet-coils cost more with rectangular bars, there may be on the whole an actual saving in the machine over one having round bars and cast pole-pieces.

In Chapter XV. is developed the elementary theory of the dynamo, and in Chapters XVI.—XX. are given the characteristics of magneto, series, and shunt machines. The author is very far from clear regarding the reactions of the armature on the magnets. In a vague sort of way he states that there is a weakening of the field due to the current in the armature, but as many electricians, let alone students, fail to understand the exact nature of this reaction, there ought to be no ambiguity concerning it. The magnetic circuits should be drawn, and it should be clearly shown that the windings of the armature act on the circuits in the reverse direction to the magnetising coils when there is a lead given to the brushes. Though we observe that in several places the author deals with the phenomenon of

Digitized by Google

self-induction, we do not see that he gives any hint as to the magnitude of the effect produced by self-induction in armatures of various kinds. This is surely an unfortunate omission, as the weakening effects before referred to, combined with the effect of self-induction, are so great as to render valueless the equations for compound-winding given later on. In ordinary sized machines compounded for constant potential, the series ampere-turns required on the field-magnets are from 50 to 100 per cent. greater than the formulæ give, while in large machines the weakening effect becomes enormously important, and the turns required may be 200 per cent. greater than indicated.

We are rather at a loss to discover the professor's drift in Chapter XIX. Having in a former place reduced the formulæ connecting the magnetising force with the induction to the simple form used by the Hopkinsons, he proceeds in the chapter under notice to develop a formula embodying an approximate law of the electromagnet discussed in a former chapter. The reader will very naturally enquire why the author doubles in this fashion, but we frankly confess our inability to satisfy his curiosity. The values given in Hopkinsons' curve are absolutely correct, that is admitted; the values given by the new formula are only approximate, that is conceded. The question is, why substitute with a view to accuracy something known to be untrue for something known to be correct, and why make assumptions in any shape or form when we can be guided by indisputable verity? We regard the "diacritical" number of ampere-turns as of no practical importance, nor can we find a single dynamo designer who takes any notice of it. It fitted very well into the formulæ which appeared in former editions of this work, but in our opinion it should now be relegated to the nirvana where the G, κ, H of other times, *et hoc genus omne*, find their everlasting repose. The last stage of inconsistency is reached when, farther on, the method of Hopkinson is employed to discover the values for coefficients to be inserted in the approximate formula.

It may be mentioned that, as a matter of fact, no equations for the curve of a series dynamo are required, and no one cares a straw about the shape of the curve at places other than those at which the machine is worked. What we have to do is to saturate the armature core to 18,000 or 20,000 C.G.S. lines, and pile up wire on the magnets to make the curve come down and ensure stability in the lamps. To do this, one finds the requisite magnetising force *à la* Hopkinson, and multiplies it simply by 2, a very easy operation, as will be admitted.

The method of treating alternating current dynamos adopted by the author might have been rendered clearer by a further use of graphic methods. Dividing modern alternating current machines into those with iron in their armature cores and those without, it may be said that no expression for the E.M.F. in the former can be given, because of the complicity of the reactions due to weakening effect and self-induction. At best the impressed E.M.F. required in order to produce a certain resultant E.M.F. has to be guessed at, and the relation of the former to the latter varies with each type of machine. On the other hand, the effect of self-induction and weakening in machines without iron is a small percentage, and, assuming that the resultant E.M.F. can be represented as a curve of sines, we can draw this curve, combine with it a curve of cosines to represent the E.M.F. due to self-induction, and build up from the two curves a third to represent the impressed E.M.F. We can then obtain from this third curve by measurement the strength of fields actually required for the impressed E.M.F. Chapter XXV. deals with transformers and motor-generators, the next seven chapters being devoted to the subject of motors. Much of the criticism previously made applies to this part of the work as well as to the part on dynamos, and we need not therefore deal with the chapters in detail. On the whole the matter is put pretty clearly before the reader, and the faults we have indicated can be easily remedied in future editions.

The student will find in this book a mine of information in which he may dig and be enriched, though he must not expect that with each exertion he will necessarily turn up a gem.

ELECTRIC LIGHT MEASUREMENTS.*

BY A. H. BATE AND E. GIMINGHAM.

With the rapid growth of electric lighting during the last seven or eight years there has arisen a demand for instruments measuring E.M.F. and current—and latterly for instruments measuring quantity of current—conveniently and with accuracy.

As far as ammeters and voltmeters are concerned, the problem may be said to be solved, at least for steady currents, but there is reason to believe that radical improvements will have to be made before we can give the public a thoroughly satisfactory coulombmeter.

With regard to ammeters and voltmeters, the problem has been a stiff one, because of the difficulties that are always met with in measuring very small forces accurately. Friction at pivots, torsion in suspensions, alterations due to temperature, and other small changes, are troublesome because their effect is not small compared with the feeble forces we are dealing with.

All electrical measuring instruments consume some power, and we can use this either as heat to stretch a wire or the magnetic effect to deflect a permanent magnet or soft iron needle, or we may use the dynamometer principle. There is only one practical voltmeter in which the current is used to produce heat—viz., Captain Cardew's, and, of course, Profs. Ayrton and Perry's modification.

Ammeters cannot be easily designed to work by heat. Prof. Forbes uses his convection current windmill for this purpose by hanging the moving part by a torsion wire and measuring the deflection. Several attempts—more or less successful—have been made to use this principle for ammeters. One inventor puts a thermometer in a coil and measures the rise of temperature when the current is passed, and another measures the bending of a strip made of two dissimilar metals. Mr. R. D. Smillie has patented an ammeter in which a strip of metal fixed at the ends is bent by being heated with the current in a way that strikingly resembles Profs. Ayrton and Perry's sag wire voltmeter The difference is that in this case the bending of the strip is measured instead of the true sag.

In volt and ampere meters which work on magnetic principles a choice has to be made between the dynamometer with small force and small errors and instruments in which soft iron or permanent magnets are used, and which, though their deflecting force is comparatively large, are subject to considerable inaccuracy.

Sir William Thomson has given us both ammeters and voltmeters controlled by gravity that are free from residual magnetism and almost all other errors. These instruments may be relied on as constant, and on varying standards with the same confidence that a foot rule may be. For laboratory standards nothing could be better than these dynamometer instruments. But for installation work we require an instrument which need not be accurate within about two per cent., but which must be easy to read. All dynamometer instruments have to be adjusted, either by moving a weight or bending a spring; and, although when making accurate observations it is as easy to turn a milled head, as it is to tap the case, an engine-room voltmeter must read directly, and should have large divisions.

To get large deflections and consume very little power is what we want, and the way to get this is to use soft iron. As a rule, instruments using soft iron give the same deflection as instruments without iron with one-third of the power. Such instruments as the Schuckert are well suited for engine-room work. The small piece of sheet iron which is sucked to the side of the coil retains very little residual magnetism

In the Schuckert voltmeter the divisions are only large at that part of the scale at which the instrument is intended to be used. Mr. Evershed has designed an instrument of the same type as the Schuckert, in which the field is modified by lumps of soft iron placed in the core; the object being to make the deflections equal throughout the scale. Although voltmeters of this type are liable to errors of, say, 2 or 3 per cent., we must remember that in the course of a few years lamps will probably be so much cheaper

* Paper read at the Students' Meeting of the Society of Telegraph Engineers and Electricians, December 6, 1888.

Digitized by Google

that users will be careless about a few volts; and then, we may safely predict that rough and cheap voltmeters will be most used, and that instrument makers who have spent money and brains in perfecting instruments in which simplicity is sacrificed to accuracy will be but poorly remunerated.

It is in the laboratory that pains must be taken to get extreme accuracy. If absolutely true standards are available, the engineer can be confident that his 2 per cent. error is never more. For this reason we think the engineer should be able to send his instruments to a standardising laboratory occasionally, where they should be calibrated at a small charge; or, better still, that he should have portable standards of his own with which he can check the instruments in position.

Fleming and Gimingham's voltmeter is in every way suitable for such work. This dynamometer is made in a case about 4in. (cube), and the whole instrument only weighs 2¾lb. There is no reason why this instrument should not be as reliable as any dynamometer controlled by gravity, since a spring is considered by the best authorities to be absolutely constant.

It is very difficult to make an ammeter on the dynamometer principle which shall be convenient to use as a portable standard. The difficulty in all current-measuring dynamometers is to get large currents into the moving coils. Neither of the two methods which are used are suitable for portable instruments; the mercury for obvious reasons, and Sir William Thomson's ligament because it can only be bent through a very small angle, and therefore requires a long pointer to give sufficient indications. Perhaps the easiest way of measuring current with a dynamometer instrument is to pass the current through a low resistance—such as $\frac{1}{10}$th of an ohm—and measure the volts at the terminals with a low-reading dynamometer voltmeter.

Beside their accuracy, dynamometers have this great advantage over all instruments which contain iron—that they can be used for both alternate and continuous currents. No soft iron instrument will measure alternate currents correctly, unless it is specially calibrated for currents of the periodicty it is measuring.

For central station work, where the current has always the same period, soft iron may be used without inconvenience. It seems to be the rule in instruments designed to measure alternate currents to use a comparatively large mass of iron well laminated. Mr. Westinghouse uses a well laminated core of soft iron wires, which is sucked into a coil, in both ampere and voltmeters, for alternate currents.

A "potential indicator" for use at central stations, and designed on the same principle, is very interesting. Two coils, one of which carries current from a transformer on the mains, and the other volts reduced by a transformer, pull against one another on two soft iron cores hung from a balanced beam. A counterbalance weight is set on the beam so that it just balances the pull of the volt coil when normal volts are on, and when no current is passing through the mains. Thus, when a current is taken through the mains more volts have to be put on to keep the balance. In this way the fall of potential due to the current is allowed for. In looking up this subject we have come across several ingenious devices which, though they may be only curiosities, are worth mentioning.

In 1884 Miller patented a device which can be used as either a voltmeter or ammeter, made as follows: A piece of soft iron sucked into a coil is made to displace a liquid, and the amount of displacement is measured in a capillary tube.

An ammeter has been made consisting of a U-shaped tube placed between magnet poles containing mercury, which carries the current, and is more or less displaced by the current. Great attention has been paid to the errors due to the heating of a wire in a voltmeter, and some devices have been patented which are intended to compensate for temperature changes.

All these compensating arrangements, however, only compensate for outside changes of temperature, and the real trouble is with changes due to the coil being warmed by the current. By making a Cardew voltmeter case two-thirds of brass and one-third of iron, we can avoid all errors due to temperature changes which affect the whole instrument; but this does not diminish the error due to the wire warming the case. In a similar way the resistance of a voltmeter coil can be kept constant by making part of the conductor of carbon as long as the carbon and metallic parts of the conductor are at the same temperature. But when the current passes, the heat produced in the two parts of the coil depends on their specific resistances, and not on their temperature coefficients.

Seeing that there is likely to be a much larger demand for good coulombmeters than there ever has or will be for ampere and voltmeters, it is not surprising that great attention has been paid to this subject. It is only surprising that, as the result of so much work and so many patents, there are so few practical meters. *A perfect coulombmeter* measures the current as accurately when one lamp is put on as it does for 100 lamps. Its moving parts must be so few and simple that it cannot get out of order, and the force employed must not be so small as to necessitate carefully made pivots, which get damaged by damp and dirt.

The great difficulty which is found in designing a meter indicating by dials arises from the fact that the motion produced by the current must be proportional to the strength of the current.

We may make coulombmeters on one of three principles. If the magnetic effect is not used, we must employ either heat or chemical action. Of these, magnetic meters are necessarily most complicated, because when once the field has been set up the current does no more, and some arrangement of clockwork is required to register the strength of the field and how long it is maintained. In coulombmeters which work by heat or by chemical action the effect is continuous, and clockwork is not needed.

It is difficult to use the chemical action of the current because the whole of the current cannot be passed through the voltmeter, and shunting a part of it through is not allowable.

Mr. Swinburne has patented a voltameter meter, in which this difficulty is overcome by using the current to move an iron core. The motion of this core alters the resistance of the shunt circuit in which the voltmeter is placed. As early as 1882 Mr. Ferranti used an induction coil or transformer on the main house wire of an alternate current system, and measured the alternate current produced by a voltmeter arrangement. Prof. Forbes has designed two forms of meter in which the heat of the current is used. In the convection current windmill the reading is proportional to the current, because, though the heat varies as the current squared, the convection currents are proportional to the square root of the heat. In Prof. Forbes' other meter the heat of the current is made to evaporate water, which condenses, and is measured. The water condensed is a measure of the current. Mr. Edison in 1882, Prof. Blyth in 1885, and Weston in 1886, have patented meters depending on Faraday's disc dynamo principle. In these meters the current is led in and out of the rotating disc by mercury.

It is easy to see that Mr. Ferranti's meter is on the same principle, only his whole disc is made of mercury. A shallow round tray contains mercury, through which the current passes radially. This disc of mercury is placed between the poles of soft iron electromagnets wound with current coils, but having also a small volt coil to give sufficient initial magnetisation. A vane pivoted in the mercury takes the motion as the mercury rotates, and a simple chain of dials registers this motion. Dr. Aron's meter consists of a pendulum (actuated by clockwork) which swings a heavy piece of soft iron over a flat coil carrying the current This meter contains two clocks, one of which is controlled by gravity, and the other by the current. An ingenious arrangement registers the difference in the rate of these two clocks, and indicates it by dials.

Mr. Sprague has invented a most ingenious meter depending on the deposition of metal. Between two copper electrodes, from which the current is passed, there is a copper cylinder free to rotate in the liquid. The current passes through the cylinder (as the path of least resistance), depositing copper on one side and removing copper from

Digitized by Google

the other side. In this way the centre of gravity is disturbed, and the cylinder slowly rotates.

A great number of meters have been designed which, however ingenious they may be, are either too complicated for practical use or are faulty in principle. The pull of a solenoid on a soft iron core has been made to govern clockwork by shortening the pendulum, or the hairspring of a clock, or to govern the flow of water through a valve. In one voltmeter meter, for alternate currents, the current is measured by weighing the copper disintegrated from the electrodes.

ELECTRIC LIGHTING IN LONDON.

The following, from the pen of Mr. R. Hammond, appeared in the *Times* of January 3 :

With reference to the statement in to-day's newspapers to the effect that the Board of Trade, in virtue of the powers vested in it by the Electric Lighting Acts, has decided to grant no licenses in the metropolitan area, I beg to call your attention to the following correspondence with the Board of Trade on the subject :

"Dec. 28, 1888.

"Sir,—I beg to hand you herewith a report of the proceedings at the general meeting of the London Electric Supply Corporation, Limited, and to draw your attention to a statement of the chairman therein contained that 'within the last fortnight the Board of Trade has decided not to grant licenses to anybody in the metropolis.'

"I should esteem it a favour if you would kindly inform us whether any action has been taken by the Board of Trade justifying this announcement.

"I am, sir, your obedient servant,

"ROBERT HAMMOND.

"H. G. Calcraft, Esq., C.B., Secretary to the Board of Trade, Whitehall-gardens, S.W."

"Board of Trade, Railway Department, London, S.W., Dec. 29, 1888.

"Electric Lighting Acts, 1882 and 1888.

"Sir,—I am directed by the Board of Trade to acknowledge the receipt of your letter of the 28th inst., inquiring whether any action has been taken by this department to justify the announcement that the Board of Trade has decided not to grant licenses to anybody in the metropolis.

"In reply, I am to state that the only decision at which the Board of Trade have arrived, with respect to applications for licenses in the metropolis, is that announced in the letters addressed by this department to the London Electric Supply Corporation, Limited, and the Metropolitan Electric Supply Company, Limited.

"From these it will be seen that the only decision that the Board of Trade has come to is not to grant licenses to companies for extensive and important areas in the metropolis. "I am, sir, your obedient servant,

"HENRY G. CALCRAFT.

"R. Hammond, Esq., House-to-House Electric Light Supply Company, Limited, 117, Bishopsgate-street Within, E.C."

From this announcement it will appear that the statement published in the Press is incorrect, and that the Board of Trade is actuated to-day by the same policy as that which it enunciated in its letter of the 17th of August, 1883—*i.e.*, that a license is the form of tenure under the Electric Lighting Act properly applicable to small areas, whereas large areas can only be properly dealt with by means of provisional orders.

The question, therefore, which the Board of Trade and the local authorities have now to decide is whether the time has arrived when, in the public interest, the metropolis shall be dealt with by the allotment of large areas to certain electric light companies under a 42 years' tenure, or whether it would not be a more prudent course, in the present state of the industry, to insist that those companies that are applying for this permanent form of privilege should, in lieu thereof, be granted licenses for a short number of years and for limited areas, in order that the merit of their pretensions may be tested by a probational period of working.

As one who has taken from the beginning an active part in the development of the industry of house-to-house lighting by electricity, I take this opportunity of stating some of the grounds upon which it may be advisable for the local authorities and the Board of Trade to grant licenses for limited periods and for limited areas in the metropolis in preference to provisional orders giving a 42 years' tenure :

1. No district lighting has up to the present time been carried out in the metropolis of so satisfactory a nature as to warrant the Board of Trade and the local authorities in proceeding at once to the apportionment of the metropolitan area by means of provisional orders, and no district lighting whatever has been carried out over an extended area by means of underground mains—the mode of distribution contemplated by the Act.

2. It would very prejudicial to the interests of the public to be served by electric light companies who were unable to thoroughly carry out the work, and until the new crop of electric light companies in the field have proved by natural selection which is the fittest, no 42 years' tenure in the metropolis should be granted at all.

3. It is urged by many that the electric lighting of the metropolis has been sufficiently long delayed, and that if it be still further delayed in order to discover which are the best supply companies, the interests of the consumers will suffer; but the fact is that the work carried out under licenses, say, within the first 12 months, will be quite as extensive as that which would be carried out in the same period under provisional orders.

4. Under the provisions of the Electric Lighting Acts the companies intending to apply for provisional orders have to give notice of their intention to do so prior to the 1st of July in each year, and it happens that only two companies had the temerity in June last to apply for the metropolis *en bloc*, and the immediate apportionment of the metropolitan area by means of provisional orders would practically lead to that area being handed over to these two companies, irrespective of whatever knowledge and experience may be available for the public at the hands of those companies which such an apportionment would exclude.

5. If in any form the electric lighting of the metropolis is to become the province of the new county council, it would be as well that until that body gets to work no action on the part of the Board of Trade or the local authorities should tie its hands by granting extended privileges to so limited a number of supply companies as that indicated above.

There are many other considerations of a technical nature which I refrain from touching upon, as I feel that I have already sufficiently trespassed upon your valuable space, but I may mention, in conclusion, that so little is apparently known in England as to the erection of central electric lighting stations that one of the two companies seeking for powers in the metropolis has actually given out the order for the erection of its first station to an American firm, though from a recent visit which I personally made to America I am disposed to agree with those English electrical engineers who believe that there is no reason why, with the splendid apparatus now being manufactured in England, first-class work cannot be done by English firms.

The strong plea that I set forth in this letter is that time should be given to prove which is the best supply company or companies in the field before giving permanent tenure to any.

"Journal" of the Society.—The last number of the *Journal* of the Society of Telegraph-Engineers, just issued, contain reports of the papers and discussions in the following subjects: "Ocean Temperatures in Relation to Submarine Cables," by William Lant Carpenter, with a sheet containing numerous illustrations and diagrams ; and on "A System of Electrical Distribution," by Henry Edmunds. The reply of Mr. Edmunds is not included.

THE

ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders, for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical-Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

PROSPECTIVE AND RETROSPECTIVE.

A HAPPY AND PROSPEROUS NEW YEAR.

There can be no better time than the beginning of a new year to take stock and think over the might have been. Æsop used to write or recount fables with a moral at the end. Parsons preach sermons and tag on the moral. The fond parent tells a doleful tale to his or her child about what happened to Budge or Dot through eating unripe fruit, with the inevitable moral, don't! Can't we have the moral without the preaching? What a lot of time would be saved in talking or writing, but no, it is the custom, and custom is a slave-driving operation that puts to shame all kinds of whips and scorpions. So then we have to find a moral, and, as accessory to this, to preach a sermon. What a nuisance books are that have no index, and what a nuisance indexes are that do not point out! We desired to give Mark Twain's version of "go to the ant thou sluggard, consider her ways and be wise," and after some trouble, his "Tramp Abroad" having no index, the following extract is found. But first to give a clue to the drift of the context of the part not extracted. The humourist describes a scientific investigation as to how far the life of the modern ant conforms to Solomon's ideal, part of which depicts an ant's action after finding what is evidently thought to be a grand prize. The finder does not get home with his booty, but "finally stops to rest, and a friend comes along. Evidently the friend remarks that a last year's grasshopper's leg is a very noble acquisition, and enquires where he got it. Evidently the proprietor does not remember exactly where he did get it, but thinks he got it around here somewhere. Evidently the friend contracts to help him freight it home. Then, with a judgment peculiarly antic (pun not intentional), they take hold of opposite ends of that grasshopper leg and begin to tug with all their might in opposite directions. Presently they take a rest and confer together. They decide that something is wrong, they can't make out what. Then they go at it again just as before. Same result. Mutual recriminations follow. Evidently each accuses the other of being an obstructionist. They warm up, and the dispute ends in a fight. They lock themselves together and chew each other's jaws for a while, then they roll and tumble on the ground, till one loses a horn or a leg and has to haul off for repairs. They make up and go to work again in the same old insane way, but the crippled ant is at a disadvantage; try as he may, the other one drags off the booty and him at the end of it. Instead of giving up, he hangs on, and gets his shins bruised against every obstruction that comes in the way. By-and-by, when that grasshopper leg has been dragged all over the same old ground once more, it is finally dumped at about the spot where it originally lay. The two perspiring ants inspect

Digitized by Google

it thoughtfully, and decide that dried grasshopper legs are a poor sort of property after all, and then each starts off in a different direction to see if he can't find an old nail or something else that is heavy enough to afford entertainment, and at the same time valueless enough to make an ant want to own it. . . . Science has recently discovered that the ant does not lay up anything for winter use. This will knock him out of literature to some extent. He does not work except when people are looking, and only then when the observer has a green, naturalistic look and seems to be taking notes. This amounts to deception, and will injure him for the Sunday school. He has not judgment enough to know what is good to eat from what isn't. This amounts to ignorance, and will impair the world's respect for him. He cannot stroll around a stump and find his way home again. This amounts to idiocy, and once the damaging fact is established, thoughtful people will cease to look up to him, the sentimental will cease to fondle him. His vaunted industry is but a vanity and of no effect, since he never gets home with anything he starts with. This disposes of the last remnant of his reputation, and wholly destroys his main usefulness as a moral agent, since it will not make the sluggard go to him any more." You see even Mark Twain is compelled to pin his moral at the end of his tale. There is, however, one among many good points in Mark Twain's story that commends itself to us. He blackguards the ant through the whole gamut, yet no individual ant feels aggrieved at his personalties. When the writer on technical subjects does not, as well as when he does, touch the question of personality, someone is sure to fit on the cap and say the remarks were directed against him. It is necessary, then, to guard ourselves, and to say that in what follows no individual is aimed at or thought of: the general question alone is discussed. In our view—restricting that view for the moment to London—the analogue of the grasshopper's leg is the profit from the public who want light and power; the analogue of the ants is to be found in the companies who are all pitching their tents in one district, and going to pull at that profit from each and several standpoints. Result, after struggles greater in proportion than those of the ants : disputes, legal fights, and—none of the profits. Details are unnecessary. In several parts of London two or more companies are preparing for competition. If they think this business-like, and leading to long-continued prosperity, their views differ from ours. Overhead wires except as pioneer wires will not be tolerated beyond a certain point, and householders will not put up with having the paths and roads in front of their places of business pulled up to suit the convenience of competing companies. Two or three competitors in the same street means far greater initial expense, increased cost of maintenance, and revenue per unit cut down to the uttermost farthing in order to get all the trade possible. What is happening now on a small scale, will happen on a larger. Private installations are being connected with central stations, and the small central stations will by-and-by be connected to the larger ones. The expense gone to at some of these small central stations will never be recouped, for they will have to give way long before they have paid for themselves. The gas companies imagine a maximum supply as will be required in the future and lay mains accordingly, the electric companies lay mains for the minimum supply and have little margin for increase; the latter act as if they expected a short and merry life, while the former act as if they meant to stay. No doubt the refusal of the Board of Trade, so far as London is concerned, to grant licenses, and to act only by provisional orders, is an attempt to restrict company action within definite limits, but central station work requires neither license nor provisional order. Any company can at any point install a station, whether the ground is already occupied or not, and if it can obtain the requisite wayleaves and orders, can get to work. We had intended to obtain a moral from almost every sentence in Mark Twain's tale, but perhaps that we have indicated is sufficient for the present to provide thought for the thoughtful. Unfortunately, every company imagines that its peculiar position or the influence of its directors places it in a more advantageous position than any other entering into competition, therefore the plainest sermon with the most direct lesson is not likely to have much effect.

It will be admitted that in the abstract we are right, while in the concrete a few energetic men think they can see a way to make money, and, like the ant and his prize, their friends flock in to help carry away the money in view. They don't always get it, but that is a mere detail. Prospectively, then, if these schemes are persisted in, there are troubles and squabbles ahead, and plenty of work for the legal fraternity in London. But, bird of evil omen, avaunt! Turn we now to something of a more pleasing character. The past year has been one of revival in the electrical industries. On every hand we hear of work completed, in progress, and contemplation. Dozens of small and large central stations are in progress, the most important of which is that at Deptford, belonging to the London Electric Supply Company, while the Metropolitan Company is hurrying forward several smaller stations, which, however, in the aggregate will be of no mean capacity. Kensington, Chelsea, Notting Hill, Westminster, St. James's Oxford-street, Holborn, the City, in North London, and elsewhere about the metropolis, stations are being erected or designed. Before the middle of this year we fancy an aggregate of at least

Digitized by Google

a million lamps will be provided for. We could wish that one half as much attention was being paid to the distribution of power as is being paid to the distribution of light, and then, with due consideration against excessive competition, there would be such a development of the industry as never was seen in any industry before.

The rapid increase of central stations for the distribution of light and power will necessitate some conclusion being arrived at with regard to overhead wires. At the present time a special committee has been appointed by the General Purposes Committee of the Birmingham Corporation to consider this question. Among all the conflicting utterances which have appeared upon this subject, the suggestion of Lord Crawford seems perhaps to be the one which will best solve the problem. We have already referred to this in a brief note, but the idea cannot be too much discussed, and we trust the Birmingham committee will give it due consideration. Undoubtedly the ultimate place for all wires connected with the electrical industries will be underground, so far as these wires are laid in populous centres, but to insist upon their being placed underground from the commencement might, and probably would, act disadvantageously to the development of the industry. Suppose a central station started with orders for lights in the immediate vicinity and with one or two orders at a considerable distance, the mains immediately surrounding the station where the great bulk of the lights are required, should be placed underground; but no business men would be tempted to invest their money to supply the individual orders at a distance if it were necessary to go to the expense of allowing heavy mains the whole distance underground. Lord Crawford's suggestion is to the effect that the supply company should be permitted in cases of this kind to run, temporarily, overhead mains to supply these distant points, and probably there would be a gradual desire along the line to add to the number of lights to be supplied. In a short time the demand would be perhaps sufficient to warrant the permanent mains being laid, but at any rate there should be a limit to the time during which the temporary wires might be used. The limit suggested has been three years, but it seems to us that if some such scheme as this were adopted it would benefit not only the trade, but those who desired to obtain the light and the power as quickly as possible. Readers may moralise upon the two points—"Excessive Competition" and "Pioneer Overhead Wires."

Before passing in review the work of individual firms, there is just one other question we should like to refer to, and that is the unfair manner in which our contemporaries devoted to gas, criticise electric lighting. We shall have something to say relative to Leamington and Barnet next week. Our contention is that the lighting in both places is better than it was with gas. Those who can only damn altogether or damn with faint praise are those whose inspiration is drawn from tainted waters, or who have received no inspiration at all other than their own inner consciousness. We have made it our business to send special representatives over and over again to see the lighting at one or the other place, and in every case the conclusion has been favourable to the electric light.

The following brief information about the work of individual firms shows that most of those engaged in the industry have been fairly busy during the past year, and that the prospect for the ensuing year is good:

Anglo-American Brush Company.—This corporation has been pioneer during the past year of very extensive and enterprising work both at home and abroad. The great resuscitation of the electrical industry following close upon the amendment of the Electric Lighting Act has had the effect, as was fully expected, of creating a demand for the supply of current for light and power from central generating stations. Foreseeing this, the corporation have studied carefully and successfully the production and perfection of the most efficient and economical plant for the purpose. So far from limiting themselves to any particular system of generation, they have noted the requirements of each individual case, and have installed the most suitable system in each instance. Their central station installations afford examples of the high-tension alternating current system, the low-tension continuous current system, the high-tension continuous current system, and also of the high-tension continuous current system in conjunction with accumulators.

The corporation's alternating current system has been eminently successful, and the demand for its adoption has so increased that they have found it necessary to equip their works for the more extensive production of this apparatus. This system is well exemplified by Messrs. Pritchett and Company's Oxford-street central station, Rathbone-place, Oxford-street, which has worked successfully for nearly a year, and has given entire satisfaction. We are informed that they now have orders in hand for apparatus of this system for installation in a number of central stations both in the United Kingdom and abroad, amongst which may be mentioned those of Lynton and Okehampton in Devon and Tucuman in the Argentine Republic. The central station at Bournemouth, on which the corporation are now engaged, will be worked by the Mordey Victoria alternators, which will, in the first instance, supply 2,000 lamps of 17 c.p., an output that can be increased whenever the demand calls for its extension. We understand that the corporation will supply their machinery and apparatus to the central station of the Chelsea Electricity Supply Company, which is now approaching completion. The apparatus will be worked in conjunction with E.P.S. accumulators, and it is believed that this installation will be a model for central stations on the system of accumulator distribution. An interesting example of central station low-tension distribution has been carried out by the corporation through their Italian agent at Novara; it is on the three-wire system, and has operated so successfully that it has been decided to considerably increase the capacity of the plant.

In exhibition lighting the work of the corporation maintains its excellence. The installation carried out by them at the Glasgow Exhibition of 1888 comprised over 500 arc lamps, by which the exclusive lighting of the main building and ground was effected, the whole of which lighting worked through the entire term of the exhibition without a single hitch, and was universally admired. Incandescent lamps were also supplied to numerous private

Digitized by Google

consumers from their exhibit installation. In the Melbourne Exhibition of 1888 the corporation also supplied, through their Australian agents, the whole of the lighting plant, comprising dynamo machines and all accessories for an installation of about 800 arc lamps of 2,000 c.p., and machines for 3,000 incandescent lamps of 17 c.p., the illumination being most satisfactory, and the plant supplied running uninterruptedly throughout the six months. The fact that the whole of the apparatus for this large installation was constructed and shipped under a penalty contract within six weeks from the date on which the order was placed, affords a comprehensive estimate of the corporation's resources in the designing and expeditious manufacture of their plant. We should also mention that at the Barcelona Exhibition of 1888 a most successful "fairy fountain" installation was carried out by the corporation, which proved a great attraction, and is generally considered to be the most perfect example of the kind that has yet been effected. In ship-lighting, business has been fairly brisk, and among the larger contracts which they have carried out in this branch are those for the complete lighting of the "Rosslyn Castle," the "Norham Castle," and the "Hawarden Castle," vessels belonging to Sir Donald Currie and Co. A number of their combined plants, constructed for installation on shipboard, have also been supplied to the Pacific Steam Navigation Company, Liverpool. This apparatus is very compact, and the corporation have supplied a large number of sets to the principal European Governments for installation on shipboard, and other situations where economy of space is a consideration.

In the design and construction of motors and other appliances for the electrical transmission of power they have bestowed much thought and attention, and, amongst other undertakings, they have entered into a contract for the application of electricity by overhead conductors to an extensive tramway system in Spain, which presents features of exceptional difficulty in sharp curves, steep gradients, etc.

From a large number of installations in public buildings, mills, factories, mansions, etc., carried out during the past year, we may select as particular instances the following: Blenheim Palace, the residence of the Duke of Marlborough, and "Clova," Ripon, the residence of Prof. Piazzi Smythe.

In export trade the corporation have done a large business, shipping their apparatus to all parts of the world.

The famous action of the Edison-Swan Electric Light Company *v.* Holland and others, defended by the Brush Corporation, has now become matter of history, and the decision of the court in the appeal which has followed the action is awaited by the corporation with every feeling of confidence.

In the case brought by them against the Orient Steamship Company for the use of dynamos which infringed the Brush Corporation's compound-winding patent, the judgment of Mr. Justice Chitty is of great importance, establishing as it does the validity of their patent, which, though acknowledged by all the principal dynamo makers in this country, had not been contested in a court of law.

Their Scottish action with reference to compound winding has only been partly heard, but will probably be determined at an early date.

GOOLDEN AND CO.—Messrs. W. T. Goolden and Co. have had a very busy year, not having experienced slackness in the summer months, which has been a usual experience in former years with electrical manufacturers. They have been occupied with considerable orders for the Admiralty and India Office, in theatre lighting and mill and house installation work, and have been very busy with installations for transmission of power. Alternating-current plant—both dynamos and transformers—have been added to their list of productions some large alternating machines having been built. They have also been engaged in tramway work, utilising waste water-power. In the instrument department a corresponding activity has prevailed, and the "Evershed" and "Cardew" instruments have met with considerable appreciation from contractors as well as private customers. In order to cope with the great increase of business, they have recently removed into large and commodious premises in Woodfield-road, Harrow-road, London, specially arranged and fitted for the business, and have largely increased their plant, with a view to producing machinery and electrical instruments, and other work, on the most modern system of manufacturing.

HAMMOND AND CO.—During the past year this firm has continued to devote itself almost exclusively to central station lighting. They have considerably enlarged their operations at Brighton and Eastbourne. At the latter place they are still working, as they have been working for the past six years, with a system of underground mains for high-tension currents, which system is attracting at the present time a great deal of attention; the installation there being probably the only one in the world where such an extensive area is served by means of underground mains.

They have also in the past year founded the House-to-House Electric Light Supply Company, which bids fair to take a very good position in the electric lighting world, and has distanced all its rivals by the rapidity with which it laid down its Kensington station. On the last day of the year the boilers and engines started to run, and the current can now be supplied. A full description of these works will appear in a later issue.

Hammond and Co. have already been chosen by the Great Northern Railway Company to do their electric lighting at the new shops in course of erection at Doncaster.

IMMISCH AND CO.—During the past year Messrs. Immisch and Co. have been steadily increasing their business.

There has been an increased demand for motors for isolated installations, but motors used in connection with central stations do not seem to be in demand. This, however, will probably be altered as the number of central installations increases.

The firm have given particular attention to motors for mining purposes, and have three plants ready for erection now—one in Yorkshire (a repeat order), one in South Wales, and one in Scotland.

Experiments have also been made with a self-contained loco. at Wharncliffe-Silkstone Colliery, Yorkshire. The results are very promising, and seem to argue well for this class of traction. Attention has also been given to the application of motors to launches, and considerable progress has been made. At Henley last year the firm had a 30ft. launch called the "Malden," and since then have placed on the Thames the "Viscountess Bury," a superbly fitted pleasure boat 65ft. long, 10ft. beam, and a mean draught of about 3ft. This latter launch is specially designed for the accommodation of pleasure parties. She is fitted with twin propellers and motors, and will make about six knots an hour from some 10 to 12 hours. It is intended to place on the river a fleet of about eight to ten launches, most of which are now building, in the early part of the year, which will be let out on hire to pleasure parties. For the purpose of charging the accumulators, charging stations are being established at several points on the river, and there are two floating stations that can be moved to regattas or anywhere as may be required. Messrs. Immisch and Co. have supplied the five motors used on board the Spanish submarine boat, the "Peral." They have also supplied the dynamo for charging the 600 accumulators used for storing the energy. The firm has also been engaged with tramcar motors, several of which have been made for foreign orders. Six of these motors are being supplied to the Electric Traction Company for use on the North Metropolitan line between Canning Town and Barking. They have also made a dynamo of special design for charging the accumulators for the six cars. It is expected that the whole will be running by the middle of January. A fair number of dynamos have also been supplied by the firm for incandescent and arc lighting both at home and abroad. There has also been a considerable increase in the general work of the firm, and orders have been received for motors to be used in new directions, and this shows that the users of power generally are beginning to find out the value of this system.

LAING, WHARTON, AND DOWN.—This firm commenced the year at new and more commodious premises in New

Digitized by Google

Bond-street and Brook-street, and have found the move from Holborn-viaduct to be in every respect a good one. They have carried out a great deal of work, both large and small installations, and their staff is very much increased, so that their new premises are in some respects too small already. This refers more particularly to the showroom for artistic electric fittings, which was originally thought to give ample room, but there has been so much increased electric lighting that the demand for fittings has, of course, developed very considerably, and also the taste of the public has improved, and the old day of converted gas-brackets, etc., is rapidly disappearing. The firm finds that customers are becoming alive to the fact that the electric light can be charmingly combined with art.

The Thomson-Houston system, for which Messrs. Laing, Wharton, and Down are the agents, has made considerable strides in this country during the past year, and considerable contracts are being carried out for railway and dock companies, engineering works, breweries, etc. The installation on this system at the Italian Exhibition was extremely successful in every way, the 300 arc and 400 incandescent lamps having run without a single hitch for the six months. This installation naturally attracted a great deal of attention, and led to numerous enquiries and a considerable amount of work. The firm is to be congratulated in being able to say that in no single instance where a Thomson-Houston machine has been installed have they ever had the slightest complaint.

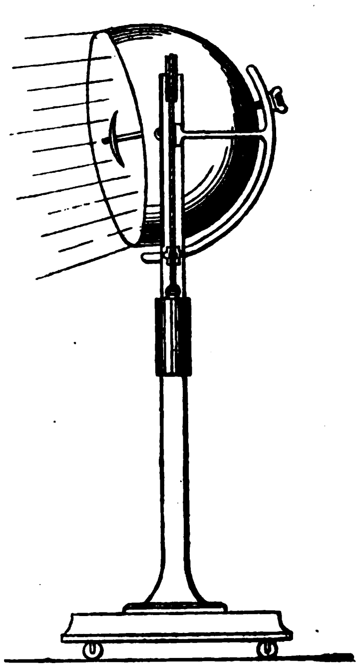
Mather and Platt.—The electrical engineering department of Messrs. Mather and Platt, of the Salford Iron Works, Manchester, has been very actively employed during the past year; the number of dynamos turned out has largely exceeded that of any other year. Among the more important of the installations for which they have manufactured the dynamos, we may mention the following: For the Adelphi Theatre, London, two large dynamos, each for an output of 1,300 lamps, and two smaller dynamos, each for an output of 800 lamps, all of the Edison-Hopkinson type, and driven by Willan's central-valve engines; two Edison-Hopkinson dynamos, for the central station of the Leeds Corporation, including the lighting of the Leeds Art Gallery and Municipal Buildings; two slow-speed Edison-Hopkinson dynamos, each of 1,000 lamps, for the mills of Messrs. Eckroyd and Co., Burnley; a special low potential Edison-Hopkinson dynamo, for Mr. Webster's new process of treating sewage. The firm has also supplied 15 dynamos for the Admiralty in conjunction with Willan's central valve engines and Westinghouse engines, and have manufactured the dynamos for Lord Rothschild's yacht, for lighting Lord Rosebery's country residence, for lighting the chemical laboratory at the University of Cambridge, as well as a very large number of dynamos for ship lighting, country house installations, and especially for cotton mills and weaving factories in the colonies and abroad.

Robey and Co.—Closely connected with electric lighting is the construction of good engines for driving dynamos. A number of firms are coming prominently into notice as makers of suitable engines, and, among others, we may mention Messrs. Robey and Co., who, at the Newcastle Exhibition of 1887, and at the extremely successful Glasgow Exhibition of last year, had a large display of engines. At the latter exhibition they had eight different engines of various classes specially suitable for electric light work under varying conditions. Among others, vertical and horizontal engines, with all their working parts running in a bath of oil, specially for ship lighting and other places where attention cannot be given to them; a small compound engine, only occupying about 4ft. square, and developing 30 h.p. at 500 revolutions per minute; and for permanent installations a 300 h.p. engine, which proved its thorough suitability for the work, by not only doing its own duty, but frequently that of its neighbours, during the whole of the exhibition without a moment's stoppage from any cause whatever. During the year the firm have supplied many engines for private installations, and work in this department has very considerably increased. Amongst them are a number fitted with their new class E trip gear, which has been illustrated in our pages, and also with their patent electric regulator. They have a number of engines on hand at the present time of large size working up to 250 h.p. each, three of them going, to a large electric installation in Australia, the machines for which have been manufactured by Messrs. Elwell-Parker, Limited, Wolverhampton, and as an illustration of the wide diffusion of electric light, Messrs. Robey and Co. are just supplying an engine and boiler for working 300 lights to a Roman Catholic monastery in Scotland. The firm expresses no doubt that electric lighting has become established on a commercial footing such as it never before occupied, and the demand for it is constantly increasing.

The Telegraph Manufacturing Company, Helsby, near Warrington, have been fully employed throughout the year. Insulated wires—both gutta-percha, indiarubber, silk, and cotton—are the chief articles of manufacture, and nearly 7,500 miles have been turned off during the year. Vulcanised rubber, electric light leads, for which the company have erected special plant, are being sold with first-class results, the shops now working overtime. The company have made during the year over a thousand railway telegraph instruments, also a large number of instruments for the postal telegraphs department, including automatic bi-polar relays, sounders, double current keys, single needle tapper commutators, etc. Domestic apparatus has also been sold in large quantities. The company have special facilities for turning out work of this class. The new patent telephone-magneto is in great demand, as also telephone material generally. The other departments—battery and insulator—have been constantly employed throughout the year.

PHOTOGRAPHIC ARC LAMPS.

In photographers' studios a great desideratum is that of a strong, convenient light suitable for taking photographs after dark, or on foggy days. The arc light has some very considerable advantages for taking photographs, and these in several cases have led to fashionable artists installing their own gas-engines and plant; in other cases the supply has been obtained from central stations.

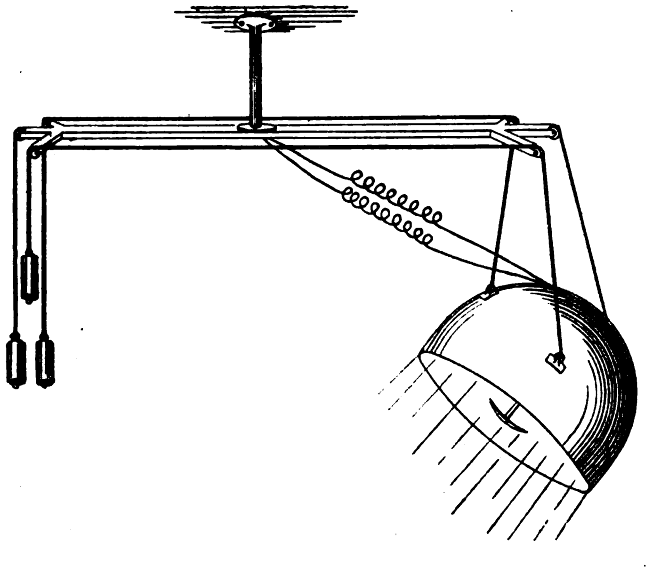


Faraday's Photographic Arc Lamp—Standard Pattern.

We illustrate herewith two arrangements for arc lights for photographers, constructed by Messrs. Faraday and Son, Berners-street, specially adapted for this purpose, one a hanging lamp, and the other a standard form of the same. The hanging lamp has been fitted at Mr. Bassano's studio in Bond-street, and consists of a large parabolic papier-maché reflector slung in the same manner as Sir David Salomon's "Perfect Pendant," manufactured by the same firm, with three cords of suspension, allowing of

Digitized by Google

motion up and down and alteration of direction in any angle. The reflector is counterbalanced by weights, each having an eyelet for easy manipulation by a hook, and the whole can be rotated upon a pivot, arranged at the bottom of the iron tube by which the whole is fastened to the ceiling.



Faraday's Photographic Arc Lamp—Sling Pattern.

The standard lamp shows a similar parabolic reflector, fitted so as to be adjusted up and down, and to be pointed in any direction. It is mounted upon a movable frame with castors by which it can be wheeled about the studio. The arc lamp used is constructed to work at any usual angle. The lamp requires about 30 amperes, and is about 5,000 nominal c.p.

TRAMWAY WORK.

In continuation of the information on the Bentley-Knight system, described at some length in our last issue, we give the gist of a pamphlet compiled by this company, and in the accompanying tables we give estimates as to the cost of a tramway on this system in New York.

It is the tendency of modern practice to concentrate the generation of power into large stationary plants where the utmost economy can be obtained. Power, heat, and light are all at the present time distributed from central stations by means of steam, gas, and electricity, the main contribution of the latter to modern industry being its adaptability to the distribution of energy from a central generating point.

In considering the application of electricity to locomotion, it must be viewed as a means of transferring energy from one point to another; the problem being to divide up the energy of a steam-engine at a station among the cars on a line, and to enable each car to receive and utilise, as it moves, the proper amount of current for its needs at any given point. In a cable railway, distribution of power is accomplished by a rope constantly dragged by the power of the engine over the whole length of the line, the cars gripping it at will. In an electric railway, the energy of the engine is converted into electricity and carried by stationary metallic conductors along the whole length of the line, and the cars, as they move, draw off the electricity by means of a constant sliding connection between each car and the conductors.

The electric current passes along its conductor without outward manifestation; there is no friction, no inertia, no appreciable heat; it can be taken off at any point and converted into power or into light. An idea of electricity, as a medium for transferring energy, may be had by remembering that an electric arc lamp represents about three-quarters of 1 h.p. of energy. If a lamp is removed from the circuit and replaced by a motor, we have the same energy in the form of motive or mechanical power. In some smelting furnaces electric heat is employed. A certain small amount of energy is lost in the conductor through which the electric current passes, heat being generated and radiated, but this loss in a well-constructed electric line never exceeds 5 per cent.

While the conveyance of electric power by means of a rod or wire of copper is very simple, it is a very difficult mechanical problem to convey the same amount of energy by a wire rope, as in the cable system. The weight of the cable must be moved, and it must be supported by sheaves placed along the line at short intervals, while a large tunnel must be built to contain it. The sheaves all consume power, must be constantly oiled and watched, and prevent any thorough cleansing of the conduit. Elaborate and complicated construction is necessary for curves and switches, while the connecting and disconnecting of a heavily loaded car to and from a swiftly moving cable is a difficult and wearing process. Cable engineers estimate that more than 75 per cent. of the engine-power is consumed in moving the dead-weight of the cable, and the cable itself rarely lasts a year.

When electricity is used, on the other hand, the conduit contains only stationary and permanent copper rods, and no mechanism is employed which can wear and give trouble. Connection between the motor on the car and the current supply in the conduit is maintained by means of a light sliding contact bearing gently against the conductors, and the conduit excavation need be only large enough to permit of drainage. So far as the transmission of power is concerned, the simplicity and convenience of the electrical method are unrivalled.

Its efficiency is equally satisfactory. The dynamo-electric machine, by which the power of the steam-engine is converted into electricity, has reached a degree of perfection scarcely appreciated. Less than five years ago the best dynamos gave an efficiency of 75 per cent.; there was an excessive heating of the wire coils and of the journals, so that a machine could rarely be depended upon for a run of 12 to 18 hours at a stretch. There were frequent burnings out of the armature and of the commutator, and other recurring faults which caused uncertainty and expense. At present the best manufacturers sell their machines, both dynamos and motors, with a guaranteed efficiency of 90 per cent; so that for every 100 h.p. of the steam-engine, 90 will appear on the line in electricity, and 81 will appear in the motor in the form of mechanical energy. The latest series of tests made with railway motors demonstrated an efficiency of 80 per cent. from the steam-engine to the car-axle. From this must be deducted in actual practice 5 per cent. for the conductors and 10 per cent. for contingencies of all kinds, leaving 65 per cent. actually to be relied on. Therefore, from 100 h.p. at the engine, 65 will be delivered on the car-axle.

The capacity of machines has increased in like ratio. A machine that would formerly operate 35 or 40 arc lamps has been worked up to operate 65. At the same time the reliability of machines has been improved. Their electrical and mechanical construction has been brought to such a degree of perfection that little more can be desired. While the electrical machines have been worked up to this point, special engines for driving them have been designed, and special appliances devised for protecting both dynamos and engines from all possible accidents and interruptions. This growth has been unostentatious, but rapid and sure, and at present the transmission of energy by electricity is thoroughly and completely practicable, thousands of horse-power being every day obtained from electric motors.

The application of the motor to railway use has been steadily developed during the last four years. Various difficulties have been met and overcome. The conduit system, involving greater difficulties and expense than the overhead system, has gone somewhat slower, but both are now in shape for practical everyday use. The peculiar adaptability of the electric motor to railway use is not fully appreciated except by those intimately acquainted with it.

The work of propelling a tramcar is characterised by wide variations in the amount and character of power required. The work is measured by the product of the

Oiling sheaves	—		—			4,000
Wear and tear	at 5%	7,200§	at 3%	13,860	at 3%	23,694¶
Maintaining cable	—		—			13,200
Interest, at 6 per cent.		12,240		27,720		48,180
Total		$107,040		$51,891		$101,210

* Car-bodies cost from $700 to $1,200. † Axles and wheels are included in motor-trucks. ‡ Including grip. ‖ From $50,000 to $100,000 per mile of track. Curves, crossings, and switches constitute a heavy additional expense. § $204,000 less $60,000 (cost of horses) ¶ $803,000 less $13,200 (cost of cable).

traction into the velocity, and there is found to be a variation in the total product required, and also a variation in each of the factors entering into it. A motor for street-car work must be capable of wide variation in traction, to correspond with the variations in grade on the line. The quite ordinary grade of 5 per cent., for instance, requires about eight times the traction that is necessary on a level.

For this reason motors that have but little range of pull or pressure must fail; for while, on a level, the pressure will be ample for the load, and will accelerate the speed so as to do a large amount of work, it will not give sufficient traction for a grade or curve. In an electric motor, on the other hand, the pull increases as the square of the current, and is limited only by the magnetic saturation of the iron cores. This limit is so remote that it is best appreciated by the fact that, in practice, a motor capable of moving 15 tons up a grade of 8 per cent. weighs, with its gearing, but 1,600lb. By admitting three times the current to the motor that is necessary on a level, the traction can be increased nine times.

It is another peculiar feature, that the necessary increase of current automatically takes place by reason of the tendency of the electric motor to slow up under an increased load. This slowing tendency and the acceleration due to the resulting increase of current meet each other at a point always dependent on the load at any given time. This follows from the following considerations: A dynamo and motor are the same machine working in converse ways, the dynamo converting mechanical into electrical energy, and the motor converting back electrical into mechanical energy. When acting as a dynamo, the machine has also a motor action, due to its own current, which opposes the driving-engine, and in overcoming which the power of the engine is consumed. When acting as a motor, on the other hand, it has also a dynamo action, tending to set up an E.M.F. against the direct or actuating E.M.F.

The efficiency of the transmission depends on the ratio between the direct and counter E.M.F's.; and, as the resistance of the motor is constant, the current through it will depend on the excess of one over the other. Any slowing of the speed, therefore, causes a large current to pass through the motor; and this produces a much greater traction, since the traction increases as the square of the current. There are other elements which come in to modify this result somewhat, but which we need not enter into. As a fact in practice, the traction automatically increases in a much greater ratio than the speed decreases, corresponding very closely with the variations in traction and speed that the service on most short railways demands. For the large majority of cases, therefore, the electric motor is nearly self-regulating, an artificial resistance being used for stopping, and occasionally for going very slow and restraining too high speed.

The great capacity and compactness of the electric motor are evident qualifications for tramway work.

ON THE ABSOLUTE VACUUM AS A NON-CONDUCTOR OF ELECTRICITY AND THE IMPORTANT BEARING OF THE FACT UPON ELECTRIC THEORIES.*

BY DR. P. H. VANDER WEYDE.

The historical exhibition which I furnished at the American Institute Fair of 1887 contained several series which for want of space could not be separately shown, as would have been desirable, if space had permitted. In fact, everything was to a great degree mixed up for the reason referred to.

Among these series electricity in vacuo formed a prominent and important feature, and because this is a subject so little understood, and even misunderstood, by the majority of electricians, and is also neglected in the text books, I felt induced to take this for my subject when I was requested to address the society.

An additional reason was that it is of some practical importance, not so much in regard to its mechanical applications, as for the understanding and explanation of a great number of natural phenomena.

I will treat the subject historically, and therefore begin by calling your attention to the experiments of Nollet, recorded in this little book, published in Paris 1753, and illustrated with carefully engraved figures. His experiments consisted in passing a current of static electricity through glass flasks, from which a large portion of the air had been previously removed by the air-pump. He found that the electric current passed as a luminous stream which was very bright when the room was darkened, while luminous pencils were thrown off toward the side of the flask if they were touched by the fingers or any other conductor of electricity.

Some thirty years later a variation of this experiment was contrived, consisting of a strong glass tube of about

* Paper read before the New York Electrical Society.

Digitized by Google

two or three inches diameter and three or more feet long, provided with brass caps at each end, which could be conveniently attached to the air-pump, and exhausted. As the exhaustion proceeded, the rarefied air in the tube became a conductor of electricity, while this conductivity appeared to improve in proportion as the air was more exhausted. At last a regular stream of electricity was seen to pass through the tube, which stream resembled strikingly the luminous coloured streams seen in the aurora borealis, wherefore such a tube was called the "aurora tube," and under that name is found in most philosophical collections.

This apparatus was exhibited at the fair, the exhibit consisting of an old historical air-pump, made about 1780, with the aurora tube screwed on the top of it. A few other smaller devices of a similar nature were less conspicuous, and about them I wish only to remark that when using an ordinary air-pump it appeared that the conductivity of the air increased in proportion to the amount of exhaustion; hence the impression became prevalent that if we could only obtain a perfect vacuum we would have the best of all conductors, and this idea is, unfortunately, even at the present day, shared by several prominent electricians who have not had the opportunity to keep themselves posted in regard to the discoveries made during the last few years, especially those made by Crookes, Gassiot, Spottiswoode, Gordon, and others.

I must not omit to mention that before the latter discoveries Geissler, in Germany, began to furnish investigators with a great variety of glass tubes of various fanciful shapes, made of different kinds of glass and filled with various gases and vapours, exhausted by the air-pump or by being heated, and then sealed up by the blow-pipe, while platinum or aluminium wires were inserted at the extreme ends, so as to conduct the electric current through the rarefied gases inside. As those tubes exhibited a series of striking and beautiful phenomena, they became very popular, and no physical collection is considered complete without a set of such tubes. They give occasion to exhibit the auroral phenomena, and similar ones of the same character, without the trouble of continually working the air-pump.

I had two sets of such tubes on exhibition at the fair—one was extra large, the tubes being three and four feet long, and another set of tubes as many inches in length, and which I shall have the pleasure to exhibit to you tonight, being much easier and safer to transport than large tubes.

I will now proceed to make a statement of the facts as they are. They are startling and difficult to explain without the knowledge of the new conceptions of Prof. Crookes regarding the nature of matter in the four different conditions, in which it presents itself to us.

The facts referred to are: The atmosphere in its ordinary condition is a very good non-conductor of electricity, provided it is perfectly dry and under a pressure equal to a mercurial barometric column of 760 millimetres or higher.

It is an important consideration, that if the air in which we live were a good conductor of electricity, man could never have become acquainted with electrical phenomena, as then static electricity could never have been collected, studied and experimented with; as this form of electricity was the key to the other different forms, the latter would never have been discovered.

When rarefied by the air-pump to a quarter of the normal pressure, the insulating qualities of air are not so good, and when reduced to a pressure of 10 or 20 millimetres it is a good conductor, and exhibits the phenomena referred to before. As this is about the limit attainable by an ordinary air-pump, it is very natural that experimenters became possessed of the idea stated above, that the conductivity of the air would keep on increasing as the exhaustion proceeded; but after the Sprengel mercurial air-pump was invented, by which the air can be exhausted to a thousandth of a millimetre of mercurial pressure (which is about equivalent to one-millionth part of ordinary atmospheric pressure), it was found that the capacity of the air to show the auroral phenomena in the usual way ceased.

The electric current then behaves in a very different manner, as it radiates in straight lines and cannot turn corners, so so when the tubes are bent it gives occasion to very striking and novel phenomena, which were first brought forward by Prof. Crookes in the tubes which are known by his name.

The difference between the Geissler tubes and the Crookes tubes is, that in the first the vacuum is very imperfect. In the Crookes tubes it is about a thousand times better, while if we succeed in making the vacuum a million times better, the conductivity of the air ceases absolutely. To accomplish this we must aid the function of the Sprengel air-pump by some chemical device which will remove the last remant of air. It then becomes an absolute non-conductor, which ordinary atmospheric air is not, because it is possible to pass currents of high tension in the form of an electric spark through the densest and driest air. In the absolute vacuum, however, it is impossible to pass, over the space of a quarter inch, a spark which, when leaping through air, will be six or more inches long.

I exhibit here such a tube in which the two platinum wires are brought together within a distance of scarcely a quarter inch. In this tube a vacuum did exist so perfect that it was impossible to pass a spark through, which through air would leap over a distance of more than six inches. I found that the spark would rather pass over the outside of the tube for that distance than go through the interior. In order to satisfy myself that no trace of electricity passed through the interior space of a quarter inch, I connected one of the platinum wires with a Leyden jar, wound a brass chain half way around the middle part of the tube, and connected this brass chain with the ground, in order to prevent any electricity from reaching the Leyden jar through the air along the outside, but I was not able to obtain the least trace of a charge in the Leyden jar. Later, I increased the strength of the current more and more, until at last something happened in the tube which destroyed the vacuum; something volatilised, covering the sides of the glass interior with a blackish deposit, which may perhaps be platinum black—a thing which may not be impossible, if we consider that the electric discharge furnishes us the highest temperature which we can possibly produce by any means.

For more than 20 years I have preached this non-conductibility of a perfect vacuum, as it was proved by experiments with the Ruhmkorff coil, by de la Rive and Du Moncel. The latter describes the experiments in his book "Sur l'appareil d'induction de Ruhmkorff," published in Paris about 25 years ago.

It has not a little surprised me that the priority of this discovery is so remote as I found it to be, and that so important a fact as that of the non-conducting power of a perfect vacuum has been overlooked and ignored for nearly a century after it was proved by experiment. I found in the "Philosophical Transactions" for 1785, page 272, vol. 75, the extract of a paper read by Morgan before the Royal Society, and which I published eight years ago in the *Practical American*, which I edited at that time. The paper referred to states that a mercurial gauge 15in. long, filled with pure mercury which was boiled in the glass until all air was expelled, was coated with tinfoil five inches down from its sealed end, and was inverted into the mercury in a little trough, through a perforation in its brass cap: the air over the mercury in the trough was then exhausted, when the mercury in the gauge fell down more or less in proportion to this exhaustion, but had always a perfect vacuum over it. If, then, the tinfoil coating the upper end of the tube was connected with the conductor of an electric machine, not the smallest ray of light nor the slightest charge could be produced in this exhausted gauge; but if the mercury had been imperfectly boiled, coloured luminous phenomena were seen. The same was the case when the sealed end of a perfectly exhausted tube became cracked so that a little air had access. At first the electric charge passed with a yellow or green light; more air made the colour a beautiful green, then blue, from blue to indigo; more air still, violet and purple, until the medium became so dense as to no longer conduct electricity. The writer closes with the observation: "I think there can be little doubt, from the above experiments, of the

Digitized by Google

non-conductive power of a perfect vacuum. This seems to prove that there is a limit even in the rarefication of air, which sets bounds to its conducting power; or, in other words, that the particles of air may be so far separated from each other as no longer to be able to transmit electricity; that if they are brought to within a certain distance of each other, their conducting power begins, and continually increases, till their approach also arrives at the limit."

It is also a fact, known for more than a century by expert barometer makers, that the luminosity which shows itself in the dark in its vacuum, when a barometer is moved up or down in order to cause the mercurial column to oscillate in the same way, is only seen when the mercury has been boiled in the tube to a moderate degree; when the vacuum is made too perfect it shows itself feebly, or not at all, the same as is the case when the vacuum is contaminated with watery vapours.

So much for facts; now for the theory which explains them, and for which we are indebted to Prof. Crookes. It gives us an inside view of the nature of matter in the conditions in which it presents itself to us, and is based on the theory of Dalton, that all matter consists of an immense number of infinitesimal particles called atoms, which are indestructible, and in continual motion, which latter is also indestructible.

Astronomy teaches that in the planetary system we find a condition of things which is far beyond our ordinary conception based on our experience about things falling under the daily, immediate observation of our senses. First, the distances at which the celestial objects are placed are immense in proportion to their size, stupendous as it appears to us. Secondly, they are in a continuous motion, which is indestructible. Every planetary system is to us a perfect "perpetuum mobileo."

Modern chemistry teaches the same doctrine in regard to ultimate atoms, which constitute that which we call matter. First, the distances of these atoms are also very large in proportion to their size, which is infinitesimally small beyond our conception; secondly, these small particles or atoms are also in a continuous everlasting motion, as indestructible as is the motion of the planetary bodies.

As a concise statement of the modern philosophical conceptions in regard to this subject, we say that, as the chemists of the past century proved, that apparent destruction of matter was only a transmutation of form, so the physicists of the present century have proved that apparent destruction of motion is also merely a transmutation of form, a change in the mode of motion; mass motion changed into molecular motion, which reveals itself as heat, light, or electricity, or, *vice versâ*, any of the latter forces into one another or into mass motion. Of this transformation the steam-engine and the modern dynamo are forcible illustrations.

The great Swedish chemist Berzelius, more than half a century ago, expressed similar views when he declared that the heat and light we see in an electric discharge, say, in a stroke of lightning, is not the electricity itself. He states most explicitly that the restoration of the electrical equilibrium, which when destroyed gives rise to what we call electrical phenomena, causes the evolution of sudden light and heat in the bodies through whose medium this restoration of equilibrium takes place, which light and heat then radiates and diffuses itself according to the ordinary well-known laws of radiation and convection.

Crookes, in order to explain the peculiar behaviour of electric discharges through his highly exhausted tubes, teaches the doctrine that our conception of three states of matters—solid, liquid, and gaseous—is incomplete; he says that there is a fourth condition, which he calls radiant matter. He teaches as follows:

In solid bodies the atoms are in a state of rest—that is to say, as far as their relative position is concerned, but each atom oscillates to a greater or lesser degree. If the amplitude of the oscillation is small, we call the body cold; if the amplitude of the oscillation is large, we call the body hot, and, in so far, Crookes' theory agrees with what Tyndall has popularised in his well-known work, entitled "Heat as a Mode of Motion."

When the amplitude of the oscillations becomes so great that the atoms turn over and commence to rotate around their centres, the body reaches its melting point and becomes a liquid. Therefore, in liquids the atoms are not rigidly fixed to certain positions, but can freely roll over one another, and this constitutes the difference between solids and liquids.

When the velocity of the rotation becomes greater and greater, we say that the liquid is becoming hotter, and when from some cause or other this motion is still further increased, a new set of phenomena begins. The atoms are projected into space, and in place of rotating they are propelled from the liquid, and also repel one another, and as millions upon millions exist in the small space of a cubic inch, collisions take place by billions, and the body enters in what we call the "gaseous" condition.

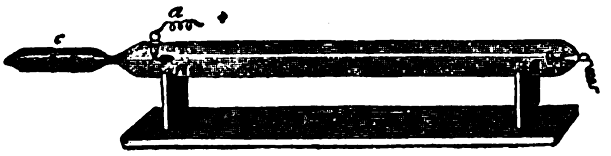

FIG. 1.

Here we have entered a field for the conception of which very few are prepared. We are as little prepared for it as our ancestors were when Galileo and Copernicus, and later, Herschel, revealed to mankind the immensity of the universe. When at school, studying astronomy, we obtained some kind of conception of the infinitely large.

We are not yet educated to the conception of the infinitely small, which is a new revelation, which is as difficult to grasp with our finite mind as it is to grasp the infinitely large. In considering the latter, we speak of distances so great that our common measures are utterly inadequate, and we must have recourse to larger standards of measures, such as the velocity of light connected with the time it takes to reach us from the most distant stars, which in some cases has been proved to be 10,000 years.

In considering the motion of the atoms of gaseous matter, we enter the other extreme of the conception of great and small. It appears that the number of atoms in one cubic inch of the common air we breathe is represented by a series of more than 20 figures, which particles or atoms are in constant continual collision to the number of ten million per second, while the velocity is so great that, if moving in a straight line, they would pass through a space

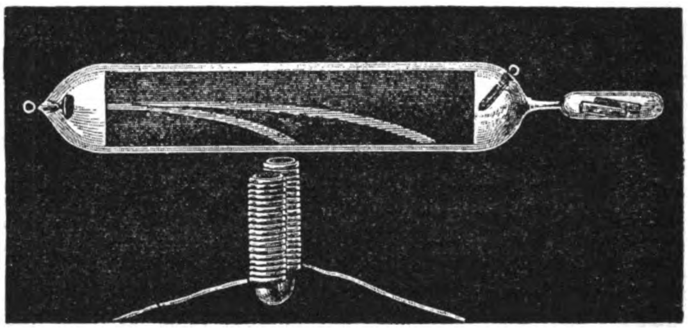

FIG. 2.

of 11,000ft. in a single second, thus surpassing the velocity of sound 10 times. This is the nature of the third or gaseous condition.

The fourth condition, attained by the Sprengel air-pump, is called by Crookes radiant matter. It is reached when the exhaustion proceeds so far that there are so few atoms left as to make the collisions exceptional; then the atoms will move in straight lines, and, encountering no mutual hindrance to their motion, they will follow the laws of electric repulsion and *radiate* from the point charged with electricity; hence matter in this condition is called "radiant matter."

Now we come to the most interesting feature of our consideration—namely, the chemical device referred to above, and intended to remove this last trace of air; recourse is had to the strong chemical affinity of potash for carbonic acid. The exhausted tube is filled with car-

Digitized by Google

bonic acid gas and again exhausted, and this process repeated in order to make sure that no atmospheric gas is left, but only very rarefied carbonic acid gas. A recess is connected with the tube during the operation, in which recess is placed a small stick of pure caustic potash. This recess is heated by a spirit lamp, so as to drive out the carbonic acid which the potash may contain, and then the vacuum is again made. The last remnant of carbonic acid which the air-pump cannot remove is then absorbed by the potash, when this is allowed to cool down. In this way the absolute vacuum is produced, through which no electric current can be made to pass. Of the accompanying two cuts, Fig. 1 represents an arrangement similar to the tube exhibited at the lecture, while Fig. 2 shows that as the direction of the magnetic needle may be deviated by a wire conducting an electric current, *vice versâ*, the direction of a flow of an electric current in a partial vacuum will be affected by magnetic influence, as shown by the results of charging and discharging the electromagnet seen below the tube.

The bearing of this fact is of the utmost importance in regard to our conception of the nature of electricity. It is generally admitted that the theory of the existence of a caloric fluid is erroneous, and that heat is merely a peculiar mode of motion, as referred to above, and this view is adopted, notwithstanding there is no experiment known serving to demonstrate that heat cannot be transmitted through a space absolutely devoid of all matter. Heat and light will both pass through a vacuum perfect enough to obstruct absolutely the passage of electricity. If there were such a thing as an electric fluid, it surely would pass through any empty space, and we are therefore driven to the conclusion that the presence of matter is as absolute a condition for the transmission of electricity as the presence of air is an absolute condition for the transmission of sound; and there is as little necessity to accept the hypothesis of the existence of an electric fluid as there is for the hypothesis of a sonorous or caloric fluid.

Air being the ordinary vehicle by which sonorous vibrations are transmitted, a proper degree of exhaustion will arrest this transmission, and any common air-pump can be made to prove that sound is with difficulty transmitted through a partial vacuum, and not at all when the vacuum is somewhat nearer to perfection. This experiment is acknowledged to be intended for a demonstration that the air molecules are the media for transmitting sound; that without such a medium there can be no sound, and that there exists no peculiar sonorous imponderable fluid which pervades the air, and should be the cause of sound transmission. When now we see that more highly rarefied air behaves toward electricity in exactly the same way as the lesser rarefied air behaves toward sound—namely, that at a certain degree of rarefaction the transmission becomes more imperfect, and at a certain point stops entirely—we are driven to the conclusion that electricity, as well as sound, is merely a peculiar form of motion of ponderable matter.

The conventional method of calling electricity a fluid must be understood to be only for the sake of convenience in explaining the phenomena presented. An argument in favour of this custom is that electric currents behave like water in two respects—namely, moving under greater or smaller pressure and in greater or smaller quantities.

What in water is called pressure or head is in electricity called E.M.F., and as hydraulic pressure can overcome great mechanical resistances, so E.M.F. overcomes great resistances.

It is measured by a standard unit, which is properly called after the illustrious Italian who first invented an apparatus which multiplied the small E.M.F. of a galvanic couple, the column of Volta. The quantity of electricity discharged through a channel is measured by another standard, also very appropriately named after the great French investigator Ampère, who discovered the laws governing the mutual action and reaction of current of great quantity.

That rarefied air is by no means so good a conductor as assumed by many is proved by the fact that it requires a considerable E.M.F. to pass it through. Machines producing static electricity, either by friction or induction, give that high E.M.F., while a single large galvanic cell, or, better still, a thermo-electric couple, offers the other extreme—viz., a large quantity of very low E.M.F., utterly incapable of being transmitted through any kind of vacuum.

I referred in the beginning of this paper to the application of the knowledge recently obtained in regard to the behaviour of electricity in rarefied air and in vacuo for the purpose of explaining certain natural phenomena. The phenomena are principally the aurora borealis and australis, and especially those which are related to the immense enigmas which from time to time appear in the heavens, the comets, which alarm the ignorant. On future occasion I hope to have the satisfaction to show you that all the peculiarities presented in both cases may be satisfactorily accounted for by the lately-discovered facts to which I have called your attention to-night.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts for the past week amounted to £4,164.

West Coast of America Telegraph Company.—A dividend of 6s. per share has been declared by the Directors of this Company for the current half-year, payable January 7.

Western and Brazilian Telegraph Company.—The traffic receipts for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Telegraph Company, were £3,464.

PROVISIONAL PATENTS, 1888.

December 21.

18,677. **An electric switch.** Lionel Beresford Bethell, Hill Farm, Morestead, near Winchester, Hampshire.

18,679. **A self-acting electric thermometer fire alarm, or temperature indicator, and atmospheric change indicator.** Lionel Beresford Bethell, Hill Farm, Morestead, near Winchester, Hampshire.

18,712. **Improvements in electric locks, bolts, and the like.** Charles Wells, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex.

18,715. **Improvements in or connected with telephones, speaking tubes, stethoscopes, phonographs, and other instruments through which sound waves pass.** Frederick John Smith, 23, Southampton-buildings, Middlesex. (Complete specification.)

18,718. **An improvement in tubular posts for telegraphic and other purposes.** Carl Ernst Julius May, 28, Southampton-buildings, Chancery-lane, London, W.C.

December 22.

18,727. **Improvements in electrical continuous current transformers.** Robert Percy Sellon and Charles Watson, 112, Belvedere-road, Lambeth, Surrey.

18,747. **An arc lamp regulator for electric lighting.** Henri Alexandre Gigaroff, 2, Wood-street Square.

18,754. **Improvements in or relating to galvanic batteries.** George Cecil Dymond, 6, Lord-street, Liverpool. (Carl Gassner, Germany.)

18,763. **Improvements in apparatus for detecting the presence and direction of currents of electricity.** Charles Barnard Burdon, 3, Kimberley-street, Princes Park, Liverpool, Lancashire.

18,784. **Method of and means for regulating electric currents, dynamo machines, and electric motors.** Wilhelm Friedrich Lahmeyer, 433, Strand, London.

18,790. **Improved electrical signalling apparatus.** Sigmund Schuckert, 53, Chancery-lane.

December 24.

18,807. **Improvements in the method of and means for producing intermittent electric currents.** Thomas Parker 70, Market-street, Manchester.

18,812. **Improved method and apparatus for the distribution of electricity by means of alternating currents of electricity in conjunction with electrical storage.** Reginald Frederick Yorke, The Oaks, Haywards Heath, Sussex.

18,832. **An electric miners' safety hand lamp which may be used for domestic and other purposes.** Edward Thomas Boston, Elm View, Arundel-road, Weston-super-Mare, Somersetshire.

18,854. **Improvements in electrical switches.** Henry William Short, 53, Chancery-lane, London.

Digitized by Google

18,856. **Improvements in printing telegraphs.** George Valentine Sheffield and Moses Lowenstein, 53, Chancery-lane, London.

18,858. **Improvements in electro-chemical generators.** Frederick John Brougham, 46, Lincoln's-inn-fields, London. (La Société Perreur-Lloyd and fils, France.)

DECEMBER 27.

18,881. **Improvements in the preparation of materials which have to be submitted either to voltaic heat or to electric heating, combined with electrolysis.** Louis Reuleaux, 46, Lincoln's-inn-fields, London.

18,900. **Improvements in electric telegraphy.** Mark Wesley Dewey, 45, Southampton-buildings, London. (Complete specification.)

18,908. **Improvements in electric arc lamps.** George Ben Goodfellow and Patrick James Charles, 70, Market-street, Manchester.

18,911. **An improvement in dynamo-electric machines.** Benjamin Hillier Antill and Edward Friedrich Hermann Heinrich Lauckert, 28, Southampton-buildings, Chancery-lane, London. W.C.

DECEMBER 28.

18,922. **Improvements in electrical switches.** Thomas Wardell, 87, St. Vincent-street, Glasgow.

18,930. **An electric automatic work detector and recorder.** Joseph Blamires and William Blamires, Phœnix Mills, Leeds-road, Huddersfield.

18,966. **Improvements in or connected with telegraphic transmitters.** Julius Timm, 77, Chancery-lane, London, W.C.

18,968. **Improvements in and relating to electric primers or igniters for blasting or firing mines, torpodoes, projectiles, guns, and the like.** Edmund Louis Zalinski and Henry Julius Smith, 77, Chancery-lane, London, W.C.

DECEMBER 29.

18,991. **A bent plate storage battery.** Matthew Doubleday, 81, Carrington-street Bridge, Nottingham, and Thomas William Bush, Willey Old Hall, Willey Park, Broseley, Shropshire.

18,994. **Improvements in and appertaining to the manufacture of metals or metallic alloys by means of electricity.** George Cecil Dymond, 6, Lord-street, Liverpool. (Jean Marie Anatole Gérard Léscuyer, France.)

DECEMBER 31.

19,034. **Improvements in secondary voltaic batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

19,045. **Improvements in magnet call bells.** Thomas John Handford, 50, Bedford-row, London, W.C. (The Western Electric Co., United States.)

19,049. **Improvements in electrical firing keys.** Frederik Vilhelm Andersen, 3, Elm-court, Temple, E.C.

19,058. **Improvements in electric batteries.** James Yate Johnson, 47, Lincoln's-inn-fields, Middlesex. (Fernand Gendron, France.)

19,061. **An improvement in materials to be used in galvanic batteries.** Alice Cornwell, 24, Southampton-buildings, London, W.C.

19,066. **A new or improved secondary clock.** James Grieve Lorrain, Norfolk House, Victoria Embankment, London, W.C.

19,067. **A new or improved secondary clock.** James Grieve Lorrain, Norfolk House, Victoria Embankment, London, W.C.

19,068. **A new or improved method of and apparatus for storing energy in small mechanical accumulators.** James Grieve Lorrain, Norfolk House, Victoria Embankment, London, W.C.

19,069. **A new or improved method of and apparatus for storing energy in small mechanical accumulators.** James Grieve Lorrain, Norfolk House, Victoria Embankment, London, W.C.

19,070. **Improvement in electric arc lights.** Charles Wells, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex.

COMPLETE SPECIFICATIONS ACCEPTED.

DECEMBER 29, 1887.

17,902. **Improvements in apparatus for telephone exchanges.** Sydney Pitt, 24, Southampton-buildings, London, W.C. (Charles Ezra Scribner, United States.)

JANUARY 2, 1888.

56. **Improvements in the manufacture of the incandescing portion or luminant of incandescence electric lamps.** James Yate Johnson, 47, Lincoln's-inn-fields, Middlesex. (Theodore Mace, United States.)

JANUARY 12, 1888.

531. **Improvements in and means or apparatus for and connected with the generation, distribution, measurement, and control of electricity.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

FEBRUARY 20, 1888.

2525. **Improvements in arc electric lamps.** Charles Richardson 46, Leopold-street, Weaste, near Manchester.

FEBRUARY 21, 1888.

2586. **Improvements in and relating to incandescent electric lamps.** Rankin Kennedy, 96, Buchanan-street, Glasgow.

FEBRUARY 23, 1888.

2698. **Improvements in the construction of sanitary and magnetic mattresses.** Edward Parker Dove, Sunbridge Chambers, Bradford, Yorkshire.

FEBRUARY 24, 1888.

2784. **A method of and apparatus for electrically lighting railway and other carriages.** John Imray, 28, Southampton-buildings, Chancery-lane, London, W.C. (Robert Imray, S. Australia.)

2785. **Improvements in holders for electric glow lamps.** Edward Frederick Hermann Heinrich Lauckert, 28, Southampton-buildings, Chancery-lane, London, W.C.

2794. **Improvements in electrical firing keys or contact makers.** Charles Ambrose McEvoy, The London Ordnance Works, Bear-lane, Southwark, Surrey.

FEBRUARY 29, 1888.

3071. **Improvements in miner's safety lamp.** John Pearson, 3, Quality-court, London.

JUNE 13, 1888.

8700. **Improvements in and relating to electric batteries.** Louis Marie Joseph Charles Clement Renard, 23, Southampton-buildings, London.

AUGUST 18, 1888.

11,941. **A new non-magnetic metallic alloy.** Heinrich Ostermann and Charles Lacroix, 68, Fleet-street, London. (Date applied for under Section 103 of the Patents, &c., Act, 1883, 25th April, 1888.)

NOVEMBER 14, 1888.

16,556. **Improvements in apparatus for adjusting the electric or other light in projecting lanterns.** Herbert Charles Newton, 6, Bream's-buildings, Chancery-lane.

SPECIFICATIONS PUBLISHED.

During the week ending 22nd December, 1888.

1887.

17,726. **Electromotors.** J. G. Statter. 6d.

1888.

1213. **Applying electricity to spectacle frames.** J. T. Leighton. 8d.

1383. **Electromotor or electric current meter.** F. Borel and E. Paccaud. 11d.

11,065. **Electric lamps.** W. P. Thompson. (Westinghouse.) 6d.

11,681. **Electric batteries.** C. E. Liebert and S. A. Rosenthal. 6d.

15,388. **Regulating dynamo-electric machines.** A. Shippey. (Waterhouse.) 8d.

15,612. **Insulators for electrical conductors.** J. C. Love. 8d.

During the week ending 29th December, 1888.

1887.

5880. **Weighing machines and dynamo meters.** (Reprint with alterations.) H. Knight. 2s. 4d.

17,138. **Generating and converting electric currents.** R. H. Courtenay. 8d.

17,415. **Electrical measuring and recording apparatus.** L. G Lorrain. 8d.

17,966. **Electric batteries, &c.** O. Y. Rhodes. 8d.

1888.

1875. **Dynamo-electric machines, &c.** G. Hookham and R. H. Housman. 8d.

1891. **Flexible battery cell, &c.** M. Bailey and J. Warner. 8d.

3312. **Voltaic batteries.** E. Tyer. 8d.

14,984. **Rotating hydro-extractors by electricity, &c.** R. R. Hutchinson. 8d.

16,146. **Electro-medical batteries.** F. Moreton. 8d.

NOTES.

Meiringen.—The village of Meiringen, in the Bernese Oberland, is to be lighted entirely by electric light.

O.S.A. Paper.—Mr. Snell reads his paper on "Electro-motors" next Wednesday at the Central, at 7.45 p.m. Visitors may attend.

Metz.—The German Government have established extensive electric lighting plants for the barracks and fortifications, including search lights and portable plants.

Telegraph to China.—The arrival is announced at Warsaw of several French engineers who are to extend the telegraph line between Russia and China, *viâ* Siberia.

Reading.—It is expected that the electric light installation at Reading, now being completed by Messrs. Laing, Wharton, and Down, will be ready for lighting some of the streets in a few days.

Alternate Motors and Meters.—With reference to alternate motors Mr. Ferranti writes to us that he is not the owner of a motor; what he has bought is a Swiss meter, details of which may be published shortly.

The St. James' Station.—Work is rapidly progressing at the St. James' central station; two of the large boilers are already down, and other machinery is being added. The station will probably be ready for work in six weeks' time.

Royal Meteorological Society.—The annual general meeting will take place at 25, Great George-street, Westminster, on Wednesday next at 7.15 p.m., when the president, Dr. W. Marcet, F.R.S., will deliver his address on "Fogs," illustrated by lantern slides.

Birmingham.—The Birmingham Council are understood to be considering whether they shall not themselves apply for powers to light the town, instead of allowing the concession to go to a private firm, and so reduce the profits of the gas department, which in that town is owned by the municipality.

France.—Montluçon (Allier) has a central station with 400 lamps. Valleraugе (Gard) will shortly have a central station for 500 lamps, supplied from a turbine half a mile away. The town contains important silk spinning mills, and these will be supplied night and day, besides 25 lamps for the public streets.

Writing on Rose Leaves.—The passage of a current of electricity through a rose leaf is found to take out the colour, leaving a white mark. This effect has been prettily used at a fashionable dinner, where the lady of the house had the place of each guest indicated by a rose, on the petals of which the name was thus delicately inscribed.

Berlin.—Besides the two large central stations in Berlin, the third, which is now to be established, brings the total up to a supply of 200,000 lamps, requiring 18,000 h.p., representing about one quarter of the total number of gas jets in Berlin. Steam-engines of 1,000 h.p. will be employed, instead of those of 380 h.p. as hitherto installed, for facility of supervision.

Electrical Steam Explosive.—Mr. Samuel Joyce, jun., of Richmond-road, Dalston, proposes to use a new form of blast for mining, in which the explosive force of steam is utilised. The steam is generated from water enclosed in an air-tight compartment by a wire heated by the passage of an electric current. The contacts are enclosed in an air-tight box.

Geneva.—*L'Electricité* for December 29 contains descriptions and illustrations of the plant in use at the Geneva lighting station, consisting of Picard turbines coupled direct to Thury dynamos. The mains are underground, laid by Messrs. Siemens and Halske, and plans of the district are given, together with details of the switchboards used at the installation.

Electric Boxes.—The Electric Automatic Delivery Box Company has been reorganised, and is expected at last to make electric boxes. A small amount of £20,000 has been knocked off the price of payment to vendors of the patents, but even for £10,000 *we* should like an order for electric boxes, and would make any amount of them at a price allowing "20 per cent. profit."

Lectures on the Calculus.—A special course of twelve lectures, with exercise work, will be given by Prof. Perry, F.R.S., at the Finsbury Technical College, on the differential calculus. The course will be arranged to give a working knowledge of the subject to electrical and mechanical engineers who have only an elementary knowledge of algebra and trigonometry. The first lecture will be given on the 15th inst.

Anti-Friction Packings.—We have received from Messrs. D. G. Cresswell and Son, of Barkerend-road, Bradford, their catalogue of anti-friction packing for engines—a packing needing no oil or tallow, and very lasting in its qualities. They also manufacture various asbestos compounds, sheeting, joints, washers, and cloth, with an asbestos anti-corrosive cement for use for making steam joints on pipes and boilers.

Electrical Warfare.—Frank R. Stockton, author of "The Lady or the Tiger," is writing a romance in the American *Once a Week*, setting forth a supposed war between England and the United States, in which the American Government adopt the idea of letting out the contract to a war syndicate who construct all sorts of electric engines, torpedoes, signals *et hoc genus omnes*, and speedily knock the mother country into fits.

Annual Supper.—On the last Saturday of the old year the annual supper of Messrs. Laing, Wharton, and Down's employés took place at the Queen's Arms Hotel, Queen-street, E.C. Mr. D. C. Bate, the firm's engineer, took the chair, and after ample justice had been done to the excellent catering of the landlord, the usual loyal and patriotic toasts honoured, and continued success to the firm drunk with three times three and one cheer more, a most enjoyable evening was brought to a close by some excellent song-singing, to the accompaniment of a piano presided over by Mr. J. Sugden, a member of Messrs. Laing Wharton, and Down's staff.

Armstrong's Lock Nuts.—The Walsall Electrical Company manufacture a new lock nut (Armstrong's patent) suitable for shafting, gearing, foundations, etc., and other places where nuts may work loose from vibration. The top of the bolt is octagonal, slightly smaller than the screw; when the nut is screwed up, a cup fitting this octagonal part is slipped over and fits on top of the nut in any position from an eighth of a turn. A split pin keeps this in position, and of course effectually prevents the nut from turning or getting loose, and also acts as a protective cap against rusting or corrosion. When the cap is applied the

Digitized by Google

whole is as rigid as a rivet, and neither threads, bolt, or nut are disturbed or injured.

Transmission of Power.—One of the largest plants in the United Kingdom for transmission of power by electricity is likely soon to be practically carried out. This is for a large paper mill, situated near a river where a fall of water estimated to give a theoretic value of some 700 h.p. is available. Experiments are now being undertaken to determine what is the actual force, and a thousand pounds or so is being expended on sluice-gates for this purpose. The contract—which is arranged subject to the result of these tests—will stipulate that not less than half the theoretic value, including all losses, will be delivered at the further end, a distance of 3½ miles, so that at least 350 h.p. will be transmitted. Every engineer, electrical or otherwise, will be interested in the result of this undertaking.

City Lighting.—On Tuesday, at the meeting of the City Commission of Sewers, the chairman, Mr. W. H. Pannell, replying to Mr. Thompson, said the question of inviting tenders for the supply of the electric light to the City was still before the engineer, the solicitor, and Mr. W. H. Preece, F.R.S., who were framing the conditions under which tenders should be asked. He hoped their report would be before the committee at their next meeting, but until the arrangements were finally completed, no tenders would be invited. Mr. Baylis, the solicitor, in answer to Mr. Rose-Innes, said it would be usual, in the event of any applications by companies for provisional orders to light the city by electricity, for the Commission of Sewers to oppose them in order formally to obtain a *locus standi* when the schemes came before the Parliamentary Committee.

Electrical Architects.—A writer in the *Builder* suggests that, in view of the probability of great extension of electric lighting in the immediate future, instruction in the principles of the use of electricity should be given by the Royal Institute of British Architects and the Architectural Association. The editor "quite agrees that practical electricity is a subject which the architect of the future will have to study, and that it ought to form part of an architectural student's curriculum." A subscription to a technical paper, a visit to one or two good electric light installations, and a few conversations with a practical electrical engineer would be useful, in this present time, to a great many practising architects, who will shortly have to deal with the problems of electricity, specially of electric light, but also, in all probability, in many other domestic electric applications in modern houses.

Protest at St. James's.—A meeting of the residents of Pall-mall and St. James's-square, held at Willis's Rooms the other day, passed the following resolution: "That this meeting is of opinion that the installation and erection of a central station for electric lighting for the parish in the immediate neighbourhood of Pall-mall and St. James's-square is calculated to injure the commercial and residential value of property in the neighbourhood, and is quite unnecessary in view of facilities for bringing the current from distant localities more suited for the purpose." Mr. Foster, who stated that he was interested in the St. James's Electric Lighting Company, opposed the motion, contending that the works would be a boon to the neighbourhood. Mr. J. T. Musgrave also thought that the electric works would not create any nuisance, as smokeless coal was to be consumed, and the company would consume their own smoke. The resolution was carried by 19 to 11.

Electric Engraving Pen.—We have been shown an ingenious pen for use by engravers, invented by Mr. Boyle, in which the engraving is done by electricity instead of by a graver or by acid. The action is practically to cause a series of small arcs to burn away the metal to a greater or less depth as desired, to form an engraved plate. An armature capable of very rapid vibrations is mounted in the form of a pen, and has a rod with a platinum tip connected to it, projecting slightly through a glass point. One wire from a battery is connected to the plate which is to be engraved, and the other to the terminal of the pen. On touching the plate and tracing out a design, or lettering, the platinum point vibrates up and down, and the small arcs which form at the point of contact burn away the metal and engrave the plate to a greater or less depth according to the quickness of motion. The plate thus engraved can be used at once for printing. We understand a large number of pens have been ordered by engravers and others. The sole right of manufacture has been assigned to the Electrical Apparatus Company, of 4, Charing Cross.

Journal of the Old Students' Association.—The *Journal* of the City Guilds Old Students' Association assumes a new phase, and will be devoted to the interests of past and present students of the Finsbury and Central Institutes. It is at present intended to publish six numbers per session, and to commence and end the *Journal* volume with the annual session of the colleges. While the *Journal* will naturally be chiefly concerned with scientific and literary matters, more prominence than hitherto will be given to the social aspects of college and O.S.A. life. The committee appeal to every student, past and present, to give all the assistance possible, either by becoming subscribers, or by sending or procuring contributions for publication. Several old students who have received appointments in the provinces and abroad have promised to send accounts of their travels and experiences, and these, no doubt, will form an interesting feature of the new volume. A register of situations wanted is kept in conjunction with the O.S.A.; communications about these should be addressed to the president of Old Students Association, Mr. Thomas Adams, 25, Maitland-park-road, N.W.

Derby Central Station.—The nucleus of a central electric light station is being put down at Derby by Messrs. John Davis and Son, of All Saints' Works. The plant, in the first instance, is for 500 10 c.p. lamps, and will comprise accumulators which will ensure a steady supply. The current will be on till 9 p.m., or later by special arrangement, and the charges are on the basis either of from dusk to eight, or from dusk to nine, on a sliding scale according to the candle-power, as follows:

	Incandescent Lamps.	
C.p.	Dusk to 8 p.m.	Dusk to 9 p.m.
10	£1 5 0	£1 15 0
20	2 0 0	2 15 0
32	3 10 0	5 0 0
150	8 10 0	11 10 0
200	10 10 0	14 10 0
300	12 10 0	16 0 0
500	20 0 0	30 0 0
	Arc Lamps.	
400—500	14 14 0	18 18 0
1,000	18 0 0	24 0 0
1,500	25 0 0	35 0 0

These prices include carbons and attendance for arc lamps.

Digitized by Google

The current will be supplied through the day in foggy weather when light is necessary, but not on Sundays. A guaranteed minimum rental of £5 per annum is required.

Polar Investigation.—The report of the Norwegian party of the International Polar Investigation, says *Nature*, contains the results of the observations which were made according to the programme decided upon at the Polar Conference at St. Petersburg, in August, 1881. The observations were made at Bossekop, in Alten, in lat. 69deg. 58min. N. and long. 23deg. 15min. E. of Greenwich. The first volume, issued in 1887, contains the astronomical and meteorological observations, and the second volume (Christiania, 1888) gives the results of the magnetic determinations and observations of auroræ. In the meteorological section, tables are given of the hourly readings of the temperature and humidity of the air, height of barometer, direction of winds and nature of clouds, extending from August, 1882, to August, 1883, inclusive, and concluding with monthly averages. In vol. ii. are given the records of the determinations of the magnetic declination and horizontal and vertical intensity. These were made fortnightly during the year, at intervals of five minutes during the day, so that the carefully-executed curves expressing the results of the observations are very detailed and convenient for comparison with the complete descriptions of auroral displays, the records of which are also contained in this volume. No doubt these results will be of great service in correlating auroræ with magnetic disturbances.

Telephone Extension.—A writer in the *Western Morning News* mention a method to persuade people who know nothing about telephones to join. In the United States, especially out West, they adopt the plan of fixing an electric bell for five dollars a year in the house of anyone who thinks he should like a telephone, but is not sure about it; and then when the bell rings the man puts on his hat and walks down to the office, and talks to the person who has rung him up, paying five or ten cents for the talk. In a few weeks the man finds it such a nuisance to have to walk to the office every time, that he calls upon the company to fix him up a telephone, and so becomes a subscriber. Most of the storekeepers in Dixon, 90 miles from San Francisco, where an exchange has just been opened, have only a bell and no telephone; but they can at any time, by walking down to the office, talk to San Francisco, or Sacramento, or any other town in California, and any person in these towns can ask the agent at Dixon to ring up any of the Dixon subscribers. The writer suggests that if any town or village within 50 miles of the nearest large town had a wire connecting it therewith, and a few electric bells to begin with, to the principal residents or shopkeepers, the value of the telephone would be better appreciated. In England the telephone is regarded as a luxury; in America it is deemed a necessity. The suggestion is worthy of consideration by the telephone companies desiring further subscribers.

Electricity v. Gas.—The gas journals are at last beginning to wake up. The annual review has come round, and things are not quite so bright as they could wish. There is a big struggle in front of them, and the sooner they know and acknowledge it the better. Says the *Gas and Water Review:* "We should like to be able to chronicle a greater increase in the sale of gas, but it is no good blinking the matter. If it were not for the application of gas to heating and cooking purposes, and to its rapid advance as a motive power, the suppliers would have a poor result to show. It is a fact not to be denied that the electric light is steadily gaining ground, and we regret that contemporary journals should be so blind to the interests of the great industry whose welfare they are supposed to watch, as to throw ridicule upon the advances of electric lighting. It is mainly due to the want of forethought of the conductors of the *Gas Journal*, and those associated with them, that gas suppliers opposed the Electric Lighting Bill in 1882; they should have endeavoured to have secured powers for gas companies to supply electric lighting, as is now being done largely throughout the United States of America. It is certain that Parliament will not now grant such powers to gas suppliers, and they must extend their efforts in other directions. Let them canvass their districts, and induce consumers to heat by gas, cook by gas, and have gas-engines fixed wherever power is needed. The time has most assuredly passed by when gas consumers will come cap in hand to the gas companies, and then have to accept their irksome and arbitrary regulations. It is not sufficient that gas is cheap; the business must be sought for, or others will secure it."

Electric Sugar Swindle.—On Friday the sweet hopes of the electric sugar investors were ruthlessly dashed by receipt of a telegram mentioning "Grave doubts developed, process not what claimed, doubts fully confirmed, obtained access to upper floor, satisfied the sugar manipulated from refined." The shares fell at once from £117 to 25s. The wonder is that the grave doubts were not sufficiently developed before; the fact that the denial of access to the upper floor was so long complied with, and the belief in the process by those unacquainted with electrical science so fervid, is another instance of the gullibility of the public. This belief was fully shared by several financial papers, and the "Electric Sugar Bubble" will probably rank in financial history amongst the most notorious swindles of the time. Dr. Silvanus P. Thompson writes to the *Times* as follows: "Sir,—In October last you did me the favour of inserting a letter in which I sounded a warning note to the too-confiding investor, pointing out that so far not one shred of proof had been forthcoming that electricity had anything whatever to do with the so-called process for the 'electric' refining of sugar. Nor was I alone in my disclaimer; for in all the technical electrical journals similar warnings as to the true nature of this alleged process were given in guarded, but unmistakable terms. Unfortunately, it would seem that would-be investors prefer the opinions of every other sort of adviser to that of those persons who have made the study of electricity and its powers their life-long pursuit. The result is that whereas a week ago they were clamouring for the privilege of buying up the shares at 300 per cent. premium, they now learn on unmistakable authority from your Philadelphia correspondent that the whole thing was a shameless swindle. They now know that the name 'electric was a mere cover for a vulgar cheat, in which previously refined and crystalised sugar was surreptitiously conveyed to the factory and substituted, behind locked doors, for the unrefined article. This is not the first swindle in which the word 'electric' has been skilfully used by the knave to dupe the fool; nor, I fear, will it be the last." The latest telegrams state: "Warrants issued, parties fled to Canada."

Thomson-Houston Catalogue.—An advance copy has reached us of what is a really handsome, complete, and

Digitized by Google

tasteful catalogue, to be issued by Messrs. Laing, Wharton, and Down, of the Thomson-Houston Company's electric apparatus. It is a catalogue such as we do not often see got up by English firms (although we could no doubt produce them if the price were paid), and it very forcibly illustrates the progress of the Thomson-Houston system in the last few years. We see first a small country factory, as in 1882, and a gigantic concern at Lynn, Massachusetts, as in 1888, consisting of six large and handsome blocks of buildings, all of which are as busy as possibly they can be in turning out arc and incandescent dynamos and Thomson-Houston motors. A further building is shown—the carbon factory—where specially tested carbons are made for the various supply companies. In the catalogue, beautifully engraved and delicately printed cuts show the arc lamps, of all types, for houses, streets, projectors for posts and wall brackets, and incandescent lamps for long distance series lighting, with incandescent dynamos. The T.H. compensator system is used for greater distances than 2,000ft.; this is not a transformer, but a simple arrangement of coils to maintain perfect regulation of the current which may occur at the distributing centre. The Thomson-Houston transformer system is illustrated, with alternating dynamos and exciters, either together or separately run, with transformers, waterproof in construction, cased in, and capable of being hung outside in any convenient position. The Thomson-Houston motor comes in for a fair share of attention. Some idea of the extent of the growth of the system may be gathered from the figures given at the end of this catalogue, which show that up to the 1st January, 1889, 435 arc light companies have been established, supplying some 52,000 arc lights in America; and 175 incandescent companies, supplying 97,000 incandescent lamps. Plans of various Thomson-Houston stations are given, of from 100 to 1,000 h.p., and altogether the issue of the catalogue is one of the best illustrations of the enterprise of the promoters of this system that could be seen.

Woodhouse and Rawson Catalogue.—The new Woodhouse and Rawson, Limited, catalogue, compiled by Mr. Rentell, has just been issued. It is a neat and handy book of some 200 pages, describing almost every electrical requisite conceivably required for electrical contractors, ranging over the list of engines, dynamos, lamps, and all and sundry fittings, with other materials necessary to the working of electric installations and other electric applications. The scheme of the company has been to place themselves in a position of central supply, so that even where they do not manufacture themselves, special terms are arranged with other makers, so that a customer can obtain on equally good terms all they require without opening new accounts. A number of tables, with other interesting information, are given, and the perusal and study of the catalogue will give a very fair idea of the present state of electrical industry. With reference to their own manufactures, the incandescent lamps may be specially mentioned. For some time the Woodhouse and Rawson Company have been busy supplying "unflashed" lamps, before-times stopped from legal difficulties. In their new catalogue these lamps find an important place. An entirely new type of carbon has been produced, of such a hard and dense nature that good filaments are made without flashing, and, of course, are thus homogeneous in substance throughout. Special attention is paid to marking the voltage of lamps, so that, whether of greater or less candle-power, the brilliancy or degree of incandescence shall be the same in all lamps. The charges in the filament have enabled shorter filaments to be used, thus better resisting breakage from vibration. Messrs. Woodhouse and Rawson have settled their normal efficiency of lamps at 3·5 watts per candle-power, with an average life of over a 1,000 hours, comparing favourably with other makers, and where it is more economical to run higher lamps, are marked at an efficiency of 2·75 watts per candle, with a slightly increased cost for renewals. Special attention is given to lamps for primary battery lighting. Their noted hair filament lamps for surgical and dental purposes, theatrical effects, electric jewellery are constructed for extra high efficiency for small lamps. A speciality is made of silvered lamps. Standard lamps for ordinary use are made of 8, 10, 16, 20, 50, and 100 c.p. A large number of testimonials from private and public individuals, and from various publications, are given to testify to the excellence and efficiency of the Woodhouse and Rawson lamps.

Standards of Light.—The *Journal* of the Society of Arts for 21st December contains a paper on "Standards of Light," read by Mr. W. J. Dibdin, F.C.S., in which he sets forth the variations and vagaries of standard candles, and incidentally mentions, in regard to manner of burning standard candles, that in the Gas Works' Clauses Acts, 1871, it is specifically laid down that "the tip of the wicks shall be glowing and slightly bent," and thus a distinct condition is introduced. Mr. Dibdin recommends a modified form of the "ten candle test," which he has called the "Pentane Argand," as a most reliable standard, free from all objection from the "height of the flame" point of view, independent of coal-gas and atmospheric influences, such as temperature or pressure; possessed of the advantage of being a decimal factor—viz., ten candles; and furthermore being a desirable unit to use in coal-gas testing during foggy weather, as the distance of the opposing lights from the photometer disc is for that purpose practically equal. The arrangement possessed of these advantages is very simple, no meter, governor, or other measuring or controlling adjunct, beyond a simple tap, being necessary. It is merely a small argand burner suited for burning gas-air. Supported 2·3in. above the steatite burner is a screen to cut off the light emitted from the top of the flame, and indicating rods to assist in regulating the flame to a height of three inches. The standard combustible is the vapour of pentane; this is driven forward to the burner by a current of air from a holder or pressure bag, as may be convenient, about half a cubic foot of air per hour being required. The pentane is contained in a carburetter precisely similar to that of Mr. Methven's, and the air carburetted with the pentane in the same way that he carburetts the coal-gas for his later form of standard. A variation in the temperature of the carburetter makes no difference, as the same result is obtained when the trough of the carburetter is filled with water at 90deg. F., and then with ice and water. The flame should be adjusted to a height of 3in. for uniformity, but if from accident the flame falls to two and a half inches or rises to over four inches, no difference is observable in the volume of light emitted under the screen. This remarkable result is ascribed to a compensating action in the blue portion of the flame, which is reduced in size when the luminous portion is lowered, and contracted in bulk, and thus causes a greater length of the white flame to be seen under the screen, and

Digitized by Google

inversely, when the flame is raised and expanded in width, the blue portion is also increased, and thus compensates for the otherwise greater intensity of the white portion. Mr. Dibdin hopes that it may form a neutral ground on which, for a time at least, conflicting interests may meet to their mutual advantage.

Proposed Electrical and Industrial Exhibition. A syndicate of commercial gentlemen in Birmingham, says the *Birmingham Daily Post*, are taking active steps to promote an electrical and industrial exhibition on a very extensive scale in Bingley Hall during the months of August, September, and October next. Private circulars have been sent to a large number of traders and others likely to be interested in such a movement, and the result so far has been of a satisfactory character. A long and influential list of patrons—gentlemen well known in scientific, commercial, and social circles—has been secured, and the names of some eminent firms are mentioned as being likely to send exhibits. These will be divided into two portions—electrical and industrial. The former, according to the prospectus of the promoters, is to include a "complete display of electric lighting, with arc and incandescent lamps, upon every known system and combination, working in series, in parallel, direct and through transformers of various types; lamps of from one to 25,000 c.p.; all systems for electric transmission of power, electrical motive power to be used for all working exhibits, electric motors on all systems, electric energy applied to all possible industrial purposes, electric welding, electric smelting, electrotyping, deposition, telpherage working, etc., etc.; electric lighting and motive power for coal mines, with a model coal mine in actual work; electric telegraphy, signalling, telephones, bells, clocks, instruments, etc.; electricity as applied to medical and surgical purposes, and to marine engineering; exhibits of dynamos, battery appliances, instruments, and all novelties in electrical engineering; steam, gas, petroleum, and other engines." It will be seen from this epitome of exhibits that the electrical portion alone offers plenty of scope for a very interesting and attractive display. The coal mine is to be built of coal and to be worked by colliers. Birmingham trades, it is hoped, will be well represented in the industrial department, where stalls are to be set apart for manufacturers of pens, watches, bicycles, nails and rivets, screws and bolts, gas and electrical fittings, jewellery, machinery for electroplating, chemical trades, opticians, and any other industry or any speciality that may be desired. Of course, the public will be admitted on payment, and in the case of any profits being realised from the enterprise they will be divided between the General, the Queen's, and the Jaffray Hospitals. A guarantee fund has been set apart to meet any loss in the event of a deficiency, which is looked upon as very improbable on account of the attractions that will be offered. At the present time many of the details are not decided upon, but steps will be taken to popularise the exhibition by bands and other forms of entertainment; and it is stated that an attempt will be made to induce his Royal Highness the Prince of Wales to perform the opening ceremony.

The Cowles Process.—At the last meeting of the Cleveland Institution of Engineers, at Middlesbrough, a paper was read by Mr. William Boby, of London, on the Cowles process of production of aluminium, showing the value of the addition of small quantities of aluminium to iron and steel in the course of manufacture. After describing the Cowles furnace at Milton, which has already been fully described in this paper, Mr. Boby said that the greatest field of usefulness for aluminium was for mixture with cast steel. When the amount of concentration exceeded a certain amount the alloy became non-magnetic, and this was a property which might possibly be found to be of practical value. Another good property of aluminium, as produced by the process, was the quality of equal diffusion. A ladleful of molten steel would be impregnated with a minute proportion of aluminium if a small quantity of the broken-up alloy were placed in the bottom of it before the steel were poured in. The use of ferro-aluminium, said Mr. Boby, had not, up to the present, obtained any large dimensions in this country, but in the United States it was already largely employed. The effect of the alloy upon steel was to raise its elastic limit and ultimate strength, while it lowered its melting point, and facilitated the making of sound castings, the last-named point being one of great importance. This alloy was employed by the makers of "Mitis" castings in America, who obtained it from the Cowles Company, at Lockport. Mr. Boby's partner, when spending a few days there some months back, saw an order come in for 10 tons, and when it was borne in mind that one-tenth of one per cent. of aluminium was an ordinary proportion to add to steel castings it would be seen that this represented operations of some magnitude. The effect of ferro-aluminium upon puddled bar iron had been investigated by a member of the firm of P. and W. Maclellan, Glasgow, with most satisfactory results, the tensile strength being raised to 31 tons with 22 per cent. elongation, while the quality was equal to that of the finest mild steel. Mr. W. J. Keep, of the Michigan Stove Company, U.S.A., one of the largest stove-making concerns in the States, bore testimony to remarkably beneficial effects of ferro-aluminium as applied to cast-iron. English firms were commencing to use this alloy, and no doubt its employment would rapidly extend. Some of the best-known steelfounders were using it in England. With aluminium-bronze the breaking strain had been raised to 50 tons per square inch, and even with a test bar to nearly 60 tons. Aluminium-brass possessed, perhaps, the most surprising qualities of any of these alloys. To the ordinary constituents of brass 3½ per cent. addition of aluminium produced the astonishing result of 95,000lb. tensile strength, with a transverse strength of 72cwt. on a bar 1in. square and 12in. between supports. Both the bronze and the brass were unaffected by salt water, and promised to be extensively useful for many parts of machinery. In reply to questions as to other productions, practical details, and as to whether the Cowles Company had tried the electric welding, Mr. Boby said some small quantities of silicon-bronze had been made, but they had not pushed the sale, as the furnaces were fully occupied otherwise. Silicon-bronze was, however, used in the States for telephone wires, and was extremely strong. The Cowles Company had never produced pure aluminium in this furnace commercially. They say they could make it if the market required it. He could not say how the carbons were produced, but each lasted three days of 24 hours each. Electric welding had not been tried by the Cowles Company in this country. Mr. Wood, in proposing thanks, remarked that he had been told of orders for aluminium alloy from 50 different places in the neighbourhood of Cleveland recently, which went to show that the use was rapidly extending in this country.

THE TELEPHONE IN THE WEST OF ENGLAND AND SOUTH WALES.

It is as well that Nature's law "like father like son" does not always hold good in matters commercial, else would the history of telephonic enterprise in this country prove very indifferent reading. As it is, we have not much to be proud of when we compare ourselves with other nations, and what little progress has been made in the adoption of the telephone must be sought for principally in the minor cities of these islands.

History of the Western Counties Company.

A very lively and promising offshoot of the United Telephone Company has its headquarters at Bristol, and as we recently had the opportunity of paying a visit to its central exchange, we propose to give a sketch of the rise and progress of the "Western Counties and South Wales Telephone Company, Limited." This company was registered in December, 1884, with a capital of £400,000, of which £100,000 was in preference shares, 20,000 of £5 each, bearing a cumulative dividend of 6 per cent., and 300,000 fully-paid ordinary shares of £1 each. The district within which this company is licensed to work by the United Company and the Postmaster-General is an extensive one, and comprises the counties of Cornwall, Devon, Somerset, Dorset, Hants (including the Isle of Wight), Wilts, Gloucester, Hereford, Monmouth, Glamorgan, Carmarthen, Pembroke, Cardigan, Brecknock, Radnor, all such parts of Salop, Worcester, and Warwick as are not included in a 20 mile radius from the General Post Offices at Birmingham and Wolverhampton respectively, and the Channel Islands. The district is clearly shown in the accompanying map Although the Western Company was not registered until December, 1884, the district was partially worked by the United Company as far back as December, 1879, by an exchange being opened at Bristol with 25 subscribers. The number now is 429 exchange and 82 private line, or a total of 511 renters. Clifton and Bristol are connected by trunk wires, with a switchroom at each place. Portishead Docks, 12 miles distant, and Avonmouth Docks, nine miles distant, are also connected with the Bristol exchange system. We think it worthy of notice that during the year ending 31st December, 1887, there were 625,631 calls to the Bristol Exchange, which, allowing a reply to each call, represents 1,251,262 communications. The year 1888 shows an increase over 1887 of 89,931 calls, or 179,862 communications; the 1888 total being 1,431,124.

An exchange was opened at Plymouth by the United Company in June, 1881, and trunk lines run connecting Devonport, Stoke, and Mutley, three towns which are practically one and the same. The company opened here without a license from the Postmaster-General for the purpose of testing the legality of their action. At this time there was a small exchange in Plymouth, which had about 20 subscribers, and was conducted by Messrs. Cox and Williamson, who were using instruments (microphone transmitter and Ader receiver) which were on July 25, 1882, decided by the courts to be infringements of the United Company's patents. This firm, however, were working under a Post Office license. Messrs. Cox and Williamson's business, exclusive of the instruments, was taken over by the Post Office, who gave notice to the United Company that not having a license they must close their exchange, they having at that time about 65 subscribers connected. The company then applied for a license, but it was refused, and the exchange was closed and remained so for some time. However, in spite of this, the Post Office never managed to obtain a larger number of subscribers to their system than 43. In February, 1885, the Western Counties Company having succeeded in obtaining a license from the Post Office reopened the old exchange of the United Company. When it came to a matter of competition, the Post Office had to give in, their subscribers gradually leaving them and going over to the company, and at length, in June, 1888, the official exchange was finally closed, while the company has now 251 subscribers.

This is briefly the history of the opening of the pioneer stations of the present extensive system worked by the Western Counties Company, and with this history the name of Mr. H. F. Lewis, formerly manager in the West of England for the United Company, now general manager and secretary of the Western Company, is most intimately connected. The following table A will give at a glance the history of the company's exchanges from their opening to the 31st December, 1888, with the number of subscribers to each:

Table A.

Name of town.	Date of opening.	No. of exchange subscribers.	No. of private lines.	Totals.
Bristol	March, 1879	429	82	511
Bath	Oct., 1886	53	28	81
Gloucester	June, 1887	40	23	63
Newport (Mon.)*	Jan., 1886	76	23	99
Cardiff*	Dec., 1885	117	49	166
Pontypridd	June, 1888	12	14	26
Swansea†	1887	137	27	164
Shrewsbury	June, 1887	29	25	54
Plymouth*‡	Feb., 1885	251	62	313
Torquay	Oct., 1885	151	26	177
Exeter*	June, 1887	38	33	71
Portsmouth	July, 1885	166	68	234
Bournemouth	Nov., 1886	188	23	211
Poole	Nov., 1886	14	1	15
Southampton	June, 1886	93	19	112
Weymouth	June, 1887	20	14	34
Jersey	Nov., 1887	26	—	26
Cheltenham	Dec., 1888	20	16	36
Worcester	Dec., 1888	6	15	21

* Opened in face of Post Office competition.

† The Western Counties Company bought up the original Swansea Telephone Company, which had been in existence since 1881.

‡ As we have explained above, this was originally opened by the United Company in 1881 and reopened by the Western Company in February, 1885.

Early in the present year the company expect to have exchanges open and in working order at Gosport, Tavistock, Dartmouth, Brixham, and other places. In the above table we have indicated the towns in which the company encountered Post Office competition by an asterisk. We may add, further, that at Newport the highest number of subscribers to the Post Office system was 44. It is now 35; the company having 68. In Cardiff the Post Office obtained 48 subscribers at one time, but have now only 33, as compared with the company's 117. Plymouth we have already spoken of. At Exeter, the Post Office have had an exchange since the year 1883, but never succeeded in obtaining more than a dozen subscribers—at least, so we were told—and have now closed their offices. The company, as will be seen, have in 18 months or so obtained 38 subscribers.

In the map, the existing exchanges of the company will be found marked black, those proposed to be or actually in course of being opened are lightly shaded

We will now give some account of the

Trunk Lines,

of which the company have an extensive system in work, and a still larger system in course of construction and proposed. Referring to the map again, a thick black line indicates lines completed, a thin and dotted line those in course of construction, and a dotted line those in the proposed stage. Starting from Bristol as the centre of the district, we find it connected by trunk lines with Bath, Portishead, Avonmouth, Sharpness Docks, and Gloucester. From Sharpness a line runs by a cable across the Severn, to Newport and Cardiff, from which places a loop includes the towns of Pontypool, Tredegar, Merthyr, Aberdare, and Pontypridd. From Cardiff, again, it runs to Briton Ferry and Swansea, where another loop includes the towns of Morriston and Landore. From Swansea the line runs to Llanelly, which is at present its farthest limit, though, as will be seen from the map, it is proposed to carry it on to the important town and docks of Milford.

Another group of trunk lines will be found centreing round Torquay, which is connected with Newton Abbot, Paignton, and Totnes. From this town a line, which is nearly completed, runs to Plymouth, and thence to Horrabridge and Tavistock. Eventually, this district will have lines running as far south-west as Falmouth and Camborne, and northwards to Bristol. The small trunk connecting Poole and Bournemouth is being extended to Southampton and Winchester, returning south again to Portsmouth and

Lines Completed ▬▬▬ Lines Proposed — · — · — · Lines in Course of Construction · · · · ·

The above Map is intended to indicate the towns telephonically supplied and proposed to be supplied, though the names of many important towns are omitted. Thus in the South Wales District—Llanelly, Swansea, Briton Ferry, Pontypridd, Cardiff, Pontypool, etc., are indicated but without names, as are Tavistock, Totness, Newton, Brixham, and Torquay, in the Devon District.

Gosport. Gloucester also will soon have a trunk line to Cheltenham, where an exchange has just been opened.

The following table B gives the route and wire mileage of the existing trunk lines between the various towns:

TABLE B.

Names of towns.	Route mileage.	Wire mileage.
Bristol—Bath	14	56
Bristol—Avonmouth	9	36
Bristol—Portishead	11	33
Bournemouth—Poole	6	36
Bristol—Sharpness	21	210
Sharpness—Newport	31	189
Sharpness—Gloucester	18	72
Newport—Cardiff	14	196
Cardiff—Swansea	50	264
Swansea—Llanelly	12	48
Interlocal group, Swansea, Briton Ferry, Morriston, and Landore	12	66
Newport—Pontypool	11	22
Pontypool—Tredegar and Merthyr	22	44
Merthyr and Aberdare—Pontypridd	15	60
Torquay—Paignton, Totnes, and Newton Abbot	15	18
Plymouth—Plympton	5	5

From this table it will be seen that the company have trunk wires in operation to the extent of 266 miles of route and 1,355 miles of wire. The same figures with regard to trunk lines in course of construction which are expected to be opened for use at no distant date, read as follows:

Name of town.	Route mileage.	Wire mileage.
Gloucester to Cheltenham	9	18
Bournemouth to Southampton, Winchester, Portsmouth, and Gosport	72	144
Cardiff to Barry	10	20
Torquay to Plymouth	33	66
Torquay to Brixham	8	8
Torquay to Dartmouth	11	11
Plymouth to Tavistock	12	12

or a total of 155 miles of route and 279 miles of wire. The total number of poles required for lines constructed and in course of construction has been 10,500. The longest distance spoken over at present is from Bath to Llanelly, 140½ miles. This circuit includes a cable across the Severn, one mile in length, running along the bridge at Sharpness, and another short cable running through the canal at Sharpness Docks.

With reference to

LINES PROPOSED,

it will be seen from the map that the company contemplate (we are informed at an early date) connecting their system with London, either through Bath, *via* Swindon and Reading, or by a line from Winchester through Basingstoke to Reading and the Metropolis. If the latter route be adopted, it will allow of the South Coast towns being put in direct connection with London, while a line from Winchester, *via* Salisbury, to Bath would connect Portsmouth with Bristol and Gloucester, and Bristol and the Welsh towns with London. Again, having established themselves at Portsmouth, the Western Company will only have a short distance to run (about eight miles) to the boundary of their district at Havant, where they could in the future make arrangements with the South of England Telephone Company to have trunk wires, connecting Brighton, Lewes, and Eastbourne, on the one hand, and Shoreham and Worthing on the other with the Western Counties' system, through a short line run between Worthing and Havant. This would put all these towns in connection with Portsmouth, Bournemouth, Winchester, etc.; in fact, it would place all the South Coast towns in intercommunication. We were informed that the proposal had been made to the South of England Company, but had been declined because they were unable to see that the proposed trunk lines

Digitized by Google

would prove remunerative. Looking at the map, and from our knowledge of the towns, we should think they are making a mistake in declining the proposal of the Western Counties Company.

The whole of the Western Company's trunk lines have been constructed of hard drawn copper wire, and are all metallic circuits. They have at present 190 annual renters on these trunks; in addition to which they have, of course, a revenue coming in from the public call offices in the various towns, where for a fixed toll anyone not a subscriber can speak with any subscriber to the system.

The tolls from Bristol to the undermentioned towns, or *vice versâ*, are as follows, three minutes' conversation being allowed, viz.: Bristol to Bath, 6d.; Sharpness, 6d.; Newport, 6d. Beyond Newport, and as far as Pontypridd, including the towns in the loop, the toll is 9d.; and beyond Pontypridd, 1s. On the Bournemouth and Torquay trunks the toll is 6d.

To show the use that is made of these trunks, we may say that the number of calls by annual renters during the month of October last was 12,754; by local subscribers from their own offices, paying toll, 997; and by the public from the call offices, 686; making a grand total of 14,437 for the month, representing the user of the trunks. That they are growing in favour with the business community is shown by the fact that the figures for the previous October (1887) were: Calls from annual renters, 5,734; local subscribers, 310; public from call offices, 288; total, 6,332—that is to say, the calls have more than doubled in one year, which is pretty conclusive testimony of the value of these lines to the public, even allowing for extensions of the system.

Colliery Work.

The company have devoted considerable attention to providing telephonic communication for mines and collieries. The advantage of connection between the underground workings and the manager's office or house, and between the latter and the nearest town, is obvious, not only from a business point of view, but also in cases of accident or other emergency. When every colliery is provided with the telephone and every miner with an electric safety lamp, the risks now run will be diminished to a vanishing point. The company obtained a silver medal at the exhibition of the Cornwall Mining Institute held last year for the excellence of their work.

Instruments and Apparatus Used.

Being licensees of the United Company, the instruments used by the Western Company are, of course, those made under the Bell and Edison master patents, to uphold which the United has expended such enormous sums of money. Their system of working varies at different places. At Plymouth, Portsmouth, and Bournemouth they use the multiple board of the Western Electric Company. At Bristol they work an improved form of Bell board, and at other exchanges boards of various types but principally the Western Electric Company's standard pattern. Three kinds of wire are used, according to circumstances—viz., hard-drawn copper for the trunks, silicium bronze, $\frac{3}{16}$in. galvanised strand, as well as hard-drawn copper, for ordinary town work.

Number of Calls Per Annum.

During the year ending December last the total number of calls through the exchanges and on the trunk lines of the company was 1,937,000, and as each call necessitates a reply, the total number of communications over the lines during the above period was 3,874,000.

A Trial of the Trunk Lines.

Whilst at the company's offices our representative had an opportunity, thanks to the courtesy of Mr. Lewis, the general manager, of talking over the trunk lines which radiate from Bristol. At 4.33 p.m. he rang up for Gloucester, distance 39 miles, got through in less than half a minute, and made a few enquiries as to the weather, etc. At 4.35 rang up Bath, 12 miles distant, and got answer at once. At 4.36 rang up Cardiff, spoke them, and at 4.37 rang up Newport, but found them engaged with subscriber. Then asked for Swansea, and got through at 4.39, *via* Cardiff. Then asked Swansea to switch through to Llanelly, distant 128½ miles, and spoke them at 4.40. So that in seven minutes conversation was held with five different towns widely divergent (*vide* map) over a total wire distance of 363 miles. The conversation in each case was confined to two or three short questions and answers, chiefly referring to the weather, but quite sufficient to test the speaking properties of the lines. In each case the articulation was remarkably clear, and in only one or two instances was any repetition of a question necessary. Curiously enough, Llanelly, the furthest point spoken with, could be heard more distinctly than other places nearer at hand. This may, of course, have been due as much to the speaker as anything else. On the other hand, it should also be noted that the weather was very much against telephonic communication. There had been a strong gale over the district the night before, followed by heavy intermittent showers during the day, while every town rung up described the weather either as rainy or very damp.

With reference to the remarkably short time in which each town was "got" and spoken with, it should be remarked that at this time of the day the pressure of business had somewhat subsided, so that all the lines were clear with the exception of Newport. During the morning and early afternoon it is, of course, not unusual for subscribers to have to wait five or ten minutes before they can obtain the use of the line. In such a case a subscriber does not have to wait at the telephone during this interval. A record is kept by the operators in the switchroom of every call, and when the line is clear each caller is rung up and put through in his proper turn.

Even allowing, however, for the exceptionally clear state of the lines, our experience warrants us in congratulating Mr. Lewis and his staff on the excellent speaking properties of the company's system round Bristol, and, considering that no preparation whatever had been made for our trial, we think, even when it is allowed that the conversation in each case was very short, the time occupied was remarkably good.

General Remarks.

We will conclude with a few general remarks. And, first, we must say a word or two concerning Mr. Lewis, the genial and courteous manager of the company's system. Originally general manager of the old Bell Company, in London, Mr. Lewis has been associated with telephonic enterprise since the first introduction of Graham Bell's beautiful apparatus into practical everyday use. In June, 1880, upon the amalgamation of the Bell with the Edison Company—forming the present United Telephone Company—Mr. Lewis was made the metropolitan manager of the new concern, and shortly afterwards was sent into the West of England to introduce and work the system there. We understand that it was owing to his efforts that the Western Counties and South Wales Company was formed, he being appointed general manager and secretary. The history of the spread of the telephone over the district allotted to this company cannot be dissociated from Mr. Lewis's name. Thoroughly well up in all the details of his work, gifted with untiring energy and unfailing pluck, Mr. Lewis has amply justified the confidence placed in him by his directors, and it will not be his fault if the company's district is not soon a vast network of telephonic communication.

Throughout the company's exchanges women alone are employed by day and men or boys by night. Mr. Lewis expressed a very decided opinion in favour of girls, as compared with lads or men, for exchange work. With regard to the other side of the question—viz., the girls' appreciation of the work—he remarked with evident pleasure that since he had been connected with this company (1884 to present time) he had never had a girl leave his employ on her own account except to get married. We think this is good evidence of the existence of an excellent feeling between employer and employées, and also of the fact that telephonic work is well suited for the utilisation of female labour. Possibly in the future, when further developments have taken place and every town of any importance has its exchange, we shall hear

Digitized by Google

less of the difficulty of finding suitable employment for "our girls." We were informed that girls have often left their employment in shops to come to the telephone company, and Mr. Lewis has a long list of names of those at present engaged in other vocations anxious to enter his employ when there is a vacancy, which list, he calculates, will be sufficient to supply him with employées for Bristol for the next five years. The exchange operators are very carefully chosen for the position, strict enquiries being made as to their respectability and fitness for the work. They start with a commencing salary of 6s. per week, and rise by gradual increments according to their merits, the chief operator in Bristol getting £1. 1s. per week. In other towns the pay is in proportion to the number of subscribers and the work to be done. The total number of the Western Company's employés is 260, of whom 84 are switchroom operators, 73 of these being girls. Night work is done by youths or men.

ELECTRICITY IN LONDON.

In our issue of last week, and also this week, we give a number of letters which have appeared in the *Times* upon this subject. On Thursday, our daily contemporary had a leading article based upon these letters, from which the following extracts are taken:

". . . . Hitherto the license and provisional order have lived side by side very amicably, for the apparent reason that there were no spoils to quarrel about. Electric lighting has for various reasons proved unprofitable to promoters. Since the passing of the Act of 1882 some 59 provisional orders and five licenses have been granted to companies, and fifteen provisional orders and two licenses to local authorities; and early last year it was stated in Parliament that the Board of Trade were not aware of any cases in which the powers thus obtained were being exercised. But within the last year or two electric lighting in this country has raised its head anew. How far the revival is due to the increased experience of electricians, how far to the success with which electric lighting has been worked in America, how far to last year's relaxation of the Act of 1882, or how far to generally stimulated trade, we do not profess to judge. We are inclined to think that the revival of electric lighting produced the Act of 1888 rather than that the Act revived electric lighting. However this may be, better days seem to be at hand. Some companies have been carrying on operations as best they can without either license or provisional order; several are about to apply for licenses; and two, anticipating the rest, have given the statutory notice of their intention to apply for provisional orders embracing the whole of the metropolis. The applicants for licenses only are indignant at this last piece of greediness, and thus the controversy of which we have spoken has naturally developed itself. The public will notice with some suspiciousness that the gentlemen by whom it is conducted are all directors or officers of rival electric lighting companies. We shall hardly be doing Mr. Hammond, Lord Crawford, and Mr. Erskine an injustice in supposing that their anxiety that the public should be well served is not entirely disinterested. Still, the self-denial of these gentlemen in ignoring all the private reasons which actuate them, and confining themselves to lucid statements of the public merits and demerits of provisional orders and licenses, is altogether praiseworthy. . . . .

"We desire to recognise the soundness of the principle which pervades Mr. Hammond's letter, that principle being the necessity of guarding against the creation of great monopolies. Taught by bitter experience, Londoners have every reason to be jealous of nascent undertakings for supplying them with light and water. But we may fairly consider that, in regard to electric lighting, public interests were sufficiently preserved by the Act of 1882, the safeguards in which were so stringent that they had to be relaxed in 1888. There are, in fact, two sides to the question. We do not want oppressive monopolies, but we cannot afford to throttle enterprise by stipulations which discourage investors. Lord Crawford declares that if the Board of Trade were to grant no provisional orders, but restrict itself to granting licenses pending the development of electrical knowledge, this would have just the same damping effect as the short tenure of 21 years and inequitable terms of pre-emption, which rendered the Electric Lighting Act of 1882 inoperative, and had to be altered by the Act of 1888. The requisite capital, according to Lord Crawford, could not be raised, for investors see no security and no prospect of adequate profits in the precarious tenure afforded by a license. To go back to a short tenure of not more than seven years just after Parliament has been driven to affirm the necessity of granting to the companies longer leases of life is a retrograde step. Such is Lord Crawford's view. It is almost impossible to lay down any hard and fast rule on the question. We can merely place the two principles —one directed against monopoly, the other against trammels upon enterprise—side by side, and observe that due weight must be given to each. We have full confidence that when it comes to particular cases the Board of Trade will use its discretion wisely. We should be sorry to see the entirety of the metropolis parcelled out among two or three companies on the principle of 'first come, first served.' We should be hardly less sorry if the Board of Trade, by any pedantic rules, checked for another interval the progress of electric lighting."

CORRESPONDENCE.

ELECTRICITY FOR HEATING PURPOSES.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Now that the supply of light and power to private consumers by a central electrical station is becoming so general, and as it is found to possess so many advantages, may I ask whether there is any greater difficulty in the similar supply of heating power by electric energy and transformations over the same areas? Surely there are simple methods of transforming electricity into heat, and this with but little loss of efficiency. Would not suitably constructed artificial metallic resistances easily adapt themselves to most of the purposes for which heat is required in dwelling-houses, without much outlay in plant, or complication of machinery?

Hollow tubes of very thin metal, or spirals of flattened wire in insulated chambers, would heat air (that would lose nothing of its purity by the process) in a most healthy manner, and which would serve many a useful purpose. Indeed, the advantages that would follow from the adoption of such a method of supply, I need not attempt to name; but think of the freedom from dust, dirt, coal, soot, ashes, *smoke*, and even fog, and tell me kindly, sir, why it is that this form of energy has to come to us in coal sacks; and whether our accumulators for it must always be coal cellars?—Yours, &c., HAROLD G. DIXON.

Guy's Hospital, S.E., January 4, 1889.

THE "MAXIM-WESTON" AND "HOUSE-TO-HOUSE COMPANIES.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—As many of your readers are aware, I have just succeeded (after three years of unremitting efforts) in inducing my fellow citizens to introduce the electric light into Bath for public and private use, and have obtained from the Corporation a seven years' contract (on behalf of a local supply company) for the public lighting of 50 of the principal streets, squares, and crescents of this city with arc lamps. Plant will shortly be put down for 200 arcs and 10,000 incandescents. I am not, as many suppose, a professional electrical engineer, but only an enthusiastic admirer of "the light of the future." During the past four years I have unstintingly spent my own time and capital in introducing electricity into several towns in the West of England, in the prosperity of which I am personally interested.

To my surprise, just as we are on the eve of forming our local company, the House-to-House make an application to the Bath City Council asking them to sanction their applying to the Board of Trade for a license for lighting the same area for the same term of years. What is the meaning of this application? Are the House-to-House Company imitating the behaviour of the Maxim-Weston Company when under the chairmanship of Mr Hugh Watt, M.P.? The unjustifiable interference of the Maxim-Weston, some twelve months ago, just as the Commissioners of Sewers were contemplating entering into a contract with the Brush Corporation for the lighting of the City was not only a loss to that particular company, but still more so to the whole of the electric lighting industry. The only effect of this application is to frighten a certain number of timid investors who will be afraid to apply for shares in the Bath Electric Lighting Company if labouring under the mistaken impression that it is going to be subjected to the competition of a powerful London company with an unlimited amount of capital behind it.

Even if the "House-to-House" possesses the necessary capital to erect a large central station, they would obtain no custom, as they could not compete with the local company except at a ruinous loss. The sooner companies which pursue this "dog in the manger" policy cease to exist the better it will be for the electric lighting industry, the growth of which they retard by their short-sighted policy. I trust that this candid expression of my views may produce beneficial results.—Yours, &c., H. G. MASSINGHAM.

[We think Mr. Massingham's views are those of all interested in the true welfare of the industry.—ED. *E. E.*]

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical-Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

OUTSIDE AND INSIDE.

Perhaps of all the lighting schemes that have been attempted, those at Barnet and Leamington have been subjected to the most violent criticism. It was our duty in schoolboy days to attend a series of lectures by an eminent lecturer whose subject was the rise and fall of various religious movements that had agitated the world. Very few of the worthy lecturer's remarks made a permanent impression, but one was forcibly impressed to the effect that religious or any other movement—for the moral was widely applicable—went wrong rather from internal dissensions than from external attacks. We humbly apologise to the rev. lecturer for the base use to which we are applying his conclusions, viz., that if the electric lighting industry, instead of progressing and flourishing, goes backward, the result will arise from internal and not external causes. Now we are not going to trouble our readers with many words about internal criticism, which, though the most dangerous, is not likely agaiu to become prominent without some extraordinary mistake on the part of electrical engineers. What we wish to refer to is the attitude of the ordinary local and metropolitan press. Most writers, however ignorant upon technical matters, believe themselves quite capable of determining the photometric power of rival lights. Then they imagine they know all about gas. They admire the simplicity of its distribution and ease of manipulation. It is a tool they are familiar with, while we would hand them a tool about which they have heard much and experienced little, hence "the bird in the hand is worth two in the bush." Again, most of the gas companies are local concerns, and whatever affects gas, affects the pockets of shareholders. Usually some member or members of the local board or town council are directors of the gas company, and of course anything about electricity provides the red rag at which the bull incontinently rushes. They are in possession, and strenuously defend themselves against attack. The local press deals with local politics, and reports at great length the sayings and doings of those connected with gas companies—because they are so connected. The men who wish to introduce improvements are generally looked upon as busybodies, as men who can't let well alone, and are not infrequently the best abused men in the town. The external attacks, then, upon the electric lighting industry come from these quarters, and cannot be said to be the outcome of knowledge, but are the natural features which must always accompany change. Of course, the technical journals connected with the gas industry follow the cue given them by the prominent members of the profession. They can hardly be expected to view the progress of electric lighting with feelings of unmingled gladness. If any man is desirous to see the worst that can be

said or thought about electric lighting, let him read the weekly gas journals. It has been again and again suggested to us that the peculiar twisting, plain simple facts undergo at the hands of writers in these journals, to make them appear somewhat different to what they really are, should be "shown up," but our invariable reply is that such criticisms show the wish to be father to the thought, while, in the long run, they are comparatively harmless. They come from interested quarters, and are usually taken *cum grano salis*. Now, both external and internal criticisms have been hurled against Leamington and Barnet. The commencement of this year of grace sees success at both places—success absolute, even if not unqualified success. With regard to Leamington, the lighting is of two kinds—public and private. There have been continuous squabbles about the former, none about the latter. Both the lighting of private houses, places of amusement, shops, etc., and the street lighting of the parade are carried out by Messrs. Chamberlain and Hookham from the same central station, and while they have always been able to give entire satisfaction to their private customers, they have never been able to satisfy the town council as to the street lighting. At present more than double the light is given than used to be given with gas, yet the powers that be are not satisfied. Is it that they want artificial moonlight or sunlight, but are not willing to pay for it? The charge for the street lighting is not equal to 3d. per unit, and when we have said this, it is sufficient to explain that the suppliers are more or less indifferent to the continuance of this particular lighting. An extension of house-to-house lighting would pay better and be more satisfactory to all the parties concerned. We take it that the inability to satisfy the council means simply inability to satisfy the gas interests represented on the council. With regard to Barnet, the contractor, Mr. Joel, has had by no means an easy or happy time. The suggestion to light electrically began, we believe, with a squabble with the local gas company, and it was not likely the gas interests were or are going to cry peccavi without a hard struggle. The gas company thought to put pressure on, and have its own way. The rival is steadily forcing its way against all opposition into popularity. Before leaving this part of our subject we may direct attention to the letter of Mr. Massingham from Bath. We do not hear of a second gas company trespassing upon the local habitation of another local company. Surely the country is wide enough without these internal dissensions. These actions are more dangerous than all the open or covert attacks from gas. The company referred to could hardly be unaware of the work done by Mr. Massingham to influence the rulers of his native city to adopt the electric light.

Let us again suggest that more money is to be made by installing a *light* and *power* station in a working neighbourhood than by installing a light station in an aristocratic neighbourhood. You engineers fight shy of power, you only refer to it as holding a secondary position. We think it far more probable that even in the immediate future power will take first, and light have to be satisfied with second place. Try it. Canvass for power as assiduously as you canvass for light. You will be astounded at the promise of return that distribution of power gives in comparison with that of distribution of light. The small consumers of power consume it in the most wasteful and uneconomical manner possible, and they probably pay for a single horse-power fifty or a hundred times as much as is paid for a horse-power by a railway or a ship owner. The English engineer seems perfectly blind and helpless in this question of power. He is probably waiting till his American confrère steps in and shows him how it is to be done, when he will scream at the go-ahead Yankee for trespassing upon the home preserves. We have no sympathy with this state of things. If the English engineer won't, then let the French, German, or American come in. There was an absurd suggestion made by one of our contemporaries the other day about driving Wimshurst machines to dissipate fogs, showing how utterly ignorant the writer is of the first principles of business. He might have written, "Burn coal, burn it wastefully, burn more to drive machinery to get rid of what you are burning wastefully." Artemus Ward would have said, "Sound advice, truly," but we would rather see no coal burnt wastefully. We know that Yorkshiremen believe that where there is "no muck there is no money," but it may well be doubted whether too much muck increases the money. Do doctors advise the slashing of an arm or leg an extra inch or two just for the mere purpose of adding another plaster? Where is now our old copybook headline, "Prevention is better than cure," which used to be looked upon as axiomatic, but some people have lost faith in it, and read it the other way up, "Cure is better than prevention."

Morals for this week:

Internal dissensions are worse than external attacks.

Power and light rather than light alone—hence working not aristocratic districts for central station installations.

Report of 1888 Continued.

Blakey, Emmott, and Co. have been exceedingly busy during the past year in their numerous departments of electrical engineering and electric light. A large demand has ruled for their new type of single magnet dynamo, and some good orders have been obtained from abroad. Numerous factories, public buildings, and private mansions in the North of England have also been lighted by

Digitized by Google

this firm. In their instrument department the "Blakey-Emmott" volt and ammeter have been in large demand, we suppose by reason of the non-liability to get out of adjustment and easy portability. The "Robinson" lamp, which is introduced by this firm, promises to occupy one of the leading positions among arc lamps, and we hope to describe and illustrate it at an early date. The company are also exceedingly busy in their cable and wire departments, having during the last year greatly extended this branch, and are now working night and day to fulfil their orders, they making several special classes of electric light cables and leads, which have found very great favour abroad.

DRAKE AND GORHAM have completed a large number of isolated installations during the past year.

At the Bank of England a steam-engine of 50 h.p. has been put to work for lighting purposes, and two large gas-engines will be started in a few days to supply another portion of the bank. Several of the more important offices are already fitted with incandescent lamps, and it is expected that before long the gas will be used only in the corridors and offices of minor importance.

The incandescent installation at the Prudential Assurance Company's office has been completed, and the plant is capable of supplying 3,500 60 watt lamps, and may therefore be regarded as a central station in itself. The plant consists of three Marshall horizontal engines of 110 h.p., six 600 light dynamos, and 264 cells, made to the firm's latest specification.

An installation has been fitted at Baron Schroeder's country residence, with two gas-engines, and the whole of the lighting at Lord Armstrong's seat, Cragside, has been rearranged and extended, Elwell-Parker dynamos and motors being substituted for those previously in use for both lighting and motive power.

Complete installations, with plant, have also been carried out for A. S. Freeman-Mitford, Esq., the Society of Antiquaries, Sir William Plowden, K.C.S.I., Messrs. Johnson, Budd, and Johnson, S. Courtauld, Esq., Alfred Apperby, Esq., F. E. Marshall, Esq., Harrow Schools, J. Saunder-Gilliat, Esq., A. Kingsmill, Esq., W. Abercrombie, Esq., and ship-lighting batteries fixed on H.M. the Queen's yacht, H.R.H. the Prince of Wales's yacht, H.M.S. "Britannia," and a number of private yachts and steamships.

Several improvements in accumulator plates have been patented and put into work during the year, which are already found to be a material advance. A number of electrical hoists have been erected for various purposes.

The firm is paying special attention to the production of measuring instruments for regular work, and has purchased the Cardew patents for voltmeters and brought out a new pattern ammeter of its own.

ELWELL-PARKER, LIMITED.—This company has had, on the whole, a very prosperous year. They have increased their establishment and the number of employés, until the latter number 430; and the works at present are running with a night and day set, with plenty of orders in hand. The company has in the year increased the alternating-current plant at the central stations of Eastbourne and Brighton, and supplied a full central station alternating-current plant to South America. The whole of the plant is now supplied to the House-to-House Company's station at South Brighton, and they have also supplied the whole of the plant for two other central stations, also the accumulators for that at Liverpool. They hold orders for Whitehall, Leeds, and further orders for Liverpool, Brighton, and Melbourne. This company has during the year supplied and tested thoroughly in Wolverhampton, in the presence of many distinguished gentlemen (including the directors of the Manchester Carriage Company, representatives of the borough surveyors, Birmingham, and the various technical press), a car built to the Julien lines for Mr. E. Pritchard, Sydney, who has since demonstrated sufficiently in Sydney the advantages of accumulators to be able to obtain several large contracts. They have added to this an experimental locomotive, built also for the Julien Company, of England, and made to compete with the steam tram-engines in Birmingham. This has been placed in the hands of the Central Tramway Company, Birmingham, for this purpose, and has been submitted to the severest possible tests over an extended period of two months, having given thorough satisfaction to the tramway company and the borough authorities, and seems to have attained a thoroughly practicable issue for the application of accumulators to the purpose of driving tramcars. They have recently supplied further motors to the Brussels Tramway Company, to be used with accumulators for tramway work. These are repeat orders, the company having supplied the earliest motors. Motors have also been supplied to the Series Traction Syndicate for their new line at Gravesend, and a complete tramway plant for overhead driving to Australia. The plant at the General Post Office has been extended during the year, and orders are in hand for further increasing the plant for the Savings Bank Department. Dynamos have been supplied to various Government departments. Our readers will also remember that Messrs. Elwell-Parker supplied the plant for the installation of the Corporation-street Estate Company at Birmingham.

FOWLER, LANCASTER, AND CO.—Like most of the firms engaged in electrical work, the report of the work throughout the year is favourable. The whole twelve months have been exceedingly busy, especially in the manufacturing department, the business of which has so much increased that arrangements for the extension of the premises have been made. An enormous quantity of switches, cut-out cases, fuse-boxes, ceiling and wall connectors, and lampholders, etc., have been turned out in china, which this firm were the first to perfect with regard to the screwing together of the bases and covers, and in this department has been more than filled with orders, and there are now sufficient orders in hand to be very busy for some time to come. A considerable business has been done in railway and instrumental work.

Among other contracts that have been carried out, is that of the lighting of a portion of the works of Messrs. Perry and Co., of Birmingham, by 400 incandescent lamps of 6 c.p., each of which replaces a 4ft. gas-burner, the result being that, after keeping most careful statistics, it has resulted in a saving over gas, and a considerable decrease in the expense for doctor's attendance to the female hands employed. There were also about 40 lights of 16 c.p. in the office of the company. In addition to the above, an installation has been put in at the residence of Martyn Smith, Esq., of Abberton Hall, Pershore, including a 50-light Fowler-Lancaster dynamo, driven by a Spiels petroleum engine and a set of E.P.S. accumulators; also an installation at the residence of W. E. Wiley, Esq., of Erdington, consisting of 75-light Fowler-Lancaster dynamo, which is driven by an Otto gas-engine. These are instances of installations carried out under somewhat unusual conditions, each of which has given the utmost satisfaction, and in the case of Messrs. Perry and Co. the contract is in hand for an extension of lighting, to the entire replacement of gas in the works.

A good deal of work has been done in wiring and fittings, and an extensive trade in switches, etc., both at home and abroad.

GENERAL ELECTRIC COMPANY.—This company have strictly adhered to manufacturing for the trade only. The business is in two departments, both of which have been fully employed during the last twelve months. The electric light department did a very considerable turnover in the supply of a great number of "Apostle" carbons, glass shades, and other electric light fittings. In order to obtain increased facilities to extend the business for switches and fittings, the works formerly carried on under the name of Sudworth and Co., Limited, have been bought and have been considerably extended. At the same time the firm has acquired the Manchester Electric Works, 45, Chapel-street, Manchester, in which there is room to occupy 400 to 500 men, though at the present time only about half that number are employed. The sale of instruments, more especially Aron meters, has increased with the number of central stations which have appeared in the last year, and in this department they look forward to a bright future.

Digitized by Google

The strict interference of fire insurance companies with contractors has, if anything, been a great advantage, in so far as the demand generally is now for goods of a high standard, and the firm has supplied a great number of elaborate switchboards, the orders for which, it is believed, are entirely due to the strict specifications insisted upon by the fire offices. The demand for English manufactures on the Continent and in the colonies has shown a considerable increase during the last year, though this increase is more noticeable in the electric bell department, where, especially from Australia, extensive orders are received by every mail. This department has also increased proportionately to expectations, and it is satisfactory to see daily new firms interesting themselves in this branch of electricity.

GALWAY ELECTRIC COMPANY.—It may interest our readers to know that out in the far West of Ireland electric lighting is making its way. For some time the Galway Company have illuminated a part of the old town with arc lights, and are busy now with incandescent lighting for private work, and they have, we are glad to find, a number of enquiries for motive power. This is a private local company, represented professionally by Mr. James Perry, M.E., the county surveyor of Galway, and Mr. Arthur W. Slater, A.I.E.E. The company has acquired some extensive works, with ample water power, and have made arrangements for more power should they at any time require it. The proposals for lighting the town are being considered, and it looks a good sign that the commissioners have informed the gas company that their arrangements with them may end with the financial year.

J. H. HOLMES AND CO., Newcastle-on-Tyne, and 17, Coleman-street, London, have been very fully employed during the year, and have been obliged to run their factories night and day for some months past in order to cope with the demands placed upon them. The firm have carried out a large number of installations in mills, shops, etc., but the greater part of their business has been done with electrical engineers at home and abroad.

LIVERPOOL ELECTRIC SUPPLY COMPANY.—During the past year the Liverpool Electric Supply Company have very largely extended their system of supply. They have now three central stations in use, and are supplying daily about 3,000 incandescent lamps and a small number of arc lamps. The company are engaged in laying a system of underground mains on the Callender system in the chief streets of the business portion of Liverpool.

ELECTROLYSIS OF COPPER SALTS.

BY ALEXANDER WATT.

With the exception of the sulphate, the cyanide and some few other copper salts, the electrolytic examination of solutions of this metal does not appear to have received so much consideration as the subject merits—not alone from the interest which always attaches to the electrolysis of metallic solutions, but also from the possible advantages which such experiments may offer to the practical operator, which latter consideration, I may frankly state, has always been paramount in all investigations of this character which it has been my pleasure to conduct. In carrying out the experiments to which I now desire to direct attention, the current was obtained from a modified Daniell battery which I invariably use for such purposes, owing to its regularity and constancy, and the very little attention required to keep it in working order. This arrangement consists of a quart stone jar, in which is placed a cylinder of sheet copper with conducting wire attached; a porous cell, in which is a cast bar of zinc, amalgamated, and having a conducting wire cast into the metal; the outer vessel is filled with a saturated solution of copper sulphate, slightly acidulated with sulphuric acid, and the porous cell filled with a 1 : 12 solution of sulphuric acid. About half a dozen of these cells are kept ready for immediate use, the current from one cell being always tried first, and one or more cells connected in series as required. The E.M.F. of this battery, as measured by the Walsall Electrical Company's voltmeter—which, by the way, is a very delicate instrument, and well suited for electroplaters—is 1 volt, and the current, measured by a Siemens' dynamometer, 1·073 ampere. The anode consisted of a plate of electrolytic copper, to which was soldered a copper conducting wire; and the cathode, in most instances, consisted of a steel plate one inch wide and about three inches long. All the solutions were electrolysed at the ordinary temperature.

In pursuing the experiments, it was determined to pass by such electrolytes—ordinary sulphate of copper solutions, for example—as were more commonly known, and to devote attention more especially to those which had received less consideration. Moreover, well knowing the difficulty of obtaining thick deposits of copper upon iron in sulphate baths, without giving the work a preliminary coating in an alkaline coppering solution, and the defects which cyanide baths present for this purpose, it was my desire, if possible, to find out some solution of copper which, having no chemical action *per se* upon iron, might be practically employed as a substitute for the cyanide baths ordinarily used.

1. *Oxide of Copper in Chloride of Ammonium.*—A hot solution of salammoniac was first prepared, and to this was added, a little at a time, recently precipitated hydrated oxide of copper, until the ammonium salt became sluggish in its solvent action, when the liquid was set aside to cool and settle. The resulting solution, which was of a pale blue colour, was then decanted for use. A steel plate being immersed in this solution for a minute or so became very slightly and partially coated with copper. It was next tried with the current from a single Daniell, when a steel plate at once received a film of copper; after a few seconds, however, the metal assumed a dark purple-brown colour. On wiping the plate with the finger, this brown deposit became dislodged, leaving a bright film of metallic copper beneath, which was very adherent, and firmly withstood hard scrubbing with moist silver sand. The solution was next diluted with water, after which deposition took place more gradually, and the film continued bright for a much longer period. After a few minutes, however, the deposit again assumed the purple tone, from the formation of powdery metal, but when this was removed by scouring, the subjacent layer of copper was found to be firmly adherent. By further dilutions of the solution it became greatly improved, and the non-adherent coating almost ceased to appear.

2. *Oxide of Copper in Sulphate of Alumina.*—A bath was prepared by digesting moist hydrated oxide of copper in a hot solution of commercial sulphate of alumina, in which the oxide became very freely dissolved, forming a green liquid. When cold, the clear liquid was first tested with a steel plate, which, by simple immersion, soon became coated with a firmly-adherent film of copper. The solution was next electrolysed with a single cell, a steel plate, as before, being used as a cathode, and this promptly received a film of copper, but as the deposition was too speedy for an adherent coating, it was found necessary to dilute the liquid by repeated additions of water until deposition proceeded more gradually, when the deposit eventually became firmly adherent, though somewhat wavy and irregular in appearance, the final dilution having been carried too far.

3 *Acetate of Copper.*—A solution of this salt was prepared by dissolving verdigris in hot commercial acetic acid, the resulting solution being afterwards filtered and diluted with water, in varying proportions, until the copper deposited upon a steel plate became more or less adherent. It was not until the liquid had been considerably weakened that the metal exhibited a disposition to adhere to the cathode. The current from one cell was used, with a small anode surface, and it was found that the metal was more adherent when the steel plate was kept briskly in motion while in the bath.

4. *Acetates of Copper and Soda.*—A small quantity of acetate of soda was added to the above solution, in the hope that this would cause the copper to adhere more firmly to steel or iron, and such really proved to be the case, for the deposited metal now required hard scrubbing with sand

Digitized by Google

to remove it from the plate. There was, however, still a tendency for the copper to strip or peel off certain parts of the plate. On examining the anode it was found to be coated with a deep orange-red film of oxide, which was readily removed by dipping the plate in hydrochloric acid. By simple immersion a strip of sheet iron did not become coated with copper in this solution.

5. *Acetate of Copper by Electrolysis.*—About equal parts of commercial acetic acid and water were put into a glass vessel, and in this liquid was immersed a pure copper anode and a platinum cathode, and the current from two Daniells allowed to pass, when in the course of a few minutes the platinum acquired a slight film of copper. A steel plate was then substituted, which soon received a coating of copper, but the metal was not adherent. A freshly-prepared plate was then immersed, and briskly moved about in the solution for several minutes, when it was found that the copper adhered firmly to the steel. The bath was afterwards strengthened with metal by immersing a large copper anode and small strip of the same metal for the cathode, and the electrolysis sustained with the current from two cells for some hours, after which the resulting solution was diluted with four times its volume of water. This solution, worked with a single cell and small anode surface, failed to yield a perfectly adherent film of copper when the steel cathode was allowed to remain stationary in the bath, but, as before, a more adherent coating was obtained when the plate was kept in motion.

6. *Sulphates of Copper and Ammonium.*—The object of this experiment was to ascertain whether the addition of the ammonium salt to a solution of sulphate of copper would promote the adhesion of copper to steel or iron, which it is well known cannot be successfully accomplished in solution of the simple sulphate. For this purpose, about equal parts of the respective salts were dissolved in hot water, and the liquid then set aside until cold, when pale-blue crystals of the double salt were found at the bottom of the vessel. The concentrated solution was next diluted with an equal bulk of water and electrolysed with one cell, when it was found that the deposit of copper upon a steel surface was tolerably adherent. Fresh additions of water were afterwards made, a new steel plate being immersed after each addition, and it was found that the adherence of the deposited copper was progressively better as the liquid became more dilute. Although the mixed salts certainly yield a more tenacious coating than could be obtained from the sulphate alone, it cannot be said that the solution referred to would be absolutely reliable as a coppering bath so far as the tenacity of the deposited metal is concerned. On examining the anode it was found to be coated with a yellow film, a portion of which firmly adhered to the plate. A solution was next prepared, by dissolving the crystals of the double sulphate found in the foregoing concentrated solution, in cold water. This bath was then tried with the current from a single cell, when the steel cathode soon became coated with a golden or orange-coloured film, changing to bright yellow, while patches of a purple tint appeared upon portions of the plate. On removing the plate, and scouring it with silver sand, a pale copper film became exposed, which adhered fairly well to the steel surface. On returning the scoured plate to the bath and keeping it in motion, a tolerably adherent film of copper was obtained, but this again assumed various coloured tints when allowed to remain stationary for a few moments.

7. *Sulphates of Copper and Alumina.*—Weak solutions of the respective salts were mixed, and the compound solution worked with a single Daniell cell. On immersing a steel cathode, a wavy, irregular film was at first obtained, when the plate was removed and rescoured with silver sand; soon after it was returned to the bath the film at once assumed a golden-yellow colour, which, but for the results obtained in the preceding solution, might have suggested that possibly a small quantity of aluminium had deposited with the copper, forming aluminium bronze. It was certainly remarkable that the same yellow deposits were obtained in each case. The yellow film referred to required hard scrubbing with sand to dislodge it from the steel plate.

8. *Potassio-tartrate of Copper.*—To form a solution, 120 grs. of bitartrate of potassa (cream of tartar) were dissolved in about eight ounces of hot water, and to this solution was added, by degrees, moist hydrated oxide of copper, the mixture being boiled after each addition of the oxide, which freely dissolved in the tartrate solution, forming a dark-blue liquid. The vessel was then set aside until cold, when the clear liquid was decanted for use. A steel plate slowly received a bright coating of copper in this solution by simple immersion. The liquid was next tried with the current from a single Daniell, a platinum cathode being used, which became slowly coated with copper of a darkish colour, while the edges of the anode, which did not appear to dissolve in the solution, became fringed with a bright green salt, the remainder of its surface being marked by vertical streaks of a brownish colour. A steel cathode was next used, when the green powder at once disappeared from the anode, but this electrode still remained "dirty," however, as though it were but little acted upon by the solution. Almost immediately after immersing the steel plate it received a film of copper of good colour when kept in motion, but when allowed to rest undisturbed for a short time the deposit acquired a dull and darkish tone. The film was non-adherent. The liquid was next diluted with an equal bulk of water and a fresh plate immersed, when a very prompt deposit of copper was obtained, which, as before, was non-adherent. Repeated additions of water were afterwards given, with a view to obtain a coherent deposit, but although the adhesion of the copper greatly improved after each addition of that liquid, the final result was not altogether satisfactory. A solution of this character was tried by Smee, who held the opinion that the anode is very slightly acted upon in a solution of the potassio-tartrate, and my own experiments certainly sustain that view. Dr. Elsner, however, asserts that the anode dissolves readily in such a liquid. By the simple immersion method this solution deposits copper of good colour, and very adherent upon steel, and probably it might be useful for coppering small steel articles, as buttons, etc., to be afterwards bronzed by a solution of potassium sulphide or other suitable material.

8. *Chloride of Copper.*—A solution of this salt was prepared by dissolving 120 grains of the crystals in eight ounces of cold water. The current from a single cell was used, and a very small surface of anode immersed. A very quick deposit of copper was obtained upon a steel plate, but the film was readily scoured off with moist sand. The solution was then diluted with an equal bulk of water, when deposition was still too quick, and the metal non-adherent, as before. After further dilutions with cold water the metal adhered more firmly to steel, but not sufficiently so as to render the solution practically available—that is to say, reliable. The anode did not keep clean in this bath, but became coated with a yellow deposit.

9. *Chlorides of Copper and Ammonium.*—Salammoniac (chloride of ammonium) was added to the foregoing solution with a view to improve the character of the deposit so far as relates to its adhesion to steel and iron. The addition of the ammonium salt was found to act beneficially in this respect, especially when the steel plate was kept moving in the bath, and, indeed, the deposits obtained in the altered liquid were so far adherent as to withstand the pressure of a steel burnisher without stripping or blistering in the least degree. It is not improbable that a solution carefully prepared from these salts might be useful as a depositing solution, more particularly if the articles could be kept gently in motion while deposition is taking place. This bath, however, would be useless for coating zinc articles, for a strip of this metal acquired a deep black colour a few moments after immersion. It should be mentioned that the anode after a time assumed a deep red colour.

10. *Chlorides of Copper and Sodium.*—A solution was prepared by adding to a weak solution of chloride of copper, in small quantities at a time, chloride of sodium (common salt), which was dissolved into the liquid by stirring. This bath was electrolysed with the current from one cell, and its behaviour may be said to be precisely similar to the foregoing in every respect—the anode, as before, acquiring a deep red colour. A steel plate, when briskly agitated in

Digitized by Google

this solution, received a firm coating of copper of good colour.

11. *Chlorides of Copper and Potassium.*—Small quantities of chloride of potassium were added successively to a weak solution of the copper salt, a steel plate being tried after each addition. Although there was a close similarity between this and the two preceding solutions, the results obtained from the present combination were scarcely so satisfactory. It was noticed that when a steel plate was immersed in this bath for a few seconds—a single Daniell being used—that the film of deposited metal acquired a deep red colour, turning somewhat purple after a while.

12. *Ammoniuret of Copper.*—A solution was prepared by adding liquid ammonia to a solution of sulphate of copper until the precipitate at first formed became dissolved; this solution was then tried with the current from one, two, and three cells in succession, but even with the latter, in series, there was a very slight tendency for the copper to go down on a steel plate.

13. *Ammoniuret of Copper and Salammoniac.*—A small quantity of salammoniac was added to the foregoing solution, and dissolved with stirring. On immersing a steel plate (the current from two cells being used) this at once became coated with a bright film of copper, which was found to adhere to the steel very firmly. A plate of zinc immersed in the liquid readily became coated with copper, which at once alloyed itself with the zinc, forming a yellow film of brass. A solution of this character might be useful for coating iron and steel.

14. *Arsenite of Copper in Cyanide of Potassium.*—To a hot solution of cyanide of potassium was added, in small doses at a time, arsenite of copper, and the mixture stirred until the copper salt was dissolved. The object of this experiment was to ascertain whether an alloy of copper and arsenic would deposit from this solution. Such was not the case, however, for the cathode (a steel plate) became coated with an iridescent film—first blue, then yellow, followed by red, yellow, and blue again, but there was no appearance of metal as such.

15. *Arsenite of Copper in Hydrochloric Acid.*—The green salt was added to hydrochloric acid, and heat applied until it became dissolved, forming a yellowish-green solution. This was next diluted with water, when the liquid at once became colourless. With the current from one cell a steel plate received a black deposit of arsenic at its lower end, while a band of copper appeared upon its upper surface, and the intermediate deposit between these two films appeared to be an alloy of the two metals, copper and arsenic. When a freshly prepared plate was kept in motion, while in the liquid, a bright film of arsenic appeared at the lower end of the plate, a streak of copper above as before, while the surface between these deposits had a yellowish tint, which was doubtless an alloy of the two metals. The solution was now further diluted, and a steel cathode allowed to rest in the solution for a short time, a very small anode surface being immersed. On examining the plate after a few minutes, it was found that a bright film of arsenic had deposited upon both sides of the plate, but when this was again moved briskly about in the bath patches of copper appeared at the back of the plate. The anode was freely dissolved in this solution.

(To be continued.)

ELECTRIC LIGHTING OF THEATRES.—II.

We sketched out in our first article some of the general advantages of electricity over gas for the lighting of theatres, and we shall proceed to describe in detail the various theatre installations in London. Besides particulars of the plants laid down, and of the numbers and arrangements of the lamps lighted, we shall endeavour to give the opinions of the managements and of the engineers in charge, as far as we have been able to obtain them, with regard to the advantages which in their own theatres they consider specially important in the use of electricity for lighting, with any other details of a similar kind which are the result of experience. The articles will be submitted in proof to the management and the engineers, and will thus bear, as far as possible, a certain authoritative value.

The consideration of a connected series of installations for the one special purpose of theatre lighting, together with the result of the practical experience now obtained, should lead to useful information to those who are likely to be engaged in this class of work.

ALHAMBRA.

The introduction of the electric light into this theatre has been eminently satisfactory to the management. The auditorium—with the exception of the gallery—and a portion of the stage is at present electrically lighted, and the plant they possess is fully loaded, but we believe that the directors only wait to be further assured of the reliability of supply of electric energy by public companies before deciding to receive the current they require from outside, and to light the whole of the stage as well as the house. The plant is situated in the basement below the dressing-rooms and wholly behind the proscenium wall; it consists of two Otto gas-engines of 9 h.p. nominal each, of two Edison dynamos, and of two sets of accumulators containing 54 cells in each set. In order to ensure great steadiness in the light, each gas-engine has two flywheels, and the dynamos, which are driven by belting direct without counter-shafting, have also each a small flywheel. The dynamos are shunt-wound for an E.M.F. of 110 volts, and the average current they furnish is about 80 amperes. There are two sets of accumulators, of the Elwell-Parker type, of 23 and 31 plates per cell respectively, with a capacity of 1,200 ampere-hours; these are contained in a separate cellar.

The resistances used for varying the degree of light from the foot-lights are of hoop-iron, and six degrees of light are possible. The instruments used in the engine-room are an ammeter and a voltmeter of the Ayrton and Perry spring form, and a Sharp and Kent ammeter. The float, the pit floor, and the grand circle floor are lighted direct from the dynamos, and one set of the accumulators lights the top balcony, the other set being kept in reserve.

In the float there are 80 16 c.p. glow lamps; on the pit floor 61 16 c.p., and four 32 c.p. lamps, the latter being over the bars; and in the balcony there are 104 16 c.p. lamps. The electric lamps are arranged for the most part round the auditorium in elegant brass brackets, each of which carries three incandescent lamps, and have a very pleasing effect.

The whole of the work, including the fittings, are by B. Verity and Sons, of King-street, Covent Garden. The gallery is still lighted by gas, as may be seen on looking up from the stalls by the flickering of the light, while the light emitted by the glow lamps is absolutely steady. We are told that the behaviour of the plant has been perfectly satisfactory, and that no trouble at all has been experienced with it from the commencement.

The cost of lighting since the introduction of the electric light has been about the same as before, but more light is obtained. No reduction in the insurance has yet been obtained in this theatre by putting down an electric installation, although the building has the further advantage of being constructed with concrete and iron, and is therefore of fireproof construction. The theatre was redecorated in April last, and it is stated that a marked difference in the rate of tarnishing has been observed, to the advantage of electricity.

The management consider that the absence of ascending streams of heated air from the foot-lights is very important, as the actors can with ease and comfort approach the very front of the stage. In the ballets this is really equivalent to an enlargement of the stage, and that in the best direction—viz., towards the audience. Great stress is also laid on the advantage of the general coolness and purity of the atmosphere in the auditorium of the Alhambra since the lighting of it by electricity.

Special Effects.—The electric light is occasionally used for special scenic effects at the Alhambra ballets. In one of the recent dances the fairy carried a 50 c.p. incandescent lamp, with a reflector throwing a strong beam of light from her head towards the audience with dazzling effect. This

Digitized by Google

was obtained by running a lamp of very much lower voltage—say, 90 volts or so—on the 110 volt circuit. A brilliant light, nearly equal to an arc, was thus produced, but of course could not be kept on for more than a few minutes each evening.

In the new Christmas ballet, "Irene," the electric light forms a feature in one of the scenes with very pretty effect. A large number of 5 c.p. lamps are used, on a blue background, to represent stars brightly shining on a moonlight night.

ELECTRIC LIGHTING.

LICENSES OR PROVISIONAL ORDERS.

The following letters have appeared in the *Times* upon the subject of Mr. Hammond's letter, as given on page 9 last week:

"Sir,—My attention has been called to the letter appearing in your issue of the 3rd inst. respecting the correspondence between Mr. Hammond and the Board of Trade as to granting licenses under the Electric Lighting Acts.

"As my company is the only company in London which has been working under a license from the Board of Trade, I feel it would be unfair to the immediate prospects of electric lighting in the metropolis to allow Mr. Hammond's attack on the industry to remain unanswered.

"The chief point to which I desire to call your attention is the inaccuracy of Mr. Hammond's suggestion that no district lighting has yet been so satisfactory in the metropolis as to warrant the apportionment of the metropolitan area by means of provisional orders, and that no district lighting whatever has been carried out over an extended area by means of underground mains. My company, or rather the Kensington Court Electric Lighting Company, by which name the company was known before extension, has been supplying the electric light to residences in the vicinity of Kensington Court for the last two years. Throughout the whole of that time there has only been one partial stoppage and lowering of the illuminating power, which lasted for less than one hour and a half (between 4 and 6 p.m.,) and occurred at a time when necessary changes were being made with a view to the extension of the supply. With this single exception the light has been supplied by meter throughout the whole period in question day and night without intermission, and with the same regularity as gas.

"Moreover, the mains of my company are laid entirely underground, in pursuance of powers granted to them by the Board of Trade with the consent of the local authorities. I submit, therefore, that the experience of my company is sufficient to show that the time has now come when provisional orders may be granted with due regard to the interest of the public, and I would point out, moreover, that it cannot be expected that the light will be supplied on any greatly increased scale except under the protection which a provisional order alone can give.

"It is for this reason that my company are now applying for a provisional order in Kensington and Knightsbridge, and I am surprised that Mr. Hammond should put forward reasons against the granting of provisional orders, seeing that the House-to-House Company, which he represents, is making a similar application. I trust that Mr. Hammond's company, when they start supplying electricity, may prove that the system adopted is worthy of public support, but that in the meantime nothing will be done to check the advance which, after so long a delay, has been brought about in the electric lighting of the metropolis.—I am, your obedient servant,

"R. S. ERSKINE, secretary Kensington
"and Knightsbridge Electric Lighting
"Company, Limited,

"Kensington High-street, London, W., January 5."

"Sir,—A day or so since a letter was addressed to you by Mr. Robert Hammond, of the House-to-House Electric Light Supply Company, on the question of giving permanent tenure to undertakers for supplying metropolitan areas.

"I will not trouble you with regard to Mr. Hammond's correspondence with the Board of Trade; the accuracy of the statement which I made on December 21 as to the decision come to by that department is sufficiently shown by the paragraph, apparently communicated officially, which appeared in most of the London papers on the 2nd inst.

"The remainder of Mr. Hammond's letter is a series of arguments in favour of procedure by way of license as against provisional orders, and yet I see in the *London Gazette* of November 23, 1888, the advertisement by his company of their intention to apply to Parliament for a provisional order; consequently his conversion to the other method must be of recent date.

"I will take his arguments in order:

"1. He says that no district lighting has been done by underground mains so as to warrant the granting of provisional orders.

"True, with the exception of the Kensington Court Company, those who have been in possession of licenses or orders in the metropolis, Mr. Hammond among them, have done nothing whatever underground or overhead, and it could only have been done by them, as those not under the Act were unable to place mains underground. On the other hand, great attention has been paid for some years past to the distribution of current by means of overhead conductors, so as to combine with economy the *maximum* security against all dangers. I think I may claim that the experience thus gained will render underground work comparatively easy.

"2. He says that it is against the interests of the public to be served by companies who are unable to carry on the work; and till the new companies have proved by natural selection which is the fittest, no provisional order should be granted.

"To the first portion of this there is no objection, but I submit that the weeding out of the new companies by natural selection will cause no greater inconvenience to the public under provisional order than would arise were they only licensed. Again, the safeguards which have been provided by Parliament and by the conditions the Board of Trade prescribe, amply protect the public against any serious disadvantage arising from incapacity on the part of the undertakers under an order. Directly it is found that the company holding the order is incapable of adequately discharging the obligations arising thereunder, the Board of Trade can revoke the order, and, moreover, grant concurrent orders to other companies. It has been expressly enacted that a provisional order shall confer no monopoly upon the company that holds it, and my company in all their communications with the local authorities of London and the Board of Trade on the subject have intimated their perfect willingness that whatever orders may be granted to them, equal and concurrent powers may, so far as we are concerned, be granted to any other companies over the same areas. I affirm, therefore, with confidence that any disadvantage which may result to the public from the granting of a provisional order to a company not thoroughly able to carry out its work will be temporary in its nature, and slight in comparison with the disadvantage which will ensue if the Board of Trade should adopt the mistaken policy of declining to grant any orders at all until some company has proved its capabilities to demonstration.

"3. On Mr. Hammond's third argument I have no special remark to make, as I think that in most cases it would be correct, subject always to the qualification laid down at the close of this letter.

"4. His fourth reason contains the statement of the fact that two companies gave notice of applying for provisional orders in June last for large areas of the metropolis (his own company did the same in respect of a considerable district in the West End). He goes on to say that if these companies attain their desires, the knowledge and experience of other companies would be excluded.

"Speaking for my own company, I can only assure Mr. Hammond that I have no desire whatever to exclude his or any other company, that I entirely disavow any wish for monopoly, such as he seems to seek for himself, and that all I hope for is a fair field to show what can be done. If the companies he refers to do their work well

the public will get the light more cheaply than if the work were being done by a large number of small companies. If they do not do their work well, other companies can and will come in to compete with them—in either case the public interest is protected.

"5. What is said about the county councils is a matter so entirely within the discretion of the Board of Trade that I merely allude to it to say that I do not think the suggestion a wise one.

"But, sir, there is a point which Mr. Hammond has overlooked, and that of predominating importance—namely, the impossibility of raising the necessary capital under such conditions as he indicates.

"It was the unanimous testimony of every representative of the trade, and of nearly all the other witnesses who were examined on the subject by the Lords' Committee appointed in 1886 to consider the working of the Act of 1882, that the principal cause which retarded the development of electric lighting in England, and caused this country to stand so far behind the United States in that respect, was the unduly short tenure granted to undertakers by a provisional order framed in accordance with the Act of 1882. The justice of this view was recognised by Parliament, which, during last Session, amended the Act by extending the period from 21 to 42 years.

"The effect of this step is shown at once in the revived activity which now exists, and in the fact that numerous provisional orders are being applied for in the metropolis and elsewhere.

"I cannot understand how any gentleman professing to speak as an authority upon the electric lighting question can possibly advocate other views; and yet Mr. Hammond now asks the public to believe that, so far from 21 years being insufficient, the industry may be expected to work satisfactorily under the seven years' tenure afforded by a license. Feeling sure that I shall carry with me the assent of every other representative of the trade, I conclude by asserting that if the Board of Trade should decide not to grant a longer tenure to electric lighting undertakers than is afforded by a license, the distribution of current in London under Parliamentary authority will be checked as effectively for the future as it has been during the past six years.—I am, sir, your obedient servant, "CRAWFORD.

"London Electric Supply Corporation, Limited,
3, Adelphi-terrace, W.C., Jan. 8."

ELECTRICITY: LIGHT AND POWER.

Mr. Holroyd Smith has contributed an article under this title to the "Corporation Societies' Annual," from which the following extracts are taken. The paper is intended to be a popular exposition for the benefit of those unlearned in the subtleties of electrical science. Some of the statements, it will be seen, are rather of an heterodox order.

So rapid has been the development of the application of electricity to useful purposes, and so great are its possibilities for the future, that we may fairly claim to have entered upon the electric age, and the purport of this paper is to recount some of the work that has been achieved, and to explain the "how" and the "why," avoiding, as far as possible, technical expressions, and where they must of necessity occur, giving their meaning.

The explanations are not intended for those "skilled in the art," but are given in the hope that the first principles of the science may be better understood by the general reader.

What electricity is, it is impossible to say; we do not know, nor shall we ever know. Like the questions, "What is life?" "What is matter?" it must remain unanswered; but, though we do not know what it is, we know many things about it, and are constantly learning more. We can produce and measure it, direct and control it, and make it serve a hundred useful ends.

If electro-biology or animal magnetism be excepted, the old-world sages were apparently ignorant of its existence till about 600 years before Christ, when Thales, of Miletus, discovered the peculiar power of acting upon other light substances manifested by a piece of amber after it had been subjected to rapid friction, and, finding this in nothing else, called the action the same name, "electron," the Greek word for amber. We know now that the same property exists in many other substances—sealing wax, for instance; still, the original name has been preserved and become peculiar to this natural force—so much so that some begrudge its original meaning.

It certainly would sound strange, if the word were interpreted, to hear such expressions as the amber telegraph, the amber belt, the amber line, the amber engineer. It may, like "angel," "minister," or "knave," be taken as an example of how the original meaning of a word may be forgotten in its peculiar and recognised use.

The electron of Thales remained a mysterious and unexplainable symptom until well on into the middle ages, and perhaps the first real use of this subtle agent was the mariner's compass.* Little further progress was made until Franklin drew lightning from the clouds.

To a novice it might seem that there was nothing in common between the attractive and repellant action of a piece of rubbed amber, the northward pointing tendency of a steel needle after it had been rubbed with loadstone, and the vivid flash of blinding light that precedes a thunder clap; yet this is so. They are all attributable to the same cause, that mysterious mode of motion which we call electricity. The great world itself may be regarded as a huge dynamo; and there is truth in the saying, "Electricity is life."

The production of electric action by chemical means is a field of research full of interest and instruction; to trace its origin and development, and the many and varied uses to which it has been applied, would occupy more space than is here available. Perhaps the greatest practical use resulting from it is the electric telegraph—

"The wondrous wire of magic power
To flash glad tidings o'er the boundless sea,
And link far nations close in word and thought."

To chemical electricity we owe the knowledge and experience that has enabled scientists to develop its modern form; whilst we were dependent upon chemical action for the production of an electric current, there remained the unsurmountable obstacle to progress—viz., cost. The one ruling question in this commercial world is, "Will it pay?" and whilst we were dependent upon the decomposition of metals in acids for electric energy all attempts to produce light or power failed, except as experiments, because of the expense. Not until that immutable law, the conservation of energy, was formulated and proved, and the principle turned to the study of electric action, was there any real advance. It is therefore obvious that electricity cannot be studied alone, and it is only to be properly understood by being studied in conjunction with the general principles of chemistry, the laws of motion, energy, force, and heat, the fundamental principles of mechanics; in fact, more than a mere surface acquaintance with those subjects usually grouped under the title of natural philosophy is essential.

It is assumed that the construction and operation of an electric battery is well known. To state it broadly, if two plates of different metals—say one copper and one zinc—are placed in a vessel containing an acid solution, and a metallic connection is made between these two plates, a current of electricity passes; this would constitute a primary battery, the metals and chemicals to be used, their compositions, the form of cell in which they are placed, would form an endless subject—their name is legion. Hardly a week passes but somebody invents (or reinvents) a primary battery; and notwithstanding the comparative completeness of the knowledge of electro-chemical action, it is repeatedly being announced to the world that a new primary battery is discovered that won't wear out, that will produce light and power for nothing, because the elements are so changed in the action as to be worth more when finished with than when new. The "how" is kept a profound secret until a company is formed, and after the money has been subscribed it dies a natural death.

It may be stated that a powerful, safe, and economical primary battery cannot be made until metals and acids become as cheap as coal.

A few years ago a notice appeared in the papers that a Frenchman had travelled from Paris with a small box, and conveyed it safely to Glasgow, where a learned professor of deservedly high repute examined it, and astonished the world by stating that it contained stored electricity capable of developing several hundred horse-power if let loose; a meaning and importance has been attached to the professor's words which he could never have intended, and from them a delusion has become fixed in the popular mind that will be difficult to remove—viz., that electricity can be pumped into a bottle and carried about, and it is only necessary to turn a tap to obtain unlimited energy. Let it be here stated that, strictly speaking, there is no such thing as stored electricity, and that the names, "accumulators," "storage batteries," are misnomers. They should be called "secondary" batteries, and their value and utility consists in the fact that, instead of absorbing chemical and mineral elements in the production of electric currents, dynamic force is absorbed—that is, the power of a steam-engine, water-wheel, etc.—and is given out again as electricity. What takes place may be roughly stated thus: A battery consisting of metals and

* The discovery is generally attributed to Flavis, a Neapolitan, but there are grounds for supposing it was brought to Europe from China, by one Paulus Venetus, an Italian.

Digitized by Google

acids, preferably lead and dilute sulphuric acid, is taken; the acid has no appreciable effect upon the lead if left alone, but if an electric current is passed through (mark—passed through, not made to stop), it so disturbs the acid and the lead that they get angry with one another, the acid divides itself, one element attacks one lead plate and the other element the other lead plate, and the stronger and the longer the passage of the current the greater the disturbance, the plates become changed, their natural condition is altered, and remains so after the exciting current ceases to flow; but those plates want to resume their natural condition. Join them with a copper wire, they seize the opportunity, and in making friends again reproduce electricity.

There is a limit beyond which these lead plates cannot be excited. When they have reached this limit no useful effect is produced, no matter how much longer you continue to pass a current through them. From this follows the fact that if you want a secondary battery to give off much electricity for some time it must be big and heavy, a fact not sufficiently realised, and one that it would be well for all to remember.

It will be seen from the above that, as "secondary batteries" require a current of electricity to form them, they would be of little commercial value were there no cheaper means of producing electricity than by the employment of primary batteries.

The question may therefore be asked, How, then, can electricity be economical at all? and the simple answer is, because it can be made from coal* without the consumption of metals and acids; and as that answer would naturally elicit the further question, How? an attempt will now be made to give an answer.

Electricity has previously been described "as *a* mode of motion"—the indefinite article is there used because there are other "modes of motion" besides electricity. The very definition itself may seem indefinite, and can only be understood by examining the various manifestations of electric modes of motion. Let us look first to the primary source—viz., heat. Heat, potential or latent, may be regarded as the source, and we may call the sun the great primary battery. Electricity can be produced direct from heat in an apparatus known as a thermopile, and that is the widest and most promising field for further investigation and future development; but inasmuch as we have to remember "will it pay?" they are disregarded here because their present efficiency is too low for them to be of commercial value.

Keeping in view the axiom that heat is the prime source of electricity, let us briefly examine some of its phenomena.

Take an ordinary primary battery with a zinc plate and a copper plate, and couple the terminals by an iron wire. The solution will begin to fume and bubble and boil, and the iron wire will become hot. The passage of the electric current manifests itself by the production of heat. If the battery is strong enough, the wire will become red, then white-hot, and fuse away.

This is the principle of all electric light—viz., the passage of an electric current producing heat. If the battery and the wire were well arranged, little heat would be produced in the battery and intense heat in the wire. It is popularly supposed that the electric light is cold. This is an error; the coldest-looking light is the hottest. It is the very intensity of the heat of the arc lamp that produces the blue-white glare. There is nothing hotter. That small bead of light between the two points of the carbon rods is eight times hotter than molten iron. The little wiry-looking thread in the glow lamp gives out light because of the heat produced in it by the passage of electricity. Were it not in the glass globe, from which all the air has practically been exhausted, it would be instantly burnt away. Without pursuing this investigation further, we see that electricity produces heat, and that heat can be made to produce electricity.

Let us now look for manifestations of electricity other than heat (we can find none without).

If, instead of coupling the terminals of the battery by a piece of iron wire, we had taken a piece of copper wire covered with cotton or silk (for anything that is a bad conductor of heat is a bad conductor of electricity), and had wound it round a bar of iron, we should find that the passage of a current of electricity round and round the iron would make it magnetic—that is, capable of attracting and holding other pieces of iron. If we wind another piece of wire round the same bar, but instead of coupling its ends to the battery we couple them to an instrument so constructed that it will indicate when a current is passing, then if we continue lifting and replacing the zinc plate in and out of the solution, we shall find that the instrument indicates the passage of electricity through the wire that has no connection with the battery at all, but simply wound alongside the battery wire. Again, suppose we coil the battery wire round a paper tube and allow the current to continue to flow through it, and wind the instrument wire round an iron bar small enough to pass into the paper tube, and drop it in and pull it out, we shall find that each time we do so the instrument will indicate the passage of a current.

Take a plain bar of iron, and slowly insert one end into the coil, it will be immediately sucked in and held there as long as the battery current flows through the wire. If the bar were steel instead of iron, and were allowed to be sucked in at one end of the coil and forcibly withdrawn at the other or opposite end, and the process repeated a few times, the steel bar would not only be a magnet whilst in the coil, but would remain one after it was removed, and be able to attract and hold pieces of iron, although there was no battery sending a current of electricity round it.

If, now, we took the steel magnet, and the bar of soft iron previously mentioned, with the coil of copper wire wound round it, having its ends attached to the indicating instrument, and approached one end near enough to the steel magnet to feel the pull and suddenly withdrew it—that is, waved it to and fro past the end without allowing it to touch—we should find that the instrument would indicate the passage of an electric current through the copper wire, and the nearer it came and the faster it moved the stronger would be the indication.

The above may seem simple experiments and not of much practical use, but they are the A B C of electrical engineering, and if fully mastered and realised will be found to be the foundation upon which much modern work is built; but there is one other simple experiment which has been attended with such important results that it deserves especial notice. All iron is slightly magnetic, all iron will become strongly magnetic if a current of electricity passes round it; so instead of using the steel permanent magnet, take two bars of iron, each with a coil wound round it, join one end of each coil by a flexible wire and connect the other ends to the instrument and repeat the waving process, but more rapidly, and it will be found that the instrument again indicates a current. The slight magnetism in the iron has caused a slight current in the wire, and the slight current in the wire passing round the stationary bar increases the magnetism of the iron, the increased magnetism strengthens the current, and so one acts upon the other. The stronger the magnetism the stronger the current, and the stronger the current the stronger the magnetism; and if these went on increasing, the force would become so strong as to burn up the copper wire: this has been done.

The foregoing experiments have been given in their simplest condition, without describing what constitutes the best form of magnets, or how copper discs or coils of wire can in some cases be substituted for the iron bars, or how and why the copper wire has to be insulated, etc.

They are, however, sufficient to show some of the essential facts which are at the service of all who will learn how to use them—the hammer, the vice, the file, and the chisel of the electrical workshop—and it only needs the spirit of adaptation to render them useful. Just one example. It would evidently be fatiguing to continue waving the iron bar with a coil round it to and fro in front of a magnet, and it would naturally suggest itself to a mechanical mind that this bar, and others like it, could be attached to the surface of a wheel, and by rapidly rotating the wheel they could be rapidly made to traverse across the face of the magnet, or, to use a technical expression, made to cut the lines of force in the magnetic field. And, further, when by this wheel a small quantity of electricity is obtained, say sufficient to light one small lamp, it will be easily seen that by making a larger machine and employing a steam-engine to turn it, large quantities of electricity can be obtained without using any battery at all; and, it may be asked, "Is not electricity the transformation of transmitted energy?"

Some other facts are necessary to be known and understood before we can attempt to make practical use of those already given. Perhaps that which is manifest in the mariner's compass is the most important—viz., the north-seeking tendency of one end, and the south-seeking tendency of the other.

It does not follow from this that all "dynamos" or electric instruments must be so placed relative to the earth's axis as to accommodate to the north and south, but another result of this tendency is of the highest importance—namely, that the N. (or north) pole of one magnet attracts the S. (or south) pole of another; but the N. pole repels another N. pole, likewise an S. pole repels another S. pole. This may be shortly expressed by saying opposite poles attract and similar poles repel each other.

If, therefore, two magnets are taken and are held a distance apart, with opposite poles facing each other, and a plain iron bar free to swing upon a pivot be placed between them, and at right angles to them, it will at once swing until it lies in a line with the magnets, and it does not matter which end of the plain iron bar turns to the north or south of the magnet; but if the plain iron bar be removed and a steel bar that has been made into a permanent magnet be substituted, and it be so held that the north of the steel magnet faces the north of the main magnet, if released, it at once swings round and points to south, whilst the end south has also swung to north, and if the magnets are large it will require considerable force to twist them away.

Now, if the order were reversed, and an electromagnet were used in the middle to swing round between the poles of a permanent magnet and it be rapidly turned by any convenient means, it would constitute a magneto-electric machine. The revolving part is technically known as the armature.

* The latent energy of a pound of coal is 12 times greater than the latent energy of a pound of zinc, whilst a pound of zinc costs 20 times as much as a pound of coal.

Digitized by Google

It would be entering too much into detail to explain how the ends of the wires would have to be coupled and compensation made for the fact of rotation; sufficient to say that this is accomplished, and the parts fulfilling the object are called "commutators" and "brushes."

Just go a step further. Remove the stationary steel magnet, and in its place put bars of soft iron with wire wound round it, and, taking advantage of the commutators and brushes, allow the current produced by the revolutions of the armature to flow round the wires of the stationary magnets as well as going to the outside work (lamps, etc.), then the machine becomes an electric generator, now generally known as a "dynamo."

From what has been said before it will be seen that a machine built on this principle has only to be made to revolve rapidly to produce electric currents, and, what is equally important, it is only necessary to allow an electric current to flow into the machine to cause it to revolve and make it into an electric motor; why this is needs a little further explanation (although the underlying facts have been previously stated).

(*To be continued.*)

COMPANIES' MEETINGS.

PILSEN, JOEL, AND GENERAL ELECTRIC LIGHT COMPANY.

An extraordinary general meeting of the Pilsen, Joel, and General Electric Light Company, Limited, was held on January 4 at the City Terminus Hotel to consider a resolution voting £100 each to Messrs. H. W. Scriven and G. L. Whately in respect of their services as Directors of the Company from December 11, 1886, to March 13, 1888, and also the confirmation of the resolutions passed at the meeting on the 14th ult., (1) for winding up the Company voluntarily; and (2) for appointing Mr. George Shead and Mr. W. H. Trentham joint liquidators.

Sir R. W. Rawson, who presided, stated that when at a former meeting it was found that, through an oversight (the nominal value of the shares having been reduced), Mr. Sciiven and Mr. Whately had ceased to be qualified, they at once refunded the money they had received as Directors. He expressed a hope at the time that the amount in question would be returned to them, and their largest shareholder had now proposed that that should be done.

Mr. Gwynne then moved, and the **Chairman** seconded, a resolution voting the payment of the sum named to Mr. Scriven and Mr. Whately.

Mr. Fyfe and other shareholders objected on various grounds to the payment, and the Directors were charged with gross mismanagement.

On a show of hands being taken, the resolution was declared lost—five voting for it and six against it. A poll was demanded, and at once taken, when it was announced by the scrutineer that the number of votes recorded against the motion was 1,010, and in favour of it 8,102.

The **Chairman** then duly declared the resolution carried. He afterwards proposed the confirmation of the resolution for winding up the Company voluntarily.

Mr. Hutton moved and **Mr. Blecklehurst** seconded an amendment adding to the resolution the words "under the supervision of the Court."

The **Chairman** stated that the alteration ought to have been made at the first meeting, and that the resolution must now be either rejected or carried. He then put the motion, and declared it carried by nine to four.

The resolution confirming the appointment as liquidators of Mr. Shead and Mr. Trentham was afterwards agreed to by seven to four.

MAXIM-WESTON ELECTRIC COMPANY.

An extraordinary general meeting of the Maxim-Weston Electric Company, Limited, was held on January 7 at the Cannon-street Hotel, for the purpose of confirming the resolutions passed at the extraordinary general meeting held on December 21 last. Mr. John Marks occupied the chair.

Mr. Samuel J. Boyce (the secretary) read the notice convening the meeting.

The **Chairman:** Gentlemen, in moving the confirmation of the resolution just read by the Secretary, I will draw your attention to one clause in the agreement which was read fully at the last meeting —every word was read fully at the last meeting, therefore I presume you know its contents. One clause provides that the new company have the power, by giving notice to the liquidators, to terminate the agreement if dissentient shareholders, or shareholders holding 30,000 shares, dissent from the reconstruction scheme. Well, now we know that great efforts are being made in certain quarters to induce shareholders to dissent from the reconstruction scheme, and those efforts are being made from interested motives. Mr. Abrahams at the last meeting told us that he represented shareholders holding 30,000 shares, and he should certainly dissent from the scheme. If shareholders holding 30,000 shares only dissent, I do not think that would be a bar to the new company carrying out this agreement with the liquidators; but if a very large number of shareholders dissent, I think then the new company would be justified in not carrying out the agreement, because, to satisfy the gentlemen who dissented, the money of those who took up new shares would have to be applied, and that would not be fair. I merely make these remarks to point out to you it is contrary to your interest to dissent from the scheme. It is all very well for Mr. Abrahams to tell us the liquidators will give 2s. a share to each dissentient. That is held out for the purpose of inducing you to dissent. We have a very different opinion. I think if they get 3d. or 4d. a share they will be lucky. Therefore don't be deluded into the belief you will get 2s. a share by dissenting. It is merely placed before you for the purpose of damaging the Company. I am sorry Mr. Abrahams is not heie. I wanted to tell him, as representative of Mr. Hugh Watt, even if the scheme does not go through—and I cannot believe the shareholders will be so blind to their own interest as not to carry the scheme out—whatever is the result, the matters between this Company and Mr. Watt, even if this Company falls into the hands of the liquidators to be dealt with finally —the matters at issue between Mr. Watt and the Company will be carried out by the liquidators just as if the new company was formed. I now formally move the confirmation of the following resolutions—viz.: "(1) That the liquidators of the Company be, and they are hereby, authorised to consent to the registration of a new company, to be named the Maxim-Weston Electric Company, Limited, with a memorandum and articles of association which have already been prepared with the approval of the Directors of this Company. (2) That the draft agreement submitted to this meeting, and expressed to be made between this Company and its liquidators of the one part, and the Maxim-Weston Electric Company, Limited, of the other part, be, and the same is hereby approved, and that the said liquidators be, and they are hereby authorised pursuant to Section 161 of the Companies Act, 1862, to enter into an agreement with such new company (when incorporated) in the terms of the said draft, and to carry the same into effect with such, if any, modifications as they think expedient." The agreement is here and open to the inspection of anyone who wishes to see it, and with your permission I will take it as read. It is a long document, and any gentleman who wishes to see it can do so.

Mr. Swaby: I beg to second the motion, and I think I ought to say a few words. Several shareholders have begged that, if the scheme failed, we would endeavour in other ways to carry the company through. They are poor shareholders, and ask us to do all in our power. I must say the Board has worked hard in your interest, and in your interest alone.

Mr. Klenck: I may point out that this is our final scheme, and if you do not accept it the consequence will be the Company will go into liquidation, and then you know the result—the selling of our patents and machinery, and everything we possess, and that will only give you a very small distribution. I think our Chairman has taken a rather gloomy view of the situation. A threat is one thing, and a fact is another. We hold these proxies from the shareholders who have sent us their support. We have not a single opposition in the office, and I think that ought to be known to the shareholders generally, so that they may not follow in the footsteps of those who have interested motives in asking them to dissent from the scheme. If you are wise you will come into the scheme, and we shall be able in a very short time to put the Maxim-Weston on a sound commercial basis, a position we have not occupied for some considerable time in the past, so that we may be able to take orders and execute them for the benefit of the shareholders.

The resolution was then put and carried.

The **Chairman:** The forms of application for shares will be sent out in due course to each shareholder, and, as Mr. Klenck says, I hope we shall find the shareholders support us in the same manner as they have done in sending in their proxies.

A **Shareholder:** I would suggest that when the forms are sent out, a report of this meeting should be sent in order to show shareholders what their position will be if they dissent. Probably many may dissent, thinking they will get 2s. a share. They should understand that they will more probably get 2d.

The **Chairman:** I think that this is a very good suggestion, to send out a *résumé* of what has taken place, and that we will do.

Mr. Klenck stated that the number of shares held by the dissentients amounted altogether only to 50 shares.

The proceedings then terminated.

METROPOLITAN ELECTRIC SUPPLY COMPANY.

An extraordinary general meeting of the Metropolitan Electric Supply Company, Limited, was held on Tuesday, for the purpose of considering resolutions in accordance with the requirements of the Committee of the Stock Exchange altering the articles of association of the Company. Alderman Sir R. N. Fowler, M.P., occupied the chair.

Mr. E. Cunliffe-Owen (the Secretary) having read the notice convening the meeting,

The **Chairman** said: These alterations were required by the Committee of the Stock Exchange. They were merely for the purpose of carrying out the stipulations of the Stock Exchange, and he would ask Mr. Burt to explain their purport.

Mr. Burt: Article 26 is the first of the proposed alterations. The article says: "The share qualification of a Director shall consist of his being a registered holder of 200 shares. A Director may not act before acquiring his qualification." The Stock Exchange require these latter words to be struck out. The point is of no importance whatever in this Company, because the Directors have long since acquired their qualification. Article 45 is a limitation of the powers of borrowing of the Company, which is also one of the new requirements of the Stock Exchange. Probably shareholders will think it reasonable. It is a recent requirement, by which in all cases they ask that powers of borrowing should be limited to some extent by the articles of association. Article 45 was drawn in the old form without restriction, and it is proposed to add the words which are, in fact, a limitation to the amount of the share capital at the time being of the Company. Article

Digitized by Google

102 is also one which is a modern requirement of the committee. It stood thus: "A Director shall not be appointed auditor"; they ask it shall be altered: "No Director or other officer of the Company shall be appointed auditor." Of course, there was no intention of appointing anyone who is an officer. Article 119 restricts the lien on the shares to those which are fully paid. In Article 121 there is an alteration which provides that the transfer of shares shall be in the usual common form. In Article 123 they desire to insert the words "not fully paid up." "Transfer of shares shall not be made to any person who shall not be approved by the Board." The addition is, "not fully paid up"; so that a transfer may be made to any person if the shares are fully paid up. If they are not fully paid up, it is necessary the board should have discretion, otherwise, if any company were in difficulties, and there was a sum unpaid on the shares, the holder of the shares might transfer them to a man of straw to escape his liability. In Article 130, which says, "Every original shareholder shall, on the original issue of the shares, be entitled to one certificate for each of his shares granted to him, but in every other case 1s. shall be paid," they require some alteration which is not of the slightest importance. In Article 155 the words come in again about not being fully paid up, and that applies to the lien also. It appears to be pretty much the same as in the previous clause. These are the only alterations. I think it will be convenient to take the resolutions *en bloc*.

The **Chairman:** Then I beg to move the following resolutions: "That the articles of association of the Company be altered as follows: Article 26—By striking out the words 'A Director may act before acquiring his qualification.' Article 45—By adding at the end of this article the words 'Provided that the power of borrowing and raising money, and of making and issuing mortgages, or debentures, or debenture stock, obligations or other securities, shall not at any time, without the sanction of a general meeting, be exercised to such an extent that the total amount of principal money borrowed, raised, or secured shall exceed the nominal amount of the share capital for the time being; but this restriction shall not oblige any person taking any mortgage, or debenture, or debenture stock, obligation, or other security of the Company, to inquire whether there has been any such excess, or affect the validity of any such security in the hands of a bona fide holder, nor interfere with the power of the Directors to make and enforce calls.' Article 102—By striking out the words, 'A Director shall not be appointed auditor,' and inserting in lieu thereof the words, 'No Director or other officer of the Company shall be appointed auditor.' Article 119—By inserting after the word, 'shares' the words, 'not fully paid.' Article 121—By inserting after the word 'writing,' the words 'which may be in the usual common form.' Article 123—By inserting after the word 'share' the words 'not fully paid up.' Article 130—By striking out all the words except the words 'every shareholder shall be entitled to one certificate for his shares gratis, but in every other case one shilling shall, where the Board think fit, be paid to the Company for every certificate.' Article 155—By inserting after the word 'shares,' in line 2, the words 'not fully paid up.'"

Sir James Anderson seconded the motion, which was carried unanimously.

A vote of thanks to the Chairman and Directors then terminated the proceedings.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts for the past week amounted to £3,755.

Direct Spanish Telegraph Company.—The estimated receipts for December were £1,908 against £2,004.

Great Northern Telegraph Company.—The receipts of this Company for the month of December amounted to £22,000.

West Coast of America Telegraph Company.—The receipts for the month of December amounted to £4,475.

Eastern Telegraph Company.—The receipts of this Company for December were £59,834, as against £57,703 for the same period of 1887, or an increase of £2,131.

Eastern Extension Telegraph Company.—The receipts of this Company for the month of December were £38,699, as against £38,908 for the same period of 1887.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting the "fifth" payable to the London Platino-Brazilian Company, were £3,228.

United River Plate Telephone Company, Limited.—This Company have declared an interim dividend, for the half-year ending September 30 last, of 3 per cent. (being 3s. per share), tax free, payable on and after the 15th inst.

Edison and Swan United Electric Light Company, Limited. Owing to Victoria-street, Westminster, having been renumbered, in future the address of the Edison and Swan United Electric Light Company will be 100, Victoria-street.

Companies of the Month.—The following electrical companies have been registered during the month:—

British Electric Tramways and General Syndicate, £5 shares £10,000
Electropathic and Turkish Baths, £1 shares 10,000

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during September was 4,323, estimated to produce £3,500, against 3,925 messages, producing £3,373. The receipts for September, estimated at £2,700, realised £2,774. It is announced that the offices of the Company have been removed to 58, Old Broad-street, E.C.

NEW COMPANIES REGISTERED.

E. Page and Company, Limited.—Registered by Crossman and Pritchard, 16, Theobald's-road, Gray's-inn, London, W.C. Capital £30,000 divided into 30,000 shares of £1 each. Object: to carry on the business of an agricultural, mechanical marine, electrical engineer, and of an iron and brassfounder and ironmonger in all its branches. To acquire the business now carried on by James Woodward Hill, trading as E. Page and Company, at Bedford, in the county of Bedford, and to carry on the same in all its branches. The first subscribers are:

	Shares.
L. Hely, 40, Montpelier-street, Knightsbridge, London, S.W.	50
B. H. C. Caxton, Margett's-road, Kempston	50
F. H. Hill, 22, Kimbolton-road, Bedford	50
F. Fisher, 14, Castle-road, Bedford	50
E. D. Rabbitt, 21, Grove-place, Bedford	50
J. H. Darlow, 1, Horne-lane, Bedford	50
J. W. Hill, 22, Kimbolton-road, Bedford	29,700

There shall not be less than four nor more than six Directors of the Company, and no person shall be a Director unless he holds at least 50 shares in the capital of the Company. The first Directors shall be James W. Hill, B. H. Claxton, E. D. Rabbitt, J. H. Darlow, and E. Fisher. The first Directors shall be paid the sum of £50 per annum each, with an additional sum of £50 to the Chairman.

PROVISIONAL PATENTS, 1889.

JANUARY 1.

30. **Improvements relating to electric telegraphy.** Mark Wesley Dewey, 45, Southampton-buildings, London. (Complete specification.)

46. **An improved atmospheric thermo electric generator.** William Scarlett de Lisle Roberts and James Smith Mollison, 6, Bream's-buildings, Chancery-lane, London, W.C. (Complete specification.)

JANUARY 2.

85. **Improvements in dynamo electric machines.** Arcadius Poleschko, 24, Southampton-buildings, London, W.C.

JANUARY 3.

112. **A railway distant electric flashing signal.** James Woods and Henry William Hatfield, 54, Winchester-street, Caledonian-road, N.

118. **Improvements in electric brakes for railway trains.** Watson Playtor Widdifield and Alexander Hamilton Bowman, New Bridge-street, Manchester. (Complete specification.)

126. **An improvement in or relating to dynamos.** Gilbert Bettley Lückhoff, 166, Fleet-street, London.

135. **Improvements in the arrangements for lighting and, or, braking railway vehicles electrically.** Illius Augustus Timmis, 2, Great George-street, Westminster, S.W.

JANUARY 4.

179. **Improvement in the use of incandescent electric lights.** Charles Wells, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex.

189. **Improvements in armature winding for dynamoelectric machines.** Walter Harris Knight, 23, Southampton-buildings, Middlesex. (Complete specification.) (Date applied for under Section 103 of the Patents, &c., Act, 1883, 6th June, 1888, being date of application in the United States.)

JANUARY 5.

238. **Improvements in alternate current dynamo electric machines.** John Dixon Gibbs and Emile Fesquet, 47 Lincoln's-inn-fields, London.

SPECIFICATIONS PUBLISHED.

1888.

242. **Electrical measuring instruments.** Davies. 8d.
366. **Electric arc lamps.** Abel. (Siemens and Halske.) 8d.
1525. **Distributing electricity.** Solignac. 8d.
2449. **Electric railways.** Allen. 8d.
13,529. **Electric meters.** Reckenzaun. 8d.
14,919. **Electrical brake, &c.** Hutchinson. 8d.

NOTES.

"Electric Power."—A new journal specially devoted to electric motor work of all kinds has just been started in New York, under the title of *Electric Power.*

Removal.—Mr. A. A. Campbell Swinton has removed his offices to 66, Victoria-street, Westminster, where all communications should now be addressed to him.

The Heisler System.—There are 40 towns using 16,465 lamps of 30 c.p. on the Heisler long-distance incandescent system in the States at the present time.

Obituary.—The death is announced of Sir William O'Shaughnessy Brooke, late Director-General of Telegraphs in India, at Southsea, in the 80th year of his age.

The Julien System.—The three Julien cars on the New York line have run 125 car-days, giving a run of a total of 3,913 miles, and carrying 35,066 passengers.

Brockie-Pell Arc Lamps.—Messrs. Johnson and Phillips report a sale of 600 Brockie-Pell arc lamps during last year. The lamps have gone to all parts of the world.

City Lighting.—A resolution passed at the Aldgate wardmote in favour of electric lighting has been referred to the Streets Committee of the Commissioners of Sewers.

Society of Arts.—A paper will be read at the Society of Arts on Wednesday next, January 23, at 8 p.m., on "Electric Meters for Central Stations," by Prof. George Forbes, F.R.S.E. Mr. W. H. Preece, F.R.S., will preside.

Delaney's Cable Apparatus.—Mr. P. B. Delaney has received advices to the effect that the German Government has purchased a set of his cable instruments for use on their long underground circuits, upon which the system has been undergoing trial for several months.

The Electric Light at Leamington.—The Leamington Town Council has resolved to give the Midland Electric Light Company 12 months' notice to determine a contract for lighting the streets of Leamington by electricity, on the ground that it had been a failure.

Electric Sugar.—Warrants for the apprehension of the proprietors of the electric sugar fraud cannot be obtained in America. So reluctant are the shareholders to have their connection with the company brought before the public, that they have decided not to take action.

Bank Lighting.—We are glad to see electric lighting in the City banks is becoming quite general. The London Joint Stock Bank, one of the most conservative of City concerns, which has long held out against the innovation, has at last given in its adherence, and is to be lighted by electricity.

Institution of Electrical Engineers.—The next meeting of the institution will take place at 25, Great George-street, Westminster, on Thursday, January 24, at 8 p.m., when Prof. Andrew Jamieson, F.R.S.E., will read a paper on "The Insulation Resistance of Electric Light Installations."

Theatre Burnt.—Another theatre is burnt, due to the use of gas. On the 29th December the municipal theatre of Novgorod was burnt to the ground, the fire resulting from an explosion of gas. Two persons were killed, and more than thirty injured. Electric light will probably be now installed.

The Julien-Sellon Controversy.—The assignees of Sellon, the Electric Accumulator Company of New York, have insisted that the addition of mercury to the antimony and lead in the plates did not constitute a new invention, but the advantage of the triple alloy in decreasing resistance has been acknowledged by the primary examiner as a distinct invention, and the patent is upheld.

Rome.—The Baudot duplex apparatus has been working for three months on the line between Rome and Turin, before worked with Wheatstone instruments. The Baudot quadruplex will be installed during January on the Rome-Milan line. The chamber of representatives and the senate at Rome are lighted with Edison lamps supplied from the dynamos run by the Rome Gas Company.

Holborn.—At the last meeting of the Holborn Vestry a resolution was carried that the Board do present a petition against and oppose the London Central Subway Railway Bill. A letter was received from the London Electric Supply Corporation, asking the Board's assent to the granting of a provisional order. The communication was referred to the Committee of Works for consideration and report.

Fair Play to Barnet.—We have got to hear that the *Electrician* sent down a special commissioner to Barnet to find out all about the electric light, and report upon the lamps, cut-outs, and general installation. The result happened to be favourable, and the report promptly went into the waste paper basket, a remark simply appearing in the year's summary that the light is not yet satisfactory. How's this, Mr. Editor?

Electric Mining.—By the last mail the Humboldt Electric Power and Mining Company received the survey of the water site, with particulars of fall and quantity of water, both of which are up to estimate, and the distance from the mines is rather less than anticipated. Negotiations are now in progress for the erection of the necessary machinery; the first installation of electric power will be made to the present Esmeralda mill.

Desiderata.—A gold medal has been offered by the Société Industrielle d'Amiens, France, among other things, for the following: A dynamometer of more convenient installation than the Prony brake; a cheap and simple dynamometer capable of measuring the power absorbed by a belt-driven or geared machine tool; apparatus for purifying boiler feed water: the best arrangement for electrically lighting works at less cost than by gas.

Galway.—Tenders are invited by the Galway Town Improvement Committee for the public lighting of the town by gas, electricity, or other approved illuminant. It is expected that electricity will be approved. Specifications can be obtained of Mr. J. Redington, Town Commissioners' Office, Galway. Sealed tenders to be sent in by 7th March. Galway at present is not half lighted, and it ought to be known before tendering whether the specification provides for sufficient light.

Magnetism and Electromotive Force of Batteries.—*L'Electricien* of 22nd December has a note upon the effect of powerful magnetic fields on the E.M.F. of batteries. Figures are given showing the variation (we suppose an increase) in E.M.F. of from 0·0008 volts with a field of 2,000 C.G.S. units to 0·0680 with a field of 19,700 units. A platinum-iron-chromic acid battery was used. The effects are feeble, and delicate instruments are necessary to detect them.

Digitized by Google

Austrian Patents.—In consequence of a recent decision of the Austrian Patent Department, the grant of Austrian patents can henceforth be delayed by applying for it. This alteration in the practice has been adopted with a view to offer the applicants for Austrian patents who have also applied for U.S. patents the utmost security with reference to the uncurtailed duration of the latter, as the grant of the Austrian patent can in such cases be delayed until after the grant of the U.S. patent.

Automatic Supply.—We alluded lately to the possible use in the future for an automatic box arrangement for electric light supply, similar to that proposed for extending the supply of gas to small customers. We notice that a patent has been taken out for such an apparatus by D. H. Davies, of Leeds, and J. M. Tourtel, of Westminster, specially designed for use in railway carriages, but applicable also to other purposes, whereby a passenger or person can obtain an electric light for a given length of time by inserting a coin, and can continue the light by successively contributing coins.

Oil Filter.—An oil filter has been brought out for long running machinery, and is in use in electric light installations for cleaning the used oil. The outer vessel is of glass, through which the action can be inspected; several layers of filtering material—woollen cloths, etc.—are arranged in this, the last layer being at the top. The filter is partly filled with water, and the oil being admitted at the bottom, rises upwards, while the metallic particles fall to the bottom, the drop fall of the oil being broken by the capillary action of the wool, and the clear oil is drawn off at the top.

Electric Locomotive.—An electrical locomotive is building at the New York Locomotive Works, in Rome, N.Y. The engine, says the New York *Electrical Review*, is to be operated solely by electricity, and is designed to run on all roads where steam is now used. It will weigh 15 tons, and when turned out of the shop will be an exact counterpart of an ordinary locomotive, though considerably smaller and lighter. When finished, an electrician from New York will take charge of it, and place in it the electrical apparatus to be used as a motive power. The inventor is W. H. Darling, of Brooklyn.

House of Commons.—The electric light will soon be fitted throughout the House of Commons. Parts of the building have been lighted for some time, including the division lobbies and upper corridors, library, reading-room, tearoom, smokeroom, and a few other rooms, but when Parliament reassembles the cloakrooms, entrance lobbies, and main staircase, etc., will also be lighted. It is understood that the complete adoption of electric light in the House is shortly to follow, and the committee-rooms, the corridors, waiting-halls, and members' lobby, now lighted either by oil or gas, will all be fitted with electric light.

Sulphur as Insulation.—In connection with the high-tension work in progress at Deptford, where it is well known that compounds of sulphur are used for insulation, some experiments of Mr. James Monckman, D.Sc., on the electrical properties of this substance will be interesting. The specific resistance of sulphur was found to be very high, reaching $5{\cdot}6 \times 10^5$ ohms at 440 deg.C., its boiling temperature. At 260deg.C. it is 5×10^8 ohms, these figures referring to chemically pure sulphur. The commercial material has a much smaller resistance, being only $1{\cdot}6 \times 10^5$ ohms at 440deg.C., and 5×10^3 ohms at 125deg.C., its melting point.

The Tesla Motor.—The first exhibition in public of the celebrated Tesla motor took place at the meeting of the City and Guilds Old Students' Association on Wednesday last on the occasion of Mr. Snell's paper, reported elsewhere. The motor in question is a small model, eight or nine inches square, and has never run yet in this country at least, the necessary alternating currents not being obtainable. In has four terminals, and no brushes whatever, the armature simply turning in the varying magnetic field. This specimen was to have been exhibited by Prof. Ayrton at the Bath meeting of the British Association, but did not arrive in time.

Edison Philadelphia Station.—The new Edison electric light station in Philadelphia will soon be in operation. It is six stories high, and was erected at a cost of £30,000. On the first floor will be placed 20 engines of 250 h.p. each. On the second floor there will be 40 dynamos, with a total capacity of 60,000 lights. The third floor will be used for the workshop; the fourth floor for 10 boilers of 500 h.p. each. The fifth floor will accommodate 1,000 tons of coal, which will be fed by pipes to the furnace under each boiler. The sixth floor will be devoted to the general offices of the company. The total cost will be £200,000, including 84 miles of underground cable.

Electric Duel.—The discussion about the danger of alternate current has reached an amusing pitch in New York. Harold P. Brown has challenged Westinghouse to an electric duel; Harold P. to be connected to a direct current machine and Westinghouse to an alternate. Fighting to commence at 100 volts, raising by 50 volts, and maintained for five seconds. Harold P. to take first shock every time till one of the duellists has had enough and publicly admits his error. He warns Westinghouse, however, that death has occurred in his experiments with alternate currents at 160 volts maintained for five seconds, and that men have been killed on the low-tension Jablochkoff alternating system.

New Metropolitan Central Station.—The first contract for a central station having gone to Westinghouse, considerable interest has been aroused as to who will receive the contract to carry out the second installation for the Metropolitan Electric Light Company. Detailed and finished specifications were prepared and sent out, and the tenders from English firms have been under consideration some time. We hear that the contract has been finally awarded to Messrs. Johnson and Phillips for the erection of a central station, the dynamos to be employed being the new alternating machines of Mr. Gisbert Kapp, who has lately made arrangements to join the firm as consulting electrical engineer.

Anglo-Belgian Telegraphs.—A decision of importance to persons telegraphing to the Continent has been arrived at by the Anglo-Belgian Telegraph Convention. The concession of the Submarine Telegraph Company has expired, and no further concession is to be granted to private persons. The two existing cables between Middelkerke and Ramsgate, and La Panne and Dover are to be taken over by the two countries, and, if necessary, three new cables, each with four conducting wires, are to be laid. The rate for ordinary telegrams is to be 2d., or 20 centimes, per word; and the returns are to be divided at the rate of 11·25 centimes for England, and 8·75 centimes for Belgium. The sums received for transit telegrams are to be divided equally.

Digitized by Google

American Progress.—While England is waking up a little in central station matters, it may be interesting to note one week's progress in the States, as chronicled in one column of the last number of the *Electrical World*: Barre, Vermont, 35 arcs; San Antonio, Texas, 1,000 incandescents; Jackson, Mich., 70 arcs; North Topeka, Kan., 50 arcs and 600 incandescents; Cincinnati, 1,500 arcs; Hoosac, 1,950 arcs; Indianopolis, 500 arcs; Annapolis, 200 arcs and 3,000 incandescents; Brooklyn, 200 more arcs; Charlotte, North Carolina, 2,000 incandescents; Bay Shore, 30 arcs; New York, new Edison plant, Thirty-ninth-street, two stations for 28 dynamos each begun running with two dynamos to start, rest to follow; besides others, numbers not given.

Extension of Telephony.—On the 9th inst. a special meeting of the Western Counties and South Wales Telephone Company was held at Bristol, to authorise the raising of additional capital consequent on the extraordinary extension of the company's system. Mr. Charles Nash, chairman of the directors, said that in order to meet the demand for telephonic communication over the company's system, the directors recommended the creation of 50,000 5 per cent. debentures, 30,000 being offered immediately. The telephone, he added, was gradually growing in favour, and in Portsmouth, Plymouth, Cardiff, Swansea, and Bath the company had several hundred subscribers. Before the end of the year the telephone would be opened between London, Birmingham, and Bristol.

The Engine-room Telegraph.—The Central News states that the Admiralty have definitely adopted into the service the engine-room telegraph and electric signalling system known as Willis' patent, which will replace the mechanical system now in use. The Willis' arrangement was subjected to the roughest practical test before its adoption, both on land and at sea, and was the only invention which met every requirement and successfully stood every condition of service. All new ships and vessels refitted will be supplied with these instruments. In appearance and in handling the new electric telegraph is much the same as the old mechanical system. Its greatest advantage is that signals can be acknowledged as understood, a point which greatly tends to reduction of accidents at sea.

Colbere's Microphone.—A new form of microphone with some points of interest has been devised by P. Colbere, of Berlin. In this a movable box on a support is almost filled with carbon disposed in the form of a receptacle and filled with mercury (or amalgam), which itself is covered with a layer of granulated carbon, on which rests the diaphragm. This diaphragm consists of a very thin plate of carbon, fixed by the edge between the two insulating rings. The plate is connected to one terminal, and the granulated carbon communicates with the other terminal of the battery. By reason of its extreme mobility, the mercury obeys the slightest oscillations of the diaphragm, and the transmission of sound by means of this microphone is said to be extremely good, and distinctly heard even at some distance.

St. James's Hall.—The installation at the St. James's Hall, which was supposed to be one of the finest installations on the Grosvenor circuit, has gone through sundry vicissitudes. Originally wired by Messrs. Thompson and Ritchie, it has passed under the hands of two or three other contractors for more or less tinkering—result, constant dissatisfaction. The management, seeing that this is a matter which concerns the public, have now given the work to be carried out, without specified contract, to the Acme Electric Works, under the direction of Mr. Arthur Cockburn, to rewire and thoroughly reorganise. Slate switches are to be fitted throughout, and Cockurn's patent fuses alone are to be used. The circuits are redistributed, and all the fuses for the hall are arranged on one slate base in the roof, where they can be easily replaced, instead of fuses to every group. New fittings are also to be fixed.

Electro-Harmonic Society.—The next smoking concert of this society will be held at the St. James' Hall Restaurant on Friday, January 25, when the following programme will be carried out: Part 1: Trio, "Wine! the Magician thou art" (Balfe), Mr. Arthur Thompson, Mr. R. E. Miles, and Mr. Alfred Moore; song, "I seek for thee in every flower" (Ganz), Mr. Edward Dalzell; new song, "Pour forth the Wine" (Hamish M'Cunn), Mr. Alfred Moore; solo flute, "Scotch Fantasia" (Sannelet), Mr. John Radcliff; song, "In a Distant Land" (Taubert), Mr. Arthur Thompson; song (by request), "The Raft" (Pinsuti), Mr. R. E. Miles; humorous song, Mr. J. Kift. Part 2: Part song, "Slumber, Dearest" (Mendelssohn); new song, "Fame, the Fiddler" (Molloy), Mr. Alfred Moore; song, "The Death of Nelson" (Braham), Mr. Edward Dalzell; solo flute, "Irish Fantasia" (Richardson), Mr. John Radcliff; song, "A Tar of the Queen's" (Watson), Mr. R. E. Miles; humorous song, Mr. J. Kift; finale, "The Watchman's Song" (Pearsall).

Endolithic Ivory.—In the making of switchboards, telegraph, telephone, and other electrical instruments, the lettering is a minor but important detail. The Endolithic Ivory Company, of 24, Well-street, Jewin-street, have sent us some specimens of their ivory lettering for these purposes to inspect and test, and the result is highly satisfactory. The specimens are beautifully white and polished, and the lettering very clean. On scraping the surface with a knife it took 50 scrapes to make the lettering even dull, showing that the lettering goes right into the ivory, and if each scratch means, say, several years ordinary wear, it can be seen that this process is far preferable to ordinary lettering where permanence is required. At the same time the price is far below that hitherto paid for engraving, even of an unsatisfactory kind. During the last year some hundreds of thousands of pieces for all purposes have been turned out, a large quantity being for address tablets, telephone and switchboard labels, etc. Single sets are supplied where necessary.

Elastic Foundations for Dynamos.—In many cases the vibrations produced by gas and steam engines in the buildings surrounding them are very objectionable, and M. G. Anthoni has been led to devise a method of overcoming this difficulty. The method is briefly as follows: A large trench is dug out, at the bottom of which is placed planking surmounted by a covering of sheet iron, on which is distributed a number of short vertical rubber cylinders, constituting at the same time an elastic and electric insulation. On the top of these cylinders there is placed a second plate of sheet iron, riveted to a framework, so as to give stiffness to the whole. On this is built a foundation in the usual way, provision being made for the foundation bolts, and sufficient space being left to properly allow of periodically cleaning the trough of any extraneous matter without disturbing the elastic supports. The steam and exhaust pipes are joined in the form of a large spiral at their upper ends so as to permit of their being elastic under the slight

Digitized by Google

movement which takes place, and thus avoid the springing of joints.

The Electric Traction Company at Barking.—We understand the installation at Green Gate, Barking-road, for working the accumulator cars on that section of the North Metropolitan Tramway is nearly complete. The engines are now being set up by Messrs. Davey, Paxman and Co., and the six new cars built by the North Metropolitan Tramways Company at their Leytonstone works are also being electrically equipped with the Immisch motors and E.P.S. cells, under the active superintendence of Mr. Thomas Fraser, the engineer of the Electric Traction Company. This company will undertake the entire working of the line in the course of the next few weeks. This will be the first commercial test in England of the value of accumulator cars as opposed to horses, and is being looked forward to with the keenest interest by the whole tramway world. The experimental car, of which we gave an exhaustive notice in September last, has been running most successfully for the greater part of the past year, and the Electric Traction Company are very confident that this demonstration will prove a commercial success, by doing the work equally efficiently and at a less cost than horses.

Ferranti Machines for Paris.—A considerable stir has been caused among electrical circles in France by reason of the judgment of the commission which was appointed to consider the tenders for the central station at the Halles Centrale, in which the contract for dynamos was awarded to M. Patin, representative of Ferranti. The council had resolved that all material should be exclusively obtained of French houses, and although the tender was sent by a French house the dynamos are of English construction, and the commission are confronted with the question that if one, then all contractors ought to be allowed the right to employ foreign manufacturers. MM. Mascart and Potier, the only two electricians appointed on the commission, report as follows. M. Mascart says: "If I had to choose for my own installation or for a central station to be erected by me, I should give preference to the Ferranti machines. But as representing the town of Paris, and judging on its account, I consider the advantages of the Ferranti machine over that of Zipernowski not sufficient to necessitate the council going to foreign rather than to French industry." M. Potier, in his report, comparing the three projects—Siemens, Zipernowski, and Ferranti—says the two last have the greater efficiency, owing to absence of iron in the armature. He prefers the three Ferranti machines to six Siemens machines, as being easier to manage. The tender for Ferranti machines is the higher by about 40,000f., but there is 12 per cent. greater output. With these there will be an additional 7,200 watts for each dynamo of 140 h.p.; or for two machines 14,400 watts at equal expense of fuel, salaries, etc. The price settled upon for supply to customers is 15 centimes per 100 watt hours. Taking only 10 centimes, and 1,000 hours a year supply, each watt will produce an increase of one franc in the receipts. If Ferranti machines are employed, this means an additional income of 14,000f., against which is to be put the interest on the additional 40,000f. It is true the project of M. Patin comprises dynamos of 113,000 watts, while the engines will only supply 90,000 at the outside; but the contractor has given written guarantee for an efficiency of 88 per cent. even with engines of only 140 h.p., and additional engine-power can be added. Under these conditions, if the financial guarantee given by M. Patin are sufficient, M. Potier advises the sub-commission to accept his tender for high tension machines and accessories.

Electricity in Mechanics.—The need there now exists for engineers in general to study and work with electricity is rapidly forcing itself on the attention of those who have hitherto been exclusively mechanical engineers, and instances are becoming common of well-known engineering firms setting apart an electrical department and engaging an electrical expert. An interesting article, inciting those whose special department is mechanical engineering to further study of electric science, appears in the *Stationary Engineer*. "Electricity," it says, "is steadily and surely working itself into many places where steam and water have heretofore been thought all-sufficient for the purpose, and it is daily showing its superiority in many places. It is less expensive, requiring less attention, occupying less space, can be placed directly at the work, and through the various contrivances designed for its utility it becomes a greater task to show wherein it cannot be used to advantage than to point out the method of its advantageous application. The engineer who fails to make a study of electric machinery will soon find himself supplanted by the man that has taken the trouble to learn the principles and study the details of dynamos and motors sufficient to be able to care for them as well as he does engine and boilers. The demand for electrical engineers is as great to-day as the demand for mechanical engineers, and in most places one man is required to furnish the ability of both mechanical and electrical engineer. This state of things is, of course, very unsatisfactory to some of us who are inclined to think that we are now furnishing enough work and knowledge for the pay we receive. This is all very true; but we must not for a single instant forget that the world moves, and if we do not keep our eyes and ears open and keep 'up with the procession,' we are certain to get left when there are any of the good things around. Yes, the world certainly does move, and the requirements of men in any position are greater to-day than they were a few years ago, and we engineers wrong ourselves if we think that we are any exception to the rule. We must master all the improvements that are encroaching upon us. We must make ourselves familiar with the natural laws by which they are governed, study their minutest details, and become so thoroughly familiar with them that we can understand their slightest action. This we find it is necessary to do, or we will be supplanted by someone who will. To keep up with the advances of the times, we find it necessary to learn. When we become thoroughly familiar with a machine we find that it is quite easy to care for it; if defective, investigate it thoroughly, study its action and learn if you are familiar with the principles upon which it is built and have given the necessary attention to details. The electric machines that are now finding places in the engine-room, and are necessarily in charge of the engineer, need not be feared because electricity cannot be seen, and its presence only known by the results. Neither need we be appalled by the fact that we do not know for certain what electricity is; that matters not, so long as we know the laws of its action and can control it to our liking. Mysterious as electricity may yet be, learn the few laws by which it is controlled and you are its master; disregard those laws and it turns upon you to injure or destroy."

THE INSTITUTION OF ELECTRICAL ENGINEERS.

The first ordinary general meeting of the old Society of Telegraph-Engineers and Electricians under its new title was held on the 10th inst., Mr. Edward Graves, president, being in the chair. It was announced that Prof. Silvanus Thompson had declined to receive the society's premium which had been awarded to him on the ground that he had been a member of council and that he considered such premiums were for other members than such as himself. The presentations of premiums were then made as follows:

The "Society's" Premium, value £10, awarded to Mr. Arthur C. Cockburn, F.C.S., member, for his paper on "Safety Fuses for Electric Light Circuits, and on the Behaviour of the various Metals usually Employed in their Construction."

The Paris Electrical Exhibition Premium, value £5, awarded to Mr. E. Stallibrass, member, for his paper on "Deep-Sea Sounding in Connection with Submarine Telegraphy."

The Fahie Premium, value £5, awarded to Mr. E. O. Walker, for his original communication "On Earth Currents in India."

The president-elect, Sir William Thomson, F.R.S., etc., took the chair and delivered his

INAUGURAL ADDRESS

On Ether, Electricity, and Ponderable Matter.

Gentlemen,—I beg to offer you my warmest thanks for the honour you have done me in electing me to be the first president of the Institution of Electrical Engineers. Fourteen years ago, when the then three-year old Society of Telegraph-Engineers honoured me by appointing me to be their president, the society numbered 570 members; it now numbers 1,550. It is gratifying to us to think how successful that young society, founded mainly, I think I may say, by Sir William Siemens, has been, and how much it has grown. But while we think with pleasure of the great increase of our members, that pleasure is saddened by the thought of how many of the old members are gone, and especially the first two presidents, Sir W. Siemens and Mr. Frank Scudamore. The genial presence of Sir W. Siemens is a happy recollection to many of us, I think I might almost say to nearly all present, and the thought that he will be no more with us is certainly a very great grief to all who have known him, a great loss to science, and a great loss to England. We look back upon Mr. Scudamore's presidency with great satisfaction, considering all that he did for the society, and his loss is deeply felt. Three of the presidents since I had the honour to serve are also gone, Mr. C. V. Walker, Colonel Bateman Champain, and within the past year Sir Charles Bright. The first Atlantic cable of 1857 gave me the happiness and privilege of my first acquaintance with Sir W. Siemens, and in the course of that work Sir Charles Bright was my colleague. He was engineer to the company, and I made his acquaintance during the 33 days when we were out of sight of land in the ever memorable "Agamemnon" expedition of 1858. Sir Charles Bright was there full of vigour and enthusiasm, and to his vigour, earnestness, and enthusiasm, in a great measure, was due the existence of the temporarily successful cable of 1858, and of the great consequences which followed from it, even though that cable itself had a very short life, having only three months of working time, and not more than three weeks of really practical useful work. Still, we must always look upon Sir C. Bright as a pioneer in the great work when other engineers would not look at it, and who thought it was absolutely impracticable; we must always look back upon our late colleague, lost within the last year, as having done great things indeed for the subject of the Society of Telegraph Engineers. The Society of Telegraph Engineers has grown, not only in membership, but in the extent of its province from the time of its foundation until now. It became the Society of Telegraph Engineers and Electricians a few years ago, and now the more appropriately representative title of the Institution of Electrical Engineers has been adopted. The original name included only telegraphy, but that was not then the only application of electricity to engineering—there then was electrometallurgy. Telegraphy and electrometallurgy were, I think, the only two branches of practical science to which electricity had then been applied, but since that time we have had a vast augmentation of the field. We now have telephony—electric transmission of power. The society may well recollect Sir W. Siemen's inauguration of the great subject of the electric transmission of power on a scale of practical usefulness. I think we may safely feel that to the Society of Telegraph Engineers in a large measure is due that practical development of electricity. We have now power electrically transmitted through factories to drive separate machines by separate motor-dynamos; we have now electric haulage, electric tramcars, and many other fields; we have the application of electricity to naval and military purposes, and, last but not least, we have the application of electricity to electric lighting. With all these grand subjects of applied practical science for our province, I think the Institution of Electrical Engineers may feel that it has a great and noble dominion. I find it difficult to remember the new title, but I am proud of it, as I am proud of being its president, and I would mention our allied society, the Institution of Civil Engineers, and remark that the province of the electrical engineer necessarily touches upon that of the civil engineer. When, 14 years ago, I gave my inaugural address, I endeavoured to impress upon the engineering world that architects made a great mistake in not being engineers, and in not qualifying themselves as engineers, and doing the work of engineers; that architects did not do their duty to their clients in not being engineers and understanding the engineering of the works, and making engineering science, particularly the dynamics of engineering, an essential part of the training of an architect. It is not necessary to make any animadversion on electrical engineers. I think in this respect electrical engineers know well that they must, before all, be engineers: they must be engineers, and they must learn engineering. Young persons who have a taste for electrical machines—and who that is young has not a taste for electrical machines, sparks, flashes, the artificial aurora borealis, and phosphorescent effects with the influence machine?—think they would like to be electrical engineers, and they think that electrical engineering is all ether and electricity. Now, I have continually to impress upon many anxious mothers, parents, that their sons must condescend to learn something of gross, ponderable matter, that electrical engineering is not all electricity and ether, but that the mechanics of ponderable matter is also part of the subject. The youthful aspirant to the honourable profession of electrical engineering ought to learn mathematics and dynamics. After having the elements of a good general education, he ought to learn mathematics and dynamics well; then a good deal of chemistry and regular mechanical and civil engineering, besides electricity. It may be said that juvenile life is too short. I do not think it is. I think if the other subjects are well learned, electricity may be learned in a few months. I am perfectly sure that, if a youth is qualified in other departments, the mere admission of electricity to the education of a competent engineer will not take so very long a time, and that the merely educational part of the work will not be protracted unduly by adding electricity to the branches learned in general engineering. I do not mean to say that if electrical engineering is the branch adopted there is not a prodigious and endless field proper in which the worker will learn every day of his life, though he lives more years than any person present. I wish just to make these few remarks in the beginning because they do seem to me of some practical importance, and worthy therefore of being put in the front of the remarks that I have to offer as the first president of the Institution of Electrical Engineers. And now these remarks have suggested to me a subject for the scientific exposition that I might give you in this evening's address—that is, Ether, Electricity, and Ponderable matter. The demand for something like a mechanical explanation of electrical phenomena is not new, but it is growing in intensity every year. The proceedings of recent meetings of the British Association, and especially of the last meeting of the British Association, illustrate the growing desire to know something below the surface, to know something of the inter-

Digitized by Google

nal relations connected with these wonderful manifestations of force and energy which are put before us in the action of a magnet and in the working of an electrical machine. The addresses of past-presidents of the parent Societies of Telegraph Engineers and Telegraph Engineers and Electricians illustrate also the growing desire to know something of the molecular theory or dynamical theory of electricity and magnetism. Mr. Preece, in his address, pointed out how Maxwell had shown the velocity of light to be related to electricity in such a way that we can scarcely doubt but that the propagation of electromagnetic disturbances through space (which we have every reason to believe does exist, which, in fact, from known laws, we may say certainly does exist) we may believe it to be propagated with a velocity equal to that of light—that the propagation of electrical disturbance and of light may perhaps be identical. Mr. Preece alluded to the disturbance of the sun's surface, and simultaneous magnetic disturbances which had been observed in his telegraphs, and other operations of an electromagnetic character on the surface of the earth. Many presidential addresses, I rather think, though I may be wrong perhaps in my recollections, have opened the ground of the keen desire of an electromagnetic theory. Mr. Preece's address was in 1880; in 1883, if I remember right, Mr. Willoughby Smith alluded to some experiments which I considered to be very beautiful and instructive, which he was making, and of which he only gave a very slight reference in his address, illustrating the screening effects of sheets of different kinds of metal upon electromagnetic and electrostatic inductions. Electric inductions simply, we may say, because we began to fail to distinguish between electrostatic inductions and electromagnetic inductions. In his subsequent work Mr. Willoughby Smith gave an exceedingly beautiful and interesting illustration of the screening effects of lead, copper, and iron, of which a slight sketch was given in his presidential address. About the same time the subject was mathematically worked out with great power by several mathematicians, but perhaps most notably by Horace Lamb. I feel it almost invidious to mention names; there are so many workers who touched upon the same subject. Charles Nevin,* almost simultaneously with Lamb,† went through very much the same kind of work; in fact, obtained the same solutions of some important and interesting problems regarding electric currents in spherical conductors. There may be some difference with these two writers in point of priority, but I mention Lamb's name because the screening is more particularly developed in his great mathematical paper. In that ever memorable presidential address of Prof. Hughes another allied branch of electromagnetic induction was very admirably illustrated by experiments which are now more or less familiar to us all, but which are of themselves of an immensely suggestive and stimulating character both to mathematicians and to experimental workers. The very criticisms by mathematicians upon some of the experiments and modes of statement by Prof. Hughes have, with Prof. Hughes' own statements, given a stimulus and suggested mathematical and experimental scrutiny that might have been wanting for many a year.

One of the earliest problems in which electrical induction had to be considered was that of submarine telegraphy. The subject of induction in telegraph wires presented itself in a peculiarly perplexing way to the first workers in that department. There was the general knowledge of electromagnetic induction between two wires, which had been worked out by Henry and Faraday in a very full manner; that was the only kind of induction that was thought of by some of the pioneers of submarine telegraphy. Another kind of induction more thought of by others was the electrostatic induction due to the Leyden jar charge of the insulated wire. Faraday, in this department, as in the other department, was the origin of nearly all that we now know. Faraday explained in a very beautiful and clear way the electrostatic charge of the submarine cable, and showed how the electricity conducted through the cable from one end, to give what of potential is necessary in the middle or the other end of the cable—in the middle of the cable for any mode of working, at the other end of the cable for modes of working in which the other end is insulated—gave rise to the Leyden jar charge. Faraday pointed out (without going into any of these details, however) the doctrine of the conduction of electricity through the wire to supply the Leyden jar charge, which the wire must have, in the course of working, in order to be raised to the difference of potential from the earth required to cause the signal current to pass through it. Cromwell Varley made very important advances in that direction. At the meeting of the British Association, in 1854, in Liverpool he brought forward some very important developments of Faraday's doctrine. Then came on the great Atlantic cable question, and I always remember how that question came upon me. I see in Prof. Stokes 'presence with us this evening a reminder of the circumstances. I was hurriedly leaving the meeting of the British Association when the son of Sir William Hamilton, of Dublin, was introduced with an electrical question. I was obliged to run away to get a steamer by which I was bound to leave for Glasgow, and I introduced him to Prof. Stokes, who took up the subject with a power which is inevitable when a scientific question is submitted to him. He wrote me and some correspondence passed between us, and the result was that a little mathematical theory was worked out, which constituted, in fact, the basis of the theory of working submarine cables. In that theory electromagnetic induction was not taken into account at all. Leaving it out of account was justified by the speed of signalling which the circumstances of a cable extending 200 or 300 miles in length dictated. For a cable of more than 200 or 300 miles the speed of working was essentially limited by these electrostatic considerations, limited so much that the electromagnetic induction certainly could have no sensible effect; but the possible speed of working in a cable of 20 miles, 50 miles, or even 100 miles, was so great that in short lengths like those the electromagnetic induction might come into play. I worked out the subject partially myself. I found it necessary to do so to satisfy myself that the doctrine upon which the Atlantic cable project, then growing up, and upon which it was ultimately founded, was thoroughly trustworthy. I found it necessary to investigate the question of electromagnetic induction. This question was further forced upon one by communications that I had with my friends, Lewis Gordon and the two brothers C. W. Siemens and Werner Siemens, with reference to the Mediterranean cables. It was imagined that electromagnetic induction alone was the obstacle, and that the embarrassment in working through a submarine cable was due to electromagnetic induction alone. On going into the subject fully, it became demonstrated that electromagnetic induction would have no sensible effect in the proposed Mediterranean cables, and thus the proposal to put two thin wires close together in order to obviate electromagnetic induction was given up. Experiments in Germany had shown considerable electromagnetic induction on short lengths of cable, and that that embarrassment, or whatever it may be called, was diminished by using wires very close together. It was shown that the diminution of electromagnetic inductive influence would produce a corresponding increase in the electrostatic inductive influence, and when it was pointed out that the electromagnetic inductive influence would be absolutely insensible at the highest speed of working the proposed cables, the idea of making them of twin wires, close together, for metallic circuits was given up and the present type of cable was adopted. But now it is very interesting to us to find that old question revived. I myself laid it aside; it was in a corner of my mind, and in some corners of my notebooks, for some few years, and within the last forty days I have actually worked it out to the uttermost—really, for my own satisfaction. But in the meantime it has been worked out in a very admirable and complete manner by Mr. Oliver Heaviside, and he has pointed out and accentuated the result of his mathematical theory that electro-

magnetic induction is a positive benefit. It helps the current, it is the same kind of benefit that mass is to a body shoved along against a viscous resistance. Suppose, for example, we had a railway carriage being moved where there had been an inundation, through a quantity of mud or other matter which obstructed its progress. Or take a boat on wheels. We cannot take a boat in a fluid on account of the gravity, but suppose two boats of the same shape in a viscous fluid, one of them being ten times the mass of the other. If they are shoved off with a certain velocity, the boat of greater mass will take greater force to give it its impulse, but it will go further. That is Mr. Oliver Heaviside's doctrine of electromagnetic induction—it requires more electric force to produce a certain amount of current, but the current goes further. My example is a very crude way of putting it, and does not do justice to Mr. Heaviside; but the whole thing is worked out in a most complete, simple way, and the fact that the effect of electromagnetic and electrostatic induction taken together—they cannot be separated—is fully worked out. One thing that was known of old is made the subject of Mr. Heaviside's treatment of the cable proper--that is, the beneficial effect of leakage in clearness of signals. All telegraphists remember that, and two or three leaks in a cable, if they would remain constant and not introduce the extra trouble of earth currents, make the signals come out more distinctly; that used to be known, and the general reason was pretty well known and pointed out by mathematicians. Now Mr. Oliver Heaviside has taken that subject, and included it in his work. He has included induction of this kind along with electromagnetic induction; he has particularly accentuated it, and it is a practical point of importance that the question of clearness of signals is not simply, or even very important, how much is the current alternated at the remote end of the cable, how much is the amplitude of the electric current (or of the variation of the electric potential in another mode of working), attenuated in transmission through a thousand miles or two thousand miles of cable. A certain range is given at the sending end; what is the range at the receiving end? That is an important question, but it is not the most important question with reference to the clearness of signalling—in fact, we might almost say it is not an important question at all, because there are certain restrictions and limitations as to the speed with which submarine cables can be worked in respect of high potential. Setting that idea aside on the one hand, and considering the practical sensibility of the instruments on the other side, we have a large margin, even in submarine cables, for increasing the working power on the one hand, and increasing the sensibility of the instruments on the other. It is not the smallness of the signals at the receiving end that is the real difficulty in a submarine cable just now at all—it is the running of one signal into another, it is the want of correspondingly definite features between a single signal or a group of two or three signals at the receiving end. There are two things to be considered in respect to the distortion, as Mr. Heaviside has called it, of the signals in passing through a cable—one thing is the retardation of phase, another is the diminution of amplitude. If the retardation of phase was the same for periodic currents, alternating currents of all periods, then the retardation phase would be of no consequence whatever — it would not impede the distinctness at all. Again, if the diminution of amplitude was precisely in the same proportion for alternating currents of all periods, then, when we came to make up the signals, we should find that the signals would be transmitted with perfect sharpness. In fact, if we compare the transmission of electric signals through a wire with the transmission of sound through air, we have in the case of transmission of sound through air great alternation by distance, inversely as the square of the distance in fact, but the same for all notes. Again, retardation of phase depends upon the velocity of sound, the same for all notes; the result is that speaking, musical performances, and signals of all kinds in air lose none of their clearness by distance. It is just a question whether the very greatest distance at which a sound can be heard is due to any want of clearness, due to different alternations of the different notes, or the different elements forming the compound sound, or difference of retardation of phase. I must not keep you too long on this subject, but it is one of much practical importance. Mr. Oliver Heaviside considers that electromagnetic induction causes a less great difference in the attenuation of different periods than there is without it, and that electromagnetic induction, as we knew 40 years ago, tends to reduce the retardation phase to the same for all different notes, and, in short, the phase of electric signals is retarded exactly as much as the phase of luminous vapours is retarded if the signals have but sufficient frequency for the circumstances. It was known to the earliest workers in the subject, and Kirchoff pointed out that it was approximate to the velocity of light; and Maxwell arrived at a probable explanation of electrical effects by the influence of a medium, showing that the medium must be ether—the medium to whose motion light is due. Maxwell's electromagnetic theory of light marks a stage of enormous importance in the electromagnetic doctrine, and I cannot doubt that in electromagnetic practice we shall derive great benefit from the comparison of electrical effects, line by line following Heaviside's theory of dealing with submarine cables, and showing how greater clearness is obtained as that condition is approached. The comparison with light and sound is just one instance of how the highest mathematical power of working and judgment as to physical applications helps on the deep and profound theory, and drags it into a practical channel. The telephone, one of the added subjects of the society of which we are members, illustrates very splendidly these developments of the theory of the transmission of signals through a submarine cable. The telephonic signals have, in fact, sufficient frequency to make electromagnetic induction very sensibly influential, the frequencies corresponding from 250 periods per second up to two, three, or four times that which are the frequencies involved in speaking. The human voice, tenor and soprano, and the quality of the voice as affected by the overtones, also periods of frequencies of from 256 periods per second to 1,000, or 1,500 frequencies per second, are concerned in the fundamental notes and in the characterising overtones of the sounds transmitted by the telephone. There seems, no doubt, that the clearness of the telephone is, to a large degree, due to the circumstances that Mr. Heaviside has pointed out, that we have much less difference of attenuation for different notes, and that the frequencies of the notes in a telephone were independent of the practical dimension of the telephone wire. I can scarcely speak on this subject without just touching upon a question which I do not propose to enter fully upon to-night, that is the efficacy of iron and copper as telephonic conductors. The information given to me by Mr. Bennett, the engineer of the National Telephone Company in Scotland, leaves no doubt whatever but that there is very considerably less of clearness in speaking through an iron wire, such, for instance, as the first metallic circuit iron wire of the Post Office between Glasgow and Edinburgh, than there is in speaking through a copper wire of the same resistance. I shall say no more of this just now; it is an exceedingly difficult and complicated subject, but with Mr. Heaviside's investigation and with Lord Rayleigh's special investigations on the susceptibility of iron to very small differences of magnetic forces, differences of magnetic forces superimposed on even powerful magnetic forces or a large residual magnetism, the matter is in a very hopeful condition. The subject is in good hands, mathematical and practical, and I think before many months pass of the existence of the Institution of Electrical Engineers we may have an absolutely clear understanding of telephony through iron wires compared with telephony through copper wires. I intended to put a few figures on the board, but unfortunately they were left in a hansom cab, and I can only quote from memory. I made calculations for the problem of alternate currents through copper wire. I have not applied it to iron wire yet, but for either telephone wire or electric light wire with alternate currents I worked it out in Bessel's functions—every mathematician knows how to do it. It is an extension of Bessel's functions, a problem of periodic variations at one end of an infinitely long copper wire, or difference of potential between two parallel copper wires o a copper wire and a copper tube surrounding it

Digitized by Google

for return—we may vary the thing about very much, according to circumstances. But after all, one of the very simplest things is this, two parallel copper wires. If the distance between them is a large multiple of the diameter of each, as is the case in practical telegraphy and telephony, the problem is as easy as the problem of a single copper wire in the centre of a cylindrical tube of copper. Well, now, as Mr. Heaviside remarked, and as everyone who has worked out the subject must have known, the distribution of currents within a copper conductor is quite independent of the surroundings, provided only they be symmetrical all round, or provided they be that of two parallel wires where the distance between the two wires is a large multiple of the diameter of each, and where the current in each is not sensibly influenced by that in the other by being arranged in concentric cylindrical areas of equal current density. Well, now, the distribution depends simply on the frequency, not at all on the surrounding circumstances. While speaking on such an abstruse subject as electricity, ether, and ponderable matter, I wish just to give one little piece of practical information to some, though it may not be to all. The table I have prepared will, I hope, appear complete in the report of this address, but in the meantime I will try and give one or two of the numbers which are rather interesting. Take 80 periods per second as the frequency, that is about what is conducted in the alternate-current system of distribution; at all events in one light system I know of—in the Grosvenor Gallery installation—that is the period of frequency, and I believe it is very much the same generally. Let us take this as an example. Eighty periods per second, take copper wire of one centimetre diameter, two centimetres diameter, and so on. Well, now, in copper wire of two centimetres diameter, the ohmic resistance is 8 per cent. more for the alternating current than for the steady current; in copper wire of 4 centimetres diameter the ohmic resistance is 63 per cent. more than for steady currents; in copper wire of 10 centimetres diameter the ohmic resistance is four times that it would be for steady currents. This is an interesting result—in copper wire of 100 centimetres diameter the ohmic resistance is 17 times as great as it would be for steady currents. It is also interesting that from 10 centimetres diameter upwards the ohmic conductance—that is, the reciprocal of the ohmic resistance—increases sensibly as the circumference simply, and not as the square of the diameter. The conductance for steady currents is as the square of the diameter all through; the conductance follows a law only expressible by these developments of Bessel's functions until we get to a certain diameter. When we get to so great a diameter that the shell, so to speak, the outer portion of the wire into which the current is practically defined, is moderate or small in proportion to the diameter of the wire, then above that you can all see without calculation that the conductance is in simple proportion to its circumference. You may say, practically, that from 10 centimetres upwards the ohmic resistance is in simple proportion to the circumference, with a deduction in the ratio of 79 to 70, the figure 79 corresponding to 10 centimetres diameter, 70 corresponding to an infinite diameter. This very imperfect explanation of the results may give some idea, but the complete table will show them for all sizes of copper wire from nothing to infinity. With a quadruple frequency the same figures apply to half diameter; there we get the telephone problem $80 \times 4 = 320$, that is among the frequencies for telephonic notes. Take the figures I have given, for instance, copper wire of 1 centimetre diameter for musical notes of 320 periods per second, the ohmic resistance is 8 per cent. greater than the resistance for steady currents; for a copper wire two centimetres diameter, frequency of musical note 320 per second, the ohmic resistance is 63 per cent. greater than the resistance for steady currents, and so on. Another important development from this theory is that there is much less importance in the conductivity of the metal for a telephonic wire than for ordinary electric work when we try to attain to it by thick conductors, such as I have been indicating. For example, take copper wire of 2 centimetres, the figures are a little complicated, but I will only say that, when circumstances are properly proportional, it is the square root of the resistance that we have to deal with instead of the simple resistance. Speaking roughly, the quadruple resistance is only twice as bad when the frequency is so great as to cause the effect of the ohmic resistance to be very much greater than the resistance for steady currents. The moral of this is not that you may choose wire of bad conductivity; on the contrary, take the best conductivity you can get, whether for telephones or for electric light conductors, but shape them so that the ohmic resistance shall not be too much augmented by the change of distribution of the current from uniformity which electromagnetic induction entails. The principles of working these are pretty well known to practical men, so that I do not think I need say much on the subject now. They have been known for a long time, but we are not much "forrader" in respect to the great question of electromagnetic theory. We have had a fine analogy from the time the known laws of electromagnetic induction were put into formulæ in the beautiful manner in which Maxwell put them, with the motion of a viscous fluid, the equations for which were given originally by Prof. Stokes. These considerations regarding the distribution of electric current in a conductor such as copper, and the distribution of motion of water in a viscous fluid disturbed by periodic variations at the surface, follow identically the same law. Mr. Heaviside, referring to this, has well said that this analogy is very useful because we can see the motions in a viscous fluid, and understand them and picture them to our minds, for it is more difficult to fancy we see the distribution of an electric current in a wire. Take this analogy. I am speaking of the distribution of electric current in a round copper wire, through which alternating currents of electricity are sent. Take a viscous fluid in a tube in place of the conducting wire, move the tube to and fro with a regular alternating motion, a simple harmonic motion. Imagine the tube I have here to be one of very great length filled with viscous fluid, such as treacle or thick oil, and having pistons at its ends to fulfil the laws that I am speaking of; the length must be very great in comparison with the diameter, and the place where we look at and think of the fluid is very many diameters from the ends disturbed by the pistons. In the first place, in such a tube, fitted with frictionless pistons, if the fluid were non-viscous, if it were perfectly liquid, the tube might be moved, but the fluid would not move at all. Water would move, but the more thick the fluid the more liable is it to take motion in that way. There is a perfect analogy between the motion of the fluid, the alternating motion of the fluid, transmitted inwards from the surface, and the distribution of electric current in a wire through which the effect of an alternate-current machine is being conveyed. Another very interesting analogy, which has exactly the same law as the other, is change of temperature in a conducting solid due to variations of external temperature. We have got our tube of fluid; imagine there a column of rock or stone, or metal, and instead of moving the tube to and fro longitudinally, let the atmosphere and surroundings of the stone column, or iron column, or metal column, be periodically varied in temperature. The law of penetration, of maximums, minimums, and zeros midway between the maximum and minimum of temperature in the one case is identical with the corresponding law for electric current in the first-mentioned case, and of fluid motion in the other cases. In each case we have a propagation inwards with diminishing amplitude; in each case the rate of diminution of amplitude corresponds to the retardation of phase according to exactly the same law. I need not take up your time in giving the law, but you can easily understand it. Well, now, we have a very perfect electromagnetic analogy for the simple case in the to and fro motion of a tube. Take another case. Here the thermal analogy fails us, it absolutely fails us; it is absolutely inapplicable to what I am going to speak of now. The fluid motion analogy still holds; take a tube of fluid and give it a motion round its axis; that action will give a tangential drag if the motion be very quick, and will follow the same law for the to and fro motion of the cylinder, and for the rotary motion of the cylinder. The question is this: Does the variation penetrate to a large distance in from the outside or not? If it penetrates in to only one-hundredth of the radius, then it is obvious that

Digitized by Google

we shall have the same law of penetration inwards for the disturbance, whether for the case of rotatory motion of the cylinder round its axis, or of longitudinal to and fro motion; exactly the same thing holds with electromagnetic induction. The one case that I mentioned first is the most important for telegraph and telephonic current, but another of equal importance is that of a core within a solenoid through which an alternating current is being sent in opposite directions, producing magnetic lines of force parallel to the axis of the interior of the solenoid. Alternating magnetic forces induce electric currents in circles perpendicular to the direction of the forces; thus we have, as you all now know, currents induced in the solid metal core of a solenoid. A metallic core, such as iron, is a subject for investigation of an exceedingly easy character. The same Bessel's functions come in here just as they do in the other cases. But the inductive quality of iron, the different degrees of magnetisation according to circumstances, the increase and diminution of magnetisation or reversal of magnetisation, the great complications of inductive effects experienced with iron, introduce corresponding complications in the theory of the induced current, and other complications of a kind that present most formidable difficulties for mathematical analysis. The mathematical citadel of truth is there impregnable by any mathematical power that has yet been brought to attack that variation of magnetic susceptibility when the strength of the magnetic induction or magnetising force is taken into account. I am only going to say two or three words about an extension of that viscous fluid theory that allows us to take into account all that goes on both in air and in metal. I will confine myself to two very simple cases—parallel wires with alternate currents through them of the rotatory case; one cylinder rotated with a periodic motion of rotation alternately in opposite directions. The analogy I will state very shortly; it is simply this—to represent different metals in the analogy, densities of fluid proportional to the electric conductivity must be taken; the viscosity must be the same in all. The representative of an insulator in this analogy is a massless fluid almost devoid of inertia; perhaps I ought to say an inertialess fluid, because people attach their ideas to mass sometimes rather than to inertia, but in strictest dynamic language mass is taken as inertia. The inertialess viscous fluid must take the place of air; a viscous fluid of a certain density, but the same degree of viscosity must take the place of lead. Then, again, to take the place of copper, a fluid of six times the density of lead —the conductivity of copper being, say, six times the conductivity of lead—a fluid of six times the density is the analogue of copper in the viscous analogy. I shall not pursue the subject further, because to work it out with illustrations would run into more time than can well be afforded on such an occasion as this; but I would just call attention to the other case of rotation—exactly the same statements hold. I shall return to that presently, because I am going to speak of iron. When we come to iron, there is no difficulty whatever in considering the one or the other; but now one thing is hopeless—that is hardly the word: we are never without hope in science. I was going to use another word—despair. I feel the probability of my seeing the solution of it, I may say, is hopeless— the electrostatic effect. To get the analogy of electrostatic effect simply put in an inter-phase between the two surfaces, and give it such stiffness against change of shape as to require it to fulfil the conditions which our knowledge of the laws of electromagnetic influence teaches us exist. Put in at the inter-phase the requisite normal force, and the solution can be extended to include the submarine telegraph problem—that is, with electrostatic charge taken into account; the complete problem of a submarine cable where electromagnetic and electrostatic induction are both taken into account—but it is only by putting in quite an arbitrary manner a force at the surface to fulfil the requisite conditions that we can complete the analogy. The analogy I have just sketched cannot be considered as being in any respect a physical analogy. It is not molecular rotation of the fluid, the analogue to electric current is not velocity of the fluid—it is a quality derived from the simple motion of the fluid by the operation known as the Laplacean operation. The Laplacean of u, v, w is the electric current. Another way of putting it is the rotation of the rotation of u, v, w. The word "curl" was introduced by Clifford and Maxwell, and has, I grieve to see, been adopted by Mr. Oliver Heaviside. I object to the word—curve is good, but curl is bad, and the method seems to be not desirable or instructive, and, above all, not applicable to any practice of mathematics. It is too difficult a subject to explain now, but I will, just by an illustration, try to illustrate it by a case. Take in the viscous fluid analogue what corresponds to the steady current in a wire—here it is. Think of a tube, at one end of the tube press a piston in with a uniform motion in the neighbourhood of the piston. The motion is disturbed by the rigidity of the piston, and to a distance of 10 or 20 millimetres from the position the motion of the fluid takes a perfectly regular character. Suppose (diagram drawn) that represents the inner surface of the tube; a portion of the fluid is sticking to the surface —there is absolutely no slip at the containing surface. I make it to exactly represent a parabola, with its vertex in the axis of the tube. The surface is that of a paraboloid of revolution. The effect of the drag is a maximum at the side of the tube and zero at the vertex. We have two functions derivable from the consideration of the depreciation of the velocity. The first is the rate of shearing of the fluid, the second is the rate of change per unit change of distance from the axis of the rate of shearing. First, then, the rate of shearing, then the rate of change of the rate of shearing. The rate of shearing is equal to the tangent of the inclination, the angle i, the tangent of the angle of this curve to the transverse surface. The rate of change of the rate of shearing from point to point is the analogue of viscous fluid force through a tube. In it we have not the average velocity equal to velocity of electric current, but something quite intelligible and very clear, but it is not the velocity of the fluid. Now, perhaps, there is this in this idea—I think we have a mathematical definition of electric current which is not fluid velocity. Well, now, perhaps, some will say, Had not we better get an analogy in which fluid velocity is equal to the velocity of electricity? I do not say whether we had better or not, but this analogy gives us a motion of which the rotation is the magnetic force. Mr. Heaviside rather overlooks that merit in Maxwell's vector-potential; he objects to Maxwell's vector-potential. I do not like it, and heartily agree with him because I think it is an unhappily chosen name. Maxwell puts down in his formulas (as the foundation from which one step leads to magnetic forces, and the next to electric current) something which, when translated, gives us a mean of which the rotation is the magnetic force, and it seems to me that if we are ever to have a real theory here, it must be founded upon this view. The hand of the clock warns me that time is going on so rapidly that I must leave this analogy absolutely unfinished. Perhaps it is as well that we are obliged to leave it now, because the more we look at the result the less we like it if we wish to see a true mechanical explanation of electromagnetism. It is only a dream, an idea of a possibility that may ultimately lead to an explanation of magnetism. The work, the energy, is done in the wrong place. We find work done in the dielectric, this viscous, this massless fluid taking the place of the fluid. I must now leave it, but the reason that so much notice has been given to it to-night is that it is a perfect mathematical working analogy, and will be a useful and instructive kind of analogy, and a very potent aider in getting out and estimating out practical problems in respect to magneto-electric induction in dynamos, telephones, helices of electrical instruments, wire, and so on, in great variety of shape. But now there is another thought in connection with this subject, and that is the elastic solid thought. Will you allow me to read a very short statement which was published in the *Cambridge and Mathematical Journal* for the year 1847. It is dated Glasgow University, November 28, 1846, and it was written after I had been 28 days in my professorship, and is as follows: "Mr. Faraday, in his 'Experimental Researches in Electricity,' has set forth a theory of electrical induction which suggests the idea that there may be a problem in the theory of elastic solids corresponding to every problem connected with the depreciation of electricity, or with the forces of attraction and repulsion exer-

cised by electrified bodies. . . . . I should exceed my present limits were I to enter into an examination of the state of a solid body representing the various problems of electricity and galvanism, which must therefore be reserved for a future paper." I can say that now as I said 42 years ago. I have been considering the subject for 42 years night and day—I do not mean all of every night and all of every day—but there have been but very few days and nights on which I have not tried to find it out, but have not found it out yet. But we feel almost as if we are approaching towards it when we think of viscous fluid forced through a porous portion—a tubular portion filled with porous elastic matter. Let there be an elastic solid of exceedingly small density, and let there be a portion of it porous, but with the same aggregate rigidity, taking rigidity now instead of viscosity, somehow or other force a fluid through it; the pull of that fluid upon the porous solid will produce identically the same static rotations as we have of dynamic rotations, continued rotatory motion in the case of the viscous fluid—in fact, nothing but electricity and ether. The thing would be done. I would be perfectly satisfied if I were in the position of the juvenile electrician who thinks it is all electricity and ether, as if there was not another body—grave, ponderable matter. I should be perfectly satisfied if it could be so, but I cannot deal with that now. As to magnetism, I said I would return to that, and I want just to call your attention to this. Imagine (diagram drawn) to be the section of an ordinary helix or solenoid representing the copper core, through which an alternating current is passing. Whatever the current of electricity may be, I believe it does pull the other round. I do not think this is a dream of electromagnetic theory; I believe it to be reliable. Astronomers do not cry out and make their lives miserable because they cannot explain the motion of the earth through this elastic solid ether. It is an absolute mystery, and people who deal with optics and astronomy are not expected to be miserable because they have that difficulty and mystery ever before them. Are we to be absolutely unhappy, then, because while we say it moves, we cannot by any possibility say how it does move; no greater mystery with reference to the laws of matter has ever been suggested or imagined. Somehow or other, however, the ether is pulled round, it has got a twisting motion like that in the interior of a solenoid. Somehow or other it does give motion to the copper, and somehow or other there is a motion following these very laws that we have been speaking of, and illustrating the viscous fluid analogy somehow or other in the copper. Now, instead of an alternating current through the helix, take a constant current. A constant current; what can it do but turn round the ether to a constant angle? Just one other thing is possible: it might keep dragging the ether round and round; either one thing or the other it does. Either a constant current through this helix does drag the ether round and round inside it, or it drags it round to a certain angle proportional to the strength of the electric current; it does either the one or the other of these two things. Now, how on earth can iron differ from copper? Our interphasial law, depending on equal viscosities, is very simple; but when you introduce iron, you introduce an interphasial difference without anything that could possibly be a cause of viscous action whatever, or a cause of electrostatic action. A cause of electrostatic action requires distortion: you have no elasticity of an elastic solid without distortion. Well, now, all that you can do by applying a tangential force all round a cylinder is to turn it; if you keep turning the circumference you will keep turning the contents; and if you turn the circumference to a certain angle and leave it you will turn the contents to the same angle and leave it, and all the contents must be turned to the same angle. That is all we can get either from our viscous fluid analogy or the other analogies. The primary phenomena of the magnetisation in a bar of iron, the core of a helix, absolutely leaves it behind, and cuts the ground from under us in our viscous fluid analogy and in our elastic solid analogy. If it is to be a fluid going round and round, we must have an action depending upon the fact that all goes round together; if we have no action round and round, but merely a certain drag of the ether round to a certain angle, and then turning to equilibrium, we must have a force resisting steady rotation—we must, at first sight, have this debatable property of matter. Here is a solid body, I apply a force to it, a definite torque—that is, the effect of a couple of forces tending to twist (it is now called a torque, and not a couple)—a certain torque tending to twist a body round carries it round and round with accelerated motion. Well, now we must have an arrangement of matter in which a constant torque produces a constant angular displacement in a body, and does not produce rotation. The only thing that can do that is an inherent rotation existing in the molecules of matter. That seems the only thing that can do it, and that can do it certainly, unless you introduce this other idea that an elastic solid may be moored in space, but even that must be movable ether. The gyrostat shows the thing, and I will conclude with a perfectly well-known experiment with the gyrostat that will illustrate application of it with reference to the idea of a medium which has the properties of an imperceptible fluid, and no rigidity except what is given to it gyrostatically. Here is a representation of a molecular skeleton that can give us such a fluid, consisting of a set of squares joined by flexible threads. Here

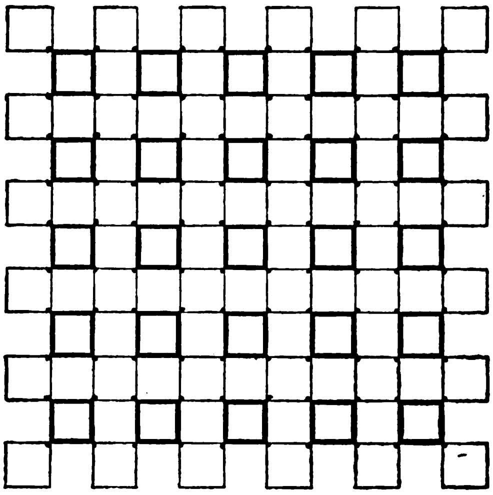

FIG. 1.

is a square pattern of rigid squares; the corners are connected by endless threads. There are 16 squares, and I have nine rigid endless wire squares connected with corners in this pattern. If these be pulled out with equal force in all directions, we have a kind of web. Well, now, in an ordinary cloth we can pull it in all directions in the direction of the warp and in the direction of the woof, and you cannot stretch it; but pull a thing like a pocket-handkerchief at 45deg. to warp and woof, then you can stretch it. You all understand that; surgeons do that generally, I think, for their bandages. Suppose the cloth is unstretchable except in the diagonal direction; the same with these squares: if you alter a square into a rectangle the area remains sensibly unchanged. The first change of the area is a diminution in whatever direction you do it, but that is proportional to the square of the strain, so that you may say, mathematically, that the area is unchanged. The constancy of the periphery, then, of each of these figures entails the condition of an approximate constancy of the area. Here, then, we have the skeleton work of a medium which, looked at in two directions, is incompressible and inextensible, but is exchangeable in area, and is freely extensible in any opposite directions provided you allow it to shrink in the perpendicular direction. Well, now, I say, put a gyrostat into each of those squares, and you have all that is wanted to fulfil almost any conceivable condition that I put before you. (A gyrostat was set going, and some details of its action explained.) Well, now, the upshot of it is simply this: imagine a gyrostat, such as this, in each one of the squares of this web; suppose the speed was infinitely great—a million million million times per second—it would take some thousands or millions of years to pass before the application of a torque would break down a wire by twisting it or turn it one degree. You can make it as immovable as you please by imagining the angle of the flywheel to be so great, and there is nothing to curb our

imagination in this respect. (A gyroscope was shown, and its action described in detail as illustrating the same ideas).

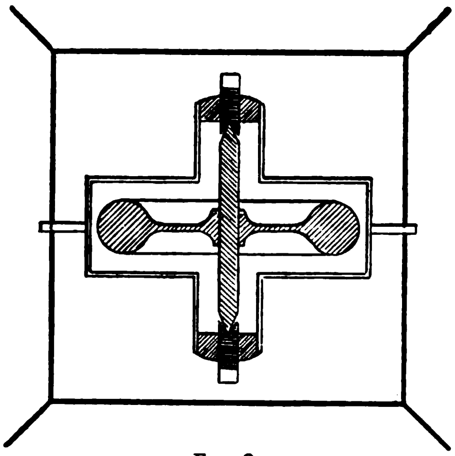

FIG. 2.

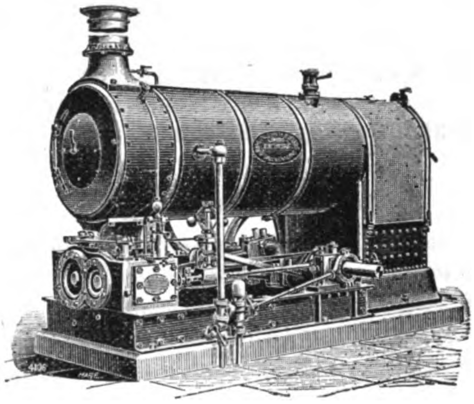
I shall not detain you more than two or three minutes longer, just to show that we have a specially elastic solid in the structure. Do not imagine that a structure of this kind, gross as it is, is necessarily uninstructive. Look at the structures of living things, look at the wonderful tactics in the structure of organic beings, think of what we have to explain in electricity and magnetism, and allow at least that there must be some kind of matter. We cannot suppose of dead matter to be without form and void, and without any structure. There must be molecules of some shape, they must have some relation to one another, and surely we can imagine the things exist though we may be unable to perceive it. I do not admit that this is playing at theory, but it is helping our minds to think of possibilities, so that here is a structure that can be produced which is a perfect liquid, that is an incompressible, frictionless liquid, without any gyrostatic arrangement when no gyrostatic arrangement is given to it. Now, consider for a moment the effect of introducing gyrostats into each of these squares. Each of the squares becomes immovable, and you get a set of elastic threads stretched to the corners of immovable cubes—immovable in rotation, but perfectly free to take translatory motion. There you have a body, then, which you need not distinguish from an ordinary elastic solid, so far as translation effect, so far as motion as a whole is concerned, but which, if you try to turn it, will not absolutely resist, but will only admit of turning by stretching of the connecting elastic bands; it will not be immovable in respect to turning, but it will be balanced by a constant couple, with a constant degree of rotatory displacement. Thus, upon this solid, the effect of a constant couple is not to produce continued rotation, but to produce a balance. Constant displacement of that balance might last for millions of years if the rotational moment of momentum is but great enough. Lastly, I should just say briefly this, that the rotational quality of ether in iron must be enormously less than in copper or in air. The total rigidity due to elastic action and gyrostatic effect in all non-magnetic bodies is the same. The total rigidity of ether is the same in all non-magnetic bodies. In iron it is less through less gyrostatic contribution with equal elastic contribution to the rigidity. Those conditions fulfil exactly what we want for the relation of ether between air and iron inside the helix of an electromagnet. But now we are only landed in an absolutely immeasurable difficulty. We have a strange solid forced between the bodies connected with the system. Why is it that they do not balance themselves in the solid. How can there be a solid giving rise to these prodigious effects, and as when copper will fall down at the rate of a quarter ampere per second until it gets away free, and so on? How can it be that this prodigious effect is passed through a solid, and yet other forces be perfectly free to move within that solid? I can only say that we have done all we can to think out this subject, but it merely gives us a dynamical theory of one part of it. The electrostatic part, our first love, has been left out in the cold, though I have spoken of it two or three times; but we do not touch it or get near it in any of this doctrine, and we do not get the mutual attraction between iron and iron, nor near the motion of the body that demonstrates this force—we only get the conclusions which mathematical theory lead us to believe exist. I must give up saying that the difficulties are so great by way of forming a comprehensive theory that we cannot imagine a single thing that leads us towards a conclusion. We cannot imagine it, but this time next year or this time 10 or 100 years it will probably be as easy to think we can understand that glass of water as to understand the solids that are now incomprehensible; the mysteries will be no mysteries at all, but the scales will fall from our eyes, and we shall be able to look at things in a different way than now. I must ask you to pardon me for bringing it to such a conclusion, that we really know nothing about this grand subject which constitutes the province of the Institution of Electrical Engineers.

Votes of thanks were accorded to Mr. E. Graves, the retiring president, and Sir W. Thomson for his address.

1888.

We continue our *résumé* of the work of 1888, but owing to the space devoted to Sir W. Thomson's address, are compelled to leave the conclusion to another issue.

MESSRS. RANSOMES, SIMS, AND JEFFERIES, LIMITED, of the Orwell Works, Ipswich, who were among the first to adapt their engines to the requirements of the electric light, are supplying a most extensive assortment of engines of various types specially adapted for driving electric machinery.



Their compound stationary engines, of the "Undertype," of which we annex an illustration, have given the most excellent results, both as to economy in fuel and stability in work. The automatic governor expansion gear with which these and all Messrs. Ransomes' engines may be fitted has been lately still further perfected. The cut-off is varied by the action of the governor between 0 and 75 per cent. of the stroke, according to the actual load on the engine; and the exact amount of steam necessary to do the work required being admitted at full boiler pressure up to the point of the cut-off, the entire benefit of the principle of expansion is obtained. In addition to the advantage arising from the economy effected in the fuel consumption by the adoption of this gear, the speed of the engine is maintained practically constant under the greatest possible differences of load, the variation in the number of revolutions in no case exceeding about 2 per cent. from the mean.

For temporary purposes Messrs. Ransomes' portable engines can be highly recommended. In addition to the front platform, which is already well known to our readers, they have lately arranged a platform extending from the firebox end, which enables any stock engine to be used, thus ensuring prompt deliveries. One of these engines carrying a dynamo was used with great success during the dark winter afternoons at the Ipswich Cattle Market by a local auctioneer, enabling him to conclude the sale of his stock in one day, greatly to the convenience of himself and his patrons, and with a consequent saving of time and cost. Besides having supplied engines for driving electric light plant in this country, Messrs. Ransomes, Sims, and Jefferies have during the year delivered engines for similar work to France, Italy, Russia, India and Australia.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed " Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of Mr. E. Graves, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. Wollaston, M.D., F.R.S., *and* Sir Humphry Davy, F.R.S. *The portraits of* Prof. D. E. Hughes, F.R.S., *and of* Dr. J. Hopkinson, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

THE PRESIDENTIAL ADDRESS.

The selection of Sir Wm. Thomson as the first president of the Institution of Electrical Engineers was a happy one, inasmuch as he is the greatest living exponent of electrical, we might say physical science. The new title of the society is comprehensive enough to include every class of electricians, whether they be devoted to the pure or the applied branches. History contains very few names equally, nay superlatively, eminent in both branches, and that of Sir William Thomson stands almost, if not quite, at the head of the short list. We have during our connection with electrical literature been brought into contact perhaps more extensively than most people with men who have been students at Glasgow under Sir W. Thomson, and men who in America have worked with Edison. We never yet remember to have met one of Thomson's men who had not the profoundest admiration for the master, nor one of Edison's who was not prepared to swear an affidavit that he is the only inventor under the sun. In both cases there is one and none other. Sir William's dicta may be, and often are, quite incomprehensible to the ordinary mind, but they are received, like the laws of the Medes and Persians, as perfect—hence requiring no change. It is to him that the younger physicists look, and if their theories or their work meets with his approbation, they feel confident that the ultimate conclusion about the work will be that it is good. There is a spirit of emulation amongst his students that has led and is leading to important investigations in many branches of physical science. The professors of the younger universities are largely recruited from Glasgow. The mere fact, then, that the Institution has such a president should induce the members to contribute during his period of office, as far as they can, papers and information which shall inaugurate a new era of usefulness of the society.

Coming now to the immediate subject of this article, there are three points in the presidential address to which reference must be made, but only upon one of these shall we dwell at any length. There is the wonderful and highly imaginative theory put forth for those given to discussing and thinking about the transcendental, to reflect upon, but this portion of the address is not for the multitude. We take it for granted that the theory is put forward only as a tentative one, and, considering this, we reflect that the ancient Greeks, possibly the Egyptians and Chaldeans also, possessed wonderful theories about our solar system and the motions of the bodies contained therein. Since those olden times, however, the suggestions of Newton and others have somewhat simplified the older theories, and we may imagine ourselves in relation to electrical theories to be somewhat in the position of the Greeks with regard to astronomical problems. The

Digitized by Google

theories advanced have a value, but as knowledge advances these theories will give place to new ones, and undoubtedly the hope of every student is that the theory which is to come will be simpler than the one that has preceded it.

"There is more in heaven and earth, Horatio,
Than is dream't of in your philosophy."

No doubt Shakspere was right, as was the Psalmist in his physiological surmise, that we are fearfully and wonderfully made. It is, however, these fearful and wonderful theories that accord best with certain phenomena, and have been deduced therefrom by the best trained investigators this earth has ever known.

The second point to which we would direct attention is the eulogy upon the work of Mr. Oliver Heaviside. This may not be the best place to record certain facts in connection with Mr. Heaviside's writings, but we venture to do so for many reasons, not the least of which is the pleasure we feel in having our views corroborated by so eminent an authority as Sir W. Thomson. Putting aside the papers that appeared in the *Phil. Mag.*, the articles that were given in the *Electrician* were given in spite of the most strenuous opposition by the proprietors and every member of the staff, except the late editor. Hence possibly the singularity of the sudden cessation of the articles which has so frequently been remarked upon that the reason may not be uninteresting. Previous to Sir W. Thomson's acknowledgment of the magnitude and value of Mr. Oliver Heaviside's work, Mr. Preece had called attention to certain parts of it as worthy of the closest attention, and forestalling later workers in the same direction.

The third and most important point to ordinary mortals is the advice given to parents and such as would enter the profession of electrical engineers. Reference was made to this advice by one of the subsequent speakers, but Sir William's advice was perfectly sound and just. The amount of electrical knowledge required by the ordinary electrical engineer can be obtained in a few months. That knowledge, and that time, has nothing whatever to do with the student desirous of entering into the domain of pure science and theoretic investigation or investigation into theories. Electrical engineers do not care a dump (use any other expression if this is not suitable) about theories: they want something that will assist them to gain bread and cheese. Professors are not too well paid in this country to make men very envious of their profession, and if they were better paid the number of openings for young aspirants is not so great as to tempt many to depend upon getting into one for a livelihood. We should like to see professors, like the woman's best bonnet in its band-box: they should be highly honoured, well paid, worked moderately, and kept from the Patent Office and consulting work. At the present time we give them butlers' wages, and shut our eyes to their efforts to divide their labours. Young men may accept Sir William Thomson's dictum in this respect: Get a good general education as a foundation, never mind about Latin or Greek, prefer German and French. Upon the general superpose the special. Study the higher branches of mathematics, pure and applied. A good knowledge of mechanical and civil engineering, especially mechanical, should be a *sine qua non*, and then comes the special electrical knowledge that can be applied in practice.

CORRESPONDENCE.

BATH ELECTRIC LIGHTING.

To the Editor of the Electrical Engineer.

Sir,—The tenor of Mr. Massingham's letter affecting my company in your last issue and the sympathetic comments thereon in the electrical journals being calculated to create the impression among local authorities throughout the country that they are likely to be denied the benefit of competition in determining to whom they should allot the areas within their jurisdiction, I shall be obliged by your kindly giving the widest publicity to the announcement that the House-to-House Electric Light Supply Company, Limited, whose engineers have hitherto constructed the only central electric lighting stations for the distribution of electricity throughout an extended area by means of underground mains, is prepared to place its experience in both electric light supply and central station construction at the disposal of local authorities everywhere in the United Kingdom.

The House-to-House Company, as its name implies, has no local predeliction whatever beyond the usual commercial inducements, and it will be prepared either to apply to the local authorities for permission to apply to the Board of Trade to undertake the business of supply within their areas on its own account, or in conjunction with local capital, or to erect for local authorities or independent supply companies central stations on the model of its own at Kensington, which is, by general admission, the most perfect of its kind.

To this end my company endeavours as far as possible to watch the progress of central station development in all towns in the United Kingdom which in virtue of their population present a promising field for the electric light; and its letter to the Bath City Council was prompted by the report of the proceedings of that body, from which it appeared that a contract had been somewhat reluctantly concluded with Mr. Massingham for street lighting only by means of overhead conductors on the faith of representations to the effect that the present position of electrical science did not permit of the work being accomplished by means of underground mains.

Believing, as my directors do, in the advantage to the public of being supplied under the Electric Lighting Act, which not only requires an underground service, but secures rights to the consumer, with corresponding obligations on the part of the supplier, they felt that in these circumstances they would be best protecting the interests of the ratepayers of Bath by applying to the Corporation for permission to apply to the Board of Trade to light a limited area of the city for a limited period under a license tenure; and although the unfavourable editorial comments of the electrical journals on their proceeding have been brought to the notice of my directors, they regret to say they can see no reason to induce them to abandon the step they have taken.

We cannot attempt to justify our ignorance of Mr. Massingham's claims to the consideration of his fellow

Digitized by Google

citizens. All that we knew about him at the date of our letter to the Corporation of Bath was that he was a most respectable boot and shoe maker in that city, and all that we have since learnt on his own admission is that, so far as electricity is concerned, he is "only an enthusiastic admirer of the light of the future."

My directors venture to believe, however, that such qualifications are inadequate for the proper discharge of the responsibility of undertaking "to introduce electricity into several towns of the West of England"; but, be this as it may, they trust that if they should follow Mr. Mas singham in extending their operations in the future to such places, the electrical press will not in that event bestow its support on him and withhold it from them.—Yours, &c.,

H. St. John Winkworth,
Secretary House-to-House Electric Light Supply Company, Limited.
117, Bishopsgate-street, London, E.C.

ELECTRIC LIGHTING.

The following letter from Mr. Hammond has appeared in the *Times*, and was followed by one by General Webber in continuation of this subject, both being dated Jan. 10:

"Sir,—Your admirable leading article in to-day's issue so completely sums up the situation with regard to the electric lighting of the metropolis, that there is hardly anything left for me to reply to in the communications of Mr. Erskine and Lord Crawford.

"I should like, however, to have the opportunity of pointing out in reply to the first gentleman that my letter was by no means intended to be an attack upon the electric lighting industry, in which I am personally so closely concerned; nor is Lord Crawford correct in assuming that my wish is, while advising that no monopolies should be given to others, to seek one for myself. I am, however, quite in accord with both these gentlemen in the views they express that no extensive electric lighting can take place in the metropolis or elsewhere except under the sanction of provisional orders, and I am confident that this will be the form of tenure which will eventually attract capitalists to the industry, though it is curious to note, as an argument upon the other side, that Lord Crawford's own shareholders have subscribed upwards of half a million sterling without the security of either a provisional order or a license, and that they have expended the greater part, if not all, of this sum in the execution of works which at the moment depend for their continuance solely upon the sufferance of the owners of private property which their overhead mains traverse; and that another company has also succeeded during the past six months in obtaining a like sum without any Parliamentary powers whatever.

"Your correspondents are both wrong in supposing that I advocate for permanent work a tenure by license in preference to a tenure by provisional order.

"My main contention was stated in my first paragraph, which I venture to repeat, as follows:

"'1. No district lighting has up to the present time been carried out in the metropolis of so satisfactory a nature as to warrant the Board of Trade and the local authorities in proceeding at once to the apportionment of the metropolitan area by means of provisional orders, and no district lighting whatever has been carried out *over an extended area* by means of *underground mains*—the mode of distribution contemplated by the Act.'

"No refutation is made by Lord Crawford's statement that an extensive system of overhead supply is already in the field, nor by Mr. Erskine's statement that his company has admirably performed (which I am perfectly ready to grant) some excellent lighting over a very limited area.

"That district electric lighting can be carried out over an extended area by means of underground mains has been set at rest by the work of the Eastbourne Electric Lighting Company, where such a supply system has been in operation for the last six years, and where the mains are some 20 miles in length.

"My sole object in writing to you was to make known through your columns that the Board of Trade distinctly denied the truth of the assertion which Lord Crawford made on the 21st of December last, and I am surprised that, in spite of the official denial quoted in the Board of Trade's letter of the 29th of December, Lord Crawford, on the strength of a newspaper paragraph which he refers to as 'apparently communicated officially,' should still persist in repeating his misstatement.

"It is most important that at this juncture the local authorities in the metropolis who are seeking to discharge their responsibilities under the Act should be made aware of the real state of the case, so that they might not refuse consideration, as some of them have hitherto been inclined to do, for licenses for limited areas, on the ground that they would not in any case be entertained by the Board of Trade.

"I feel, indeed, that in the interest of the industry and of the public generally, it is desirable that the utmost publicity should be given to the fact that, at present, at any rate, all the Board of Trade has decided is that such applications for licenses as those which relate to extensive areas in the metropolis are inadmissible, but that the Board of Trade is prepared to consider on their merits the applications of electric light supply companies for licenses for limited areas.

"It is quite true that I assume that the powers granted under provisional order over a certain area will practically preclude the granting of any competing power over the same area, although I am, of course, well aware that for the purpose of weeding out incompetent companies the Legislature has expressly provided that powers may be granted to more than one company concurrently over the same district.

"While recognising that the powers to be conferred under the Act do not constitute a monopoly in terms, I venture to believe that they will prove to be a monopoly in fact, and the experience of the gas companies, which resulted, after years of waste and confusion, in the system of 'districting,' is to my mind conclusive on the point. All that my argument assumes is that the practical inconvenience and expense of duplicating mains in the same street, and the difficulty of inducing another company to enter upon the unoccupied portion of an area the best of which has already been appropriated, will afford an incompetent company a practically unlimited opportunity for bungling. Indeed, I venture to say that it hardly follows, as you allege, that, because an area is occupied by wires and plant in working order, the company is doing its work efficiently. Consumers in one area might be served by a company whose light was normally inefficient and continually failing, while consumers in another might be served by a company dispensing a bright and continuous light.

"With regard to the possible action of the county council in the matter, I quite concur in the view that the industry is safe in the hands of the Board of Trade, but I have read nothing in the letters of your correspondents causing me to alter my opinion that the interests of the public generally, and of the electric lighting industry as far as the lighting of the metropolis is concerned, will be best conserved by the granting of a limited number of licenses for short terms and for limited areas before dealing with the allotment of the whole of the metropolitan areas by provisional orders with a 42 years' tenure.

"The difficulty of obtaining capital does not arise, because there are amply sufficient funds in the hands of the supply companies already in existence to efficiently carry out the work."

"Sir,—Your leading article of this date on the electric lighting industry will be read with feelings of gratitude by all who have studied the subject.

"The Paris Municipality, in granting concessions to six *permissionnaires*, has approached it in the same spirit—namely, quoting your words, 'We do not want oppressive monopolies, but we cannot afford to throttle enterprise by stipulations which discourage investors.'

"They go further, and, having studied its difficulties, will not allow the *permissionnaires* to spend in competing with one another the money that is subscribed by the public for remunerative works. At the same time they

Digitized by Google

provide for a revision of the rates of charge for electricity to the consumers every five years, subject to a scale that slides with the profits.

"I trust you will permit my adding to the information you have already received that, although none of the provisional orders taken out in 1883 are now in force, there is one in operation, which was obtained by the Chelsea Electricity Supply Company, and confirmed by Act of Parliament in September, 1886.

"When the 'tenure' was extended last year from 21 to 42 years, that company, which had previously failed to raise the necessary capital, found no difficulty in doing so. They immediately made contracts for buildings, machinery, and a system of undergound distributing mains, and those contracts are in full course of execution.

"They have also been for some time breaking up some of the streets of Chelsea, and laying down mains in a 'thoroughgoing fashion.'

"The system they have adopted affords sufficient access to the cables for the repair of the insulation and the removal of the cause of leakage, without having again to disturb the streets, and without any necessity for accommodating the wires in tunnels accessible to workmen."

ELECTRIC LIGHTING OF THEATRES.—III.

Savoy Theatre.

The installation at this theatre was designed and carried out by Messrs. Siemens Bros. in 1881, and is still in charge of one of their engineers, Mr. Nebel, who has worked out a very perfect system of theatre lighting by electricity. Pending the laying down of a permanent plant, with which to light the Savoy Mansions Hotel as well as the theatre, the original plant has been removed from the iron shed, which formerly stood where the hotel now is, to the basements of the buildings between the Savoy Theatre and the Embankment. The whole of the theatre—both before and behind the proscenium wall—is lighted electrically; but gas is still used to some small extent in the passages, and also in the auditorium in order to warm it.

The plant consists of one Robey and two Marshall portable engines of 20 h.p. nominal each, and of three Siemens' dynamos. The Robey engine is driven at 125, and the Marshall engines at 95 revolutions per minute, with a steam pressure of 75lb. The dynamos are of the B 11 type, and are compounded to have a constant E.M.F. of about 90 volts at the 850 revolutions per minute at which the engines drive them by means of belts and counter-shafting; they can give current up to 500 amperes each. One of the dynamos, driven by the Robey engine, does the whole of the lighting not connected with the performance. A second, driven by one of the Marshall engines, lights the battens, and the third, driven by the remaining Marshall engine, lights the auditorium, sidelights and float. The regulation of the engine is entirely by hand; the driver is told to keep the pointer of the speed indicator at a certain mark, and has, further, a pilot lamp to guide him. There is no possibility of the house being plunged into total darkness by any breakdown of the machinery, as the engines and dynamos divide the load, and are quite independent of each other. The lamps used throughout the theatre are of the Edison-Swan pattern, take about 0·65 amperes at 88 volts pressure and give out 16 c.p. A large proportion of the lamps have lasted considerably over the estimated 1,000 hours. All the fittings of the auditorium and the front of the house are the same as those put in originally, and are by Messrs. Faraday and Son; they are very artistic and add much to the beauty of the decorations. The auditorium is lighted by three tiers of brackets—each bracket supporting three glow lamps in frosted glass shades — which run round the inside of the auditorium. The lowest or balcony tier contains 12 brackets; the second or circle contains 22; and the highest or gallery, 16; so that, in all, 150 lamps are used to light the auditorium. The front of the house includes the refreshment bars, corridors, offices, etc.; a large number of single lamps are used in this part of the house, but there are also some elegant electroliers in the bars and cloakrooms. In all, 165 lamps are used to light this part of the house.

The stage is provided with six battens, 20 lengths of sidelights and the float. Each batten has two rows of lamps, the one row containing 90 coloured, and the other the same number of white lamps. Each batten is provided with a separate switch, so that any of them can be lighted independently of the remainder, and there is also a two-way switch for changing them all simultaneously from coloured to white light, or *vice versâ*. The sidelights, which can be equally well used as ground lights, consist of 20 lengths. Each length contains two rows of eight lights—the one coloured and the other plain. Each length has a flexible cable, containing the going leads to the coloured and white lights, and a middle common return lead attached to it. The cable ends in three copper plugs fastened to a small block of wood, and each plug is insulated from the others and connected to one of the leads. Round the stage, sockets are let in corresponding to these blocks with plugs, and connected to the sidelights switchboard. If, then, a length is wanted at any particular place, all that has to be done is to press in flush with the stage a block into the nearest socket and place the length attached in the required position. Both the battens and the sidelights had formerly in circuit variable resistances and switches for regulating the light from them so that eight degrees were obtainable from each, but at present these resistances are not in use. The float contains 70 white lights, and, by resistances and an eight-way switch, as many degrees of light are obtained. Each music-desk in the orchestra is fitted with a lamp having such a resistance permanently in its circuit that, when they are turned on in dark scenes, they give a faint red glow sufficient to enable the musicians to read their music, but made, by shades, quite invisible to the audience. The dressing-rooms and passages behind and beneath the stage are lighted by 145 more lamps: in each dressing-room the mirror has attached a glow lamp on either side of it, and this is found a great convenience for making up, etc., as the artists can have their faces close to the mirror and to the light without danger or discomfort.

The whole of the stage fittings are on an incombustible system designed by Mr. Nebel. The battens and sidelights consist of strips of sheet iron about $\frac{1}{16}$in. thick and 12in. wide, and of the required length. To these backs are fastened, at intervals of 24in., porcelain insulators carrying two copper strips, each $\frac{1}{16}$in. thick and $\frac{3}{8}$in. wide running the length of the sidelights or batten, at about $\frac{3}{4}$in. from the sheet iron and two inches apart. Between these copper leads any required number of lamps at any required distance apart can be rapidly inserted by means of specially designed porcelain holders. These holders are so designed that lamps can neither be shaken out of place nor short-circuited.

The advantages of the electric lighting of the stage considered specially important in the Savoy Theatre are the absolute safety from fire; the easy manipulation and greater range of regulation of the light, and, as a consequence, a considerable reduction of the staff of gas men; the greater range of disposition of lamps, as they may be put as close to the scenery as is required; the prompt working of changes; the possibility of completely extinguishing the light on the stage; and, lastly, the important advantage to the singers of the absence of the overpowering streams of heated air and products of combustion from the argand burners in the float. The management experience all the advantages of lighting the auditorium and front of the house we have enumerated in previous numbers, and we may mention, as an important point, that the theatre has only *once* been redecorated since the opening in 1881, and that a *substantial* diminution in the rate of insurance is obtained by the management from the fire offices.

Mr. Nebel considers that the dusting or washing of the glow lamps every four weeks is the only disadvantage they meet with, but we may remark that other managements have considered that the reduction in trouble in cleaning the globes surrounding the lamps used is immensely in favour of electricity over gas.

Two arc lights in the carriage entrance are also run off the same plant used for the incandescent lighting.

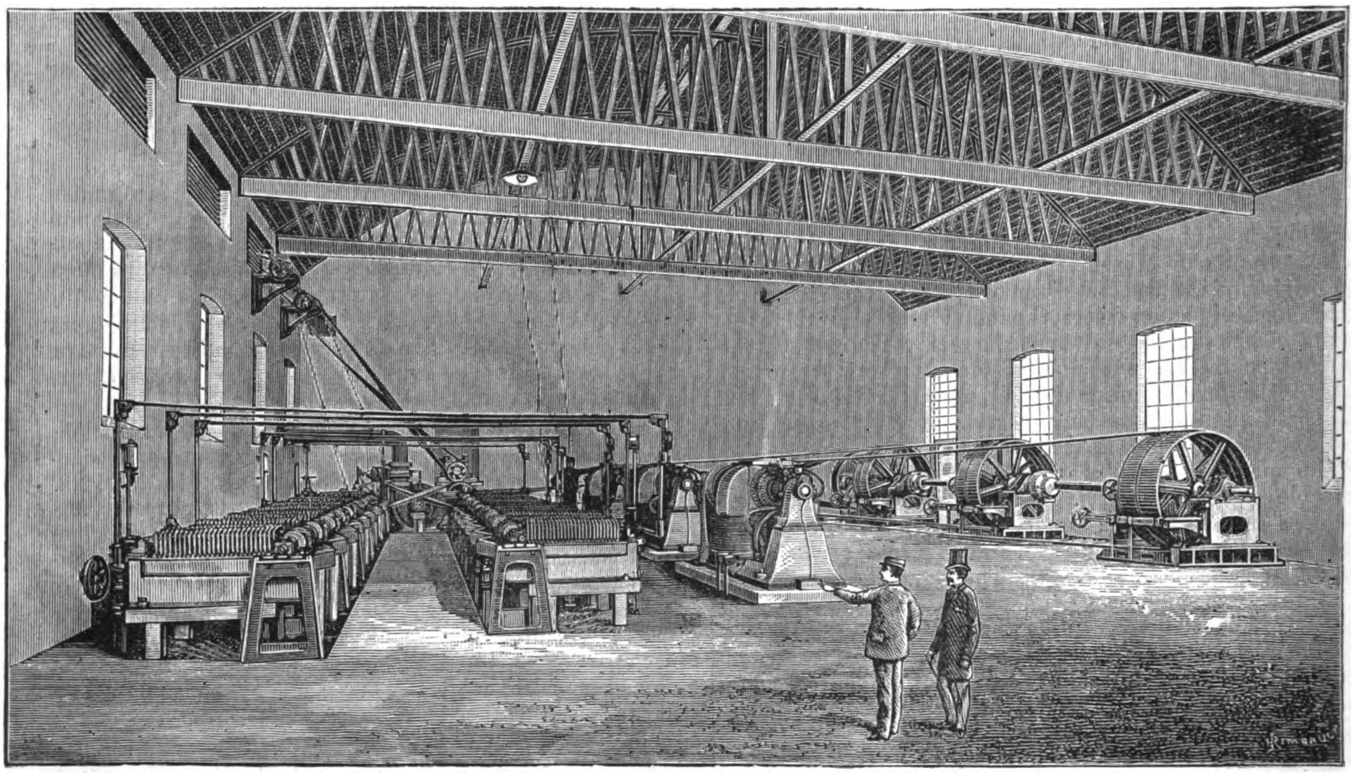
THE HERMITE ELECTRO-CHEMICAL BLEACHING PROCESS.

A description of this process will be found in our issue of May 11, 1888. We are now able by the accompanying illustration to represent the arrangement of machinery for this process lately installed at Messrs. Evans and Owen's Paper Works, near Cardiff. The plant is capable of producing equal bleaching effect to two tons of bleaching powder per 24 hours, and was constructed and installed by Messrs. Paterson and Cooper to the order of the Hermite Company. Briefly described, the Hermite process consists in manufacturing a solution of high bleaching power by electrolysing an aqueous solution of magnesium chloride. The salt is decomposed by the current at the same time as the water. The nascent chlorine, liberated from the magnesium chloride, and the nascent oxygen, liberated from the water, unite at the positive pole, and produce an unstable oxygen compound of chlorine of very high bleaching power. The hydrogen and the magnesium go to the negative pole; this last decomposes the water, and forms magnesium oxide, whilst the hydrogen is disengaged. If in this liquid coloured vegetable fibre is introduced, the oxygen compound acts on the colouring matter, oxydising it. Chlorine combines with the hydrogen to form hydrochloric acid, which finding itself in the presence of magnesium in the liquid, combines with it and forms the initial chloride of magnesium. Thus a complete cycle of changes goes on so long as the electric current acts on the solution in the presence of colouring matter. The cycle is a perfect one, in which there are four elements: the electric current, chloride of magnesium, water, and the colouring matter. Only two of these elements are used up whilst bleaching: the electric current and the water. The magnesium chloride serves over and over again. There is only a simple displacement of molecules, and the chloride acts as a vehicle to discharge the nascent oxygen on the colouring matter. Mr. Eugene Hermite, the inventor of he process, has found, after prolonged research, that it is magnesium chloride which of all chlorides gives the only commercial and complete results.



The plant at Messrs. Evans and Owen's works consists of 20 electrolysers arranged in two rows, through which the solution of magnesium chloride is constantly circulated. Each electrolyser consists of a galvanised iron box open at the top and with a perforated pipe at the bottom. The box is filled with the electrodes, which consist of a series of platinum plates connected to the positive pole of the dynamo, and a series of circular zinc plates interspaced with the platinums and connected to the negative pole of the dynamo. The solution is admitted at the bottom through the perforated pipe, and overflows the sides of the box, passing in between the plates, and, being decomposed, then falls into a cement tank underneath. From this bottom tank it is taken by means of a 12in. centrifugal pump into the tank above, and is ready to pass through the electrolyser again according to the strength required. The top tank is a large, egg-ended boiler, and is connected to each electrolyser by means of a rubber pipe and cock. It is from the top tank that the solution is pumped over to the bleaching mill, a distance of some 50 yards, by means of an 8in. centrifugal pump, where it is received in tanks, from which it is drawn as required. The method of working is very simple; the pulp ready to be bleached being in a potcher, the electrolyser bleaching solution is run in, and the washing drum kept working. As the solution passes through the pulp its bleaching power is exhausted, and it is returned, by means of a pipe, to the top tank, from which it originally started, and from whence it again passes through the electrolyser and is regenerated. The amount of solution remaining in the pulp after bleaching is recovered by a system of displacement in drainers or by means of a press plate. The current is supplied by three of Paterson and Cooper's Phœnix shunt-wound dynamos, each giving a current of 1,000 to 1,200 amperes, with a difference of potential at the terminals of 40 volts. The electrolysers are arranged in series, eight on each of two dynamos, and four on the other. This has been so arranged that another four may be added when required. Each circuit has an ammeter and voltmeter connected. The dynamos are driven by a compound condensing engine of the tandem type, capable of indicating 300 h.p., the amount actually taken up at present being 200 h.p. An important part of the plant is that for the preparation of the magnesia necessary for keeping the solution basic. It consists of a vertical tank fitted with a stirrer, in which lime milk is made. This is run from thence into a shoot, discharging into any one of three vertical tanks, each fitted with a stirrer. These tanks are all placed above the main tank supplying the electrolysers, so that by merely opening a cock the "base," when prepared, can be run down at will. The three vertical tanks are partly filled with a solution of magnesium chloride, and then filled to the top with the lime milk. The lime throws down the magnesia, the calcium chloride which

Digitized by Google

remains is syphoned off, the magnesia being then washed twice is ready for use. The cost of bleaching by this system compares very favourably with the old process. The fibres bleached are not deteriorated in strength to anything like the same extent as with bleaching powder. There are many modifications of the process for the bleaching of linen and cotton yarns, piece goods, etc., and also many different forms of apparatus, which are the subject of numerous patents in the names of Messrs. Hermite, Paterson, and Cooper in England and abroad.

The plant has been manufactured and erected by Messrs. Paterson and Cooper, to whom we are indebted for this description and illustration, under the personal superintendence of Mr. Hermite. Several large paper manufacturers have adopted this process.

ELECTROLYSIS OF COPPER SALTS.

BY ALEXANDER WATT.

(Continued from page 35.)

16. *Nitrate of Copper.*—A bath was formed by dissolving 60 grains of the neutral salt in eight ounces of water, and the solution was electrolysed with the current from one cell, a pure copper anode and a steel cathode being employed as in the former experiments. Soon after immersing the steel plate it became coated with a film of copper, which, however, was only partially adherent. After a few minutes the anode was coated with a film of oxide, while a whitish salt floated in the liquid in flocculent particles, rendering the fluid turbid after a time. Two drops of nitric acid were now added to the bath, which immediately became clear from the white salt having become dissolved. No hydrogen was given off at the cathode. The nitrate of copper seems to be the best of the metallic nitrates for yielding to the action of the current, that is so far as deposition of metal is concerned. It was next determined to try if a stronger current, with agitation of the cathode, would cause the anode to dissolve more freely; but this modification of the conditions did not secure such a result, for it was found that the anode (which had been cleaned by dipping in hydrochloric acid) again became coated with an orange-yellow film of oxide. There was a moderate evolution of hydrogen when the two cells were used. A new solution of the nitrate, still more acid than the preceding, was next tried, but it was found that the anode only remained clean and bright at the two lower corners, while the remainder of its surface was coated with oxide. When this latter solution was tried in a very diluted condition, and the steel cathode kept briskly in motion, the deposited copper was found to adhere tolerably well.

17. *Nitrates of Copper and Potassa.*—Small quantities at a time of nitrate of potash were added to the foregoing solution, to see if this combination would favour the adhesion of the deposited metal to a steel surface. The result, however, was not satisfactory, for the various deposits obtained were less adherent than those obtained in the simple nitrate bath; at the same time the anode became strongly coated with a film of red oxide of copper, which attached itself firmly to the copper surface.

18. *Citrate of Copper.*—A solution of this salt was prepared by dissolving recently precipitated and moist hydrated oxide of copper in a strong and hot solution of citric acid. The liquid was then set aside to cool and settle, after which the clear liquor was poured off, and diluted with about twice its volume of cold water. A clean strip of steel immersed in this solution became promptly coated with copper, which was firmly adherent and of very good colour. The current from a single cell was then tried, when a steel plate received a prompt and very bright coating of copper, which, on being severely scoured with moist silver sand, proved to be very adherent. The brightness of the deposit from this solution might render such a bath useful for coating small fancy articles of steel or iron. On immersing a clean strip of zinc in this solution, it quickly assumed a yellow colour, owing to the deposited copper at once alloying itself with the zinc, forming brass. The same result was obtained when the current from one Daniell was used.

19. *Saccharate of Copper.*—A solution of this salt was electrolysed with the current from two cells, when a very tardy deposit was obtained upon steel, which was fairly adherent.

20. *Ammonio-nitrate of Copper.*—With the current from two cells, a bright deposit of copper slowly formed on a steel plate, which, however, was non-adherent. A bright green deposit formed on the anode, apparently hydrated oxide of copper, which, however, did not become dissolved in the liquid.

21. *Chloride of Copper in Hydrochloric Acid.*—Crystals of chloride of copper were added to an ounce of commercial hydrochloric acid, and the mixture stirred for several minutes, after which the liquid was poured off the undissolved salt and electrolysed with the current from two cells, the object being to ascertain whether a crystalline deposit could be obtained from this solution. Copper electrodes were used, and the moment these were immersed in the liquid a dark salt was thrown off from each electrode, which in a few seconds rendered the solution almost black. After a short time a spongy deposit of copper appeared at the cathode, which rapidly increased in bulk, but there was no disposition for the metal to assume a crystalline form in this concentrated solution. The solution was next diluted with about six times its bulk of water, and a platinum wire employed as the cathode, which soon received a spongy deposit of the metal, but beyond this no result of an interesting character was obtained.

22. *Pyrophosphate of Copper.*—A solution of this salt was prepared by digesting recently precipitated and moist carbonate of copper (washed in cold water) in a strong and warm solution of pyrophosphate of soda. The liquid was afterwards moderately diluted and electrolysed with the current from one cell, when a bright deposit of copper was received upon a steel plate. A solution prepared from this combination might be useful in cases where a bright deposit of copper is required. The anode kept very clean in this bath.

23. *Carbonate of Copper in Chloride of Barium.*—A solution was prepared by dissolving moist carbonate of copper in a strong solution of barium chloride, and the resulting solution, which was of a pale blue colour, was then diluted and electrolysed with the current from one cell. Deposition of copper took place very quickly, and the cathode (a steel plate) at first became coated with a bright film, but this after a few moments became dull and of a dark brown colour. The liquid had to be diluted very considerably, and the anode surface greatly reduced, before a uniformly bright film could be obtained; in fact, even when the liquid was diluted with at least eight volumes of water it was necessary to immerse only half a square inch of anode to a cathode surface of about four square inches. The deposit, under the modified conditions referred to, was exceedingly coherent, but after about 20 minutes' immersion the film assumed a dull appearance.

24. *Salicylate of Copper.*—A bath was prepared by digesting moist hydrated oxide of copper in a hot solution of salicylic acid, by which a liquid of a rich olive-green colour was produced. Electrolysed with the current from two cells, a deposit of copper slowly formed upon a steel surface. There was no evolution of gas, and the anode remained clean.

25. *Lactate of Copper.*—To form a solution of this salt, moist hydrated carbonate of copper was gradually added to lactic acid, in which it became freely dissolved in the cold. The resulting solution was afterwards moderately diluted with water, and then electrolysed with the current from a single cell, when it was found that a film of copper promptly formed upon a steel plate, which proved to be very adherent.

26. *Borate of Copper in Hydrochloric Acid.*—A quantity of borate of copper was first prepared by adding a solution of borax to one of sulphate of copper, and the resulting precipitate was then well washed. A portion of the precipitate was next dissolved in strong hydrochloric acid, and the concentrated solution, which was of a bluish-green colour, was electrolysed with the current from one cell, when dark brown spongy copper quickly formed on the

Digitized by Google

cathode. At the same time a copious white deposit formed on the anode and dropped from the plate in solid flakes. Some of this white deposit was put into a test-tube filled with hot water, when it fell to the bottom of the vessel with great rapidity, and in its passage through the liquid turned to a full orange colour. A further portion of the white deposit was next washed in *cold* water, when it assumed the orange colour, as before, immediately on coming in contact with that liquid, which evidently altered its condition. The density of this substance, doubtless a suboxide of copper, was certainly remarkable. A small quantity of the white powder left in water for a few days acquired the red colour of the suboxide. The solution was next diluted with about six volumes of water; a strip of steel was then immersed in the liquid, when it quickly became coated with an adherent film of copper. With the current from one cell, the deposit was also firmly adherent, but turned dull after a time, and of a dark colour, having a purplish tone.

27. *Borate of Copper in Cyanide of Potassium.*—Borate of copper was added to a solution of cyanide of potassium, in which it became slowly dissolved. With the current from two cells a steel plate received a very tough and adherent coating of copper.

28. *Borate of Copper in Tartaric Acid.*—Borate of copper was gradually added to a warm and moderately-strong solution of tartaric acid, and the whole stirred until the copper salt was dissolved, when the solution, which was nearly colourless, was tried with the current from a single cell. On immersing a steel plate, it became at once coated with a film of copper, which very firmly adhered to the plate. The anode kept quite clean in this bath.

29. *Borate of Copper in Acetic Acid.*—A solution was prepared by dissolving the copper salt in strong acetic acid, the solution being afterwards diluted. In this solution a strip of steel slowly and slightly became coated with copper by simple immersion. With one cell, the deposit was still slow, and the film non-adherent. Two cells were next tried, when deposition was somewhat quicker, but the plate only became coated in parts, with, however, a very bright film, more especially at its outer edges, where the metal was as bright as if it had been burnished. The anode kept perfectly clean in this solution.

30. *Ammonio-sulphate of Copper.*—This salt was prepared by the pharmaceutical method, equivalent proportions of copper sulphate and ammonia carbonate being triturated together in a mortar until carbonic acid ceased to be given off. A moderately-strong solution of the salt was then made, in which a steel plate received no metallic deposit by simple immersion, neither could any deposit be obtained with the current from a single Daniell. With two cells, however, a deposit of copper slowly formed upon a steel plate, which was very adherent. As in the case of the ammonio nitrate solution, a bright green deposit formed on the anode.

31. *Oxide of Copper in Ammonia.*—A quantity of hydrated oxide of copper was digested in strong liquid ammonia, and the solution afterwards moderately diluted with water. With the current from two cells, copper slowly deposited on a steel cathode, but this was only adherent in patches, the remaining portions of the film becoming readily detached by scouring with silver sand.

32. *Carbonate of Copper in Carbonate of Ammonia.*—Moist carbonate of copper was digested in a strong solution of sesquicarbonate of ammonia, and the resulting blue solution was first electrolysed in its concentrated condition with the current from a single Daniell, when a bright and fairly adherent deposit slowly formed on a steel plate. The solution was next diluted with about three volumes of water, when it was found that with the same current deposition proceeded somewhat quicker. With two cells and small anode surface, the copper deposited very quickly, the cathode being kept in motion for a few moments and then allowed to rest undisturbed for about 10 minutes. On scouring the plate with sand at this time, the coating was found to be more adherent than under the previous conditions. There was no deposit on steel by simple immersion in this solution, but a strip of zinc placed in the liquid slowly became coated with an adherent film of copper, the metal retaining its reguline condition even after the zinc plate had been immersed for a considerable time, there being no tendency for the metal to go down in a spongy state. With the current from a single cell a plate of zinc promptly received a coating of copper, which adhered firmly to that metal. During the electrolysis the anode kept perfectly clean.

33. *Carbonate of Copper in Bisulphate of Potassa.*—A bath was prepared from this combination by digesting recently-precipitated carbonate of copper in a strong solution of bisulphate of potassa (*sal enixum*), the resulting solution being of a pale blue colour. With the current from a single Daniell a very quick deposit of copper of good colour was obtained upon a steel plate, but this was only partially adherent. The solution was next diluted with a moderate proportion of water, when it was found that deposition still took place too promptly for an adhesive coating. It was therefore further diluted with increasing proportions of water, with a view to induce the copper to adhere to the steel. After many trials, however, this condition was only partially accomplished, and after the plate had been some time in the bath the deposit blackened at the lower corners and edges of the cathode, the film at such parts being more or less non-adherent. A strip of zinc immersed in this solution reduced the metal in the form of a dark non-adhesive powder. A solution was next prepared by dissolving hydrated oxide of copper in a strong solution of bisulphate of potassa, but this electrolyte, even when considerably diluted, failed to yield a perfectly adherent deposit of copper. On examining the anode, it was found to be coated with a yellow film of suboxide.

34. *Hyposulphite of Copper.*—Moist carbonate of copper was digested in a strong solution of hyposulphite of soda, the resulting liquid being colourless. The solution was first tried in its concentrated condition with the current from two cells, when a slight film of copper deposited upon a steel cathode, but in a short time this electrode became coated with a loose, dense, black deposit, and the liquid became discoloured. The solution was next diluted with water, when the copper deposited slowly, as before, but the metal adhered well to the steel plate. After about 20 minutes' immersion, however, the black deposit again formed. A strip of zinc immersed in the solution received a coating of copper, which at once alloyed itself with the zinc, forming a yellow coating of brass. The anode was found to be coated with an adherent layer of red suboxide of copper.

35. *Borate of Copper in Sulphate of Alumina.*—A solution was formed by digesting recently precipitated borate of copper in a strong solution of sulphate of alumina, and the resulting liquid, which was of a pale blue colour, was afterwards diluted with water. With the current from two cells, a film of copper quickly formed upon a steel plate, but after a short immersion the deposit assumed an iridescent appearance—more especially on the side facing the anode. The anode surface was then reduced, and a fresh plate immersed, which was kept briskly in motion for some time, under which conditions a bright film of copper was obtained, but when the cathode was allowed to remain stationary for a few minutes the coating assumed a nearly black colour, and was readily removed from the plate with very light scouring.

36. *Arsenite of Copper in Cyanide of Potassium.*—This solution was prepared by digesting arsenite of copper in a strong and warm solution of cyanide of potassium, and the liquid afterwards diluted with water. With the current from two cells, arsenic alone deposited upon a steel plate when it was allowed to remain stationary, but when kept in motion copper also was deposited, forming a doubtful alloy of a yellowish tinge, but this did not adhere to the plate.

37. *Oxide of Copper in Sulphate of Soda.*—Moist hydrated oxide of copper was added to a strong and warm solution of sulphate of soda, and the mixture well stirred until the oxide was dissolved, the solution being afterwards diluted with water. With the current from one cell, an adherent film of copper was received upon a steel plate, which, however, turned black at the corners after a short immersion. When the solution was further diluted, and only a small surface of anode exposed, the film at first appeared bright

Digitized by Google

and of good colour, but after a time it assumed a mottled appearance. A strip of zinc immersed in this solution became coated with a dense black non-adherent film.

38. *Copper Carbonate in Tartaric Acid.*—Recently precipitated carbonate of copper was digested in a hot solution of tartaric acid, the resulting liquid being colourless. A strip of steel immersed in this solution, when cold, slowly became coated with copper. With the current from one cell, a steel plate received a film of copper soon after immersion, the deposited metal being very bright and adherent. A strip of zinc immersed in the liquid for some minutes became coated with a film of a golden-yellow colour, from the deposited copper having alloyed itself with the zinc. This yellow film, however, was easily scraped off the plate with the finger-nail.

39. *Copper Carbonate in Citrate of Ammonia.*—Small quantities at a time of moist carbonate of copper were added to a cold solution of citrate of ammonia, and the resulting solution, which was of a deep blue colour, was electrolysed with the current from one cell, when a steel plate received a prompt and bright deposit of copper, which adhered to the plate with great tenacity. By simple immersion, there was a slight tendency for the copper to deposit on steel after a few minutes; but a strip of zinc readily became coated with a bright and very adherent film of copper.

40. *Oxichloride of Copper in Hydrochloric Acid.*—A small quantity of strong hydrochloric acid was neutralised with recently precipitated and moist oxichloride of copper, and the solution then diluted with a considerable quantity of water. The solution, which was of a pale bluish-green colour, was electrolysed with one cell, when a film of copper slowly formed upon a steel plate, but the metal was non-adherent. In this bath, steel became coated by simple immersion, but the film, as before, was not adherent.

41. *Sulphate of Copper and Potassa.*—This solution was formed by dissolving hydrated oxide of copper in a warm solution of bisulphate of potassa, the resulting solution being of a greenish-blue colour. The solution, when cold, was tried with one cell, when a plate of steel received a bright but not very adhesive coating of copper. The liquid was then diluted with a large bulk of water and a fresh plate immersed, which was kept briskly in motion, when a fairly adherent film was obtained; but on the plate being allowed to rest undisturbed for a few minutes, it was found that the coating assumed a deep black colour, the deposit being easily detached by rubbing with the finger. The solution was next further diluted, and a smaller anode surface immersed, but the deposit, though somewhat improved in character, eventually acquired a very bad colour and a mottled appearance, the film being readily removed by scouring with sand.

42. *Oxichloride of Copper in Bisulphate of Potassa.*—A bath was formed by digesting moist oxichloride of copper in a strong solution of bisulphate of potassa in the cold for some hours, when a blue solution was obtained, which was afterwards diluted and electrolysed with the current from a single Daniell, when a dark-coloured deposit slowly formed upon a steel surface, which, however, was tolerably adherent. When the cathode was allowed to remain stationary, the film soon became still darker in colour, and this was not much improved by further dilutions of the liquid.

(*To be continued.*)

THE TELEPHONE IN SWITZERLAND.

The returns published by the Swiss Confederation with reference to telephonic communication in Switzerland show that since the establishment of the first telephone, in 1880, 61 towns have been provided with it, and there are now 6,944 telephonic stations, of which no fewer than 1,500 are in Geneva and its suburbs. Most of the Swiss towns are now connected with one another, Geneva communicating not only with Lausanne and other places on the shores of the lake, but with Berne, Zurich, and St. Gall. The Confederation has taken over the telephones, which are attached to the Department of Posts and Telegraphs, and the annual cost of subscription is only £6. Notwithstanding this moderate charge, the receipts exceed the expenditure by about £8,000, and the Federal Council now contemplates reducing the rate of subscription to £5 for the first year, £4 for the second, and 80f. for the following years, with a trifling supplemental charge for those subscribers who use the instrument more than 500 times during the twelvemonth.

NOTES ON THE DESIGN OF ELECTRIC MOTORS.*

BY ALBION T. SNELL.

In discussing the design of electric motors, it will be necessary to, first of all, consider the relation between the dynamo and the motor. The dynamo may be defined as a machine which converts mechanical work into electrical energy. The motor, when supplied with electrical energy, gives out mechanical work. So far, one is the converse of the other, and the dynamo is said to be a *reversible* machine.

The extent to which this is true depends very largely on the size of the machine under consideration. This follows from the fact that no matter how bad the design of motor, how weak the field, or how small the magnets or armature, it is sure to *run*. But a badly designed dynamo—one with relatively weak field-magnets say—will often not excite at all. Or, again, the proportions of armature and field may be relatively correct, but the mass so little that the like result obtains. Why is this, if the dynamo be a reversible machine? It has been shown that the reactions in the dynamo armature are not the same as those in the motor. And it is now generally admitted that the effect of self-induction in the dynamo armature is to increase the lead, while in the motor it tends to diminish it. And Mr. Mordey has pointed out that in the generator the effects of self-induction in the armature windings are opposite to those of the Foucault currents in the core; but in the motor they tend to increase each other.

The writer has had these differences brought under his notice very forcibly in the course of his experience, having been connected directly or indirectly with the design of more than 400 machines, varying in output from 1 h.p. to 100 h.p., and from 20 watts to 70,000 watts.

The chief cause of this difference between dynamo and motor is to be found in the mutual effects of armature and field. Profs. Ayrton and Perry so far back as 1883 showed, both mathematically and practically, that in the motor the magnetism of the armature and that of the field *might* be added; in fact, the motor effort is proportional to the magnetic strength of both armature and field-magnets, while in the dynamo the field due to the armature, considered as an independent magnet, must necessarily subtract from that of the magnets. These main distinctions occur in the nature of things. Their magnitude at first seems to be considerable; but really the effect depends very largely on the actual dimensions and the relative proportions adopted.

An ideal dynamo has an armature with neither internal resistance nor magnetism *per se*. The field-magnets alone are the source of lines of force. This condition may be the more nearly attained as the size and weight of the machine be increased. All text-books tell us that the field-magnet should be as powerful as possible, and the armature relatively weak. The exponents of the "reversible theory," and its carollary, "the better the dynamo the better the motor," appear to have had more experience of large machines than small ones. And their *experimentum crucis* necessarily leads them to such views. When such authorities as Hopkinson and Silvanus Thompson, Kapp and Mordey, assert anything electrical, few venture to disagree. But I beg to submit that an extended experience with small and medium size machines would modify their views, especially if weight-efficiency be an object in the design.

Be this as it may, a motor weighing 70lb. can be made to give a b.h.p. with 70 per cent. efficiency of conversion; but the same machine run as a dynamo would require nearly 50 per cent. more speed to give an output of 746 watts, and even then the efficiency between output and belt-power would be nowhere near 70 per cent. If this be true, and I think it beyond dispute, the theory and corollary require some modification. The approximation to the same efficiency when used as a dynamo or motor becomes the more apparent as the size of the machine is increased; but even up to 50 h.p. I prefer to make certain structural differences in the design of dynamos and motors, particularly if they be series-wound. With shunt machines the difference seems to be less marked owing to the field being nearly constant. If I mistake not, both Hopkinson and Mordey have founded their opinions on observations made from large shunt machines.

Much more might be said on this branch of the subject, and numerous actual experiments might be given in support of my views, but this would digress too much from the object of this paper. With these introductory remarks on the character of motors and their relationship to dynamos, I will pass on to the general design of motors.

There are two broad lines on which motors can be designed. They depend entirely whether weight and overall dimensions enter into the problem. It is only necessary to admit that a powerful armature with many ampere-turns and a relatively weak field will give the same torque as a strong field and a weak armature. Granting this, we can design a motor to give a certain torque independently of the total weight to some very considerable extent. We shall be guided in the proportion of armature and field by the work expected of the motor, by the price allowed for production, by the intended cost of future

* Paper read before the City and Guilds of London Institute Old Students' Association, January 16, 1889.

maintenance, and by the desired life. These two methods of design depend on the point of starting. In the *first* we take an armature of given size, select a certain surface velocity, and build the field as small as possible to give the desired torque. In the *second*, a certain type of field iron being determined on, we select an armature of sufficient cross-section to give the required results. The first of these two methods is by far the more scientific, inasmuch as the dimensions of the most costly part of the motor can be made a minimum. The second method, however, will sometimes occur in practice, and it is well to note the possible results of this as well as those of the more general case.

When designing a motor to do particular work the following points should be considered:

(1). What is likely to be the average torque on the motor and driven shaft?

(2). Is the motor to run continuously or only for short periods at more or less frequent intervals?

(3). What variations of load may be expected?

(4). What will be the maximum torque on the motor shaft?

(1) and (4) will determine the characteristic of the motor and the particular part of the curve at which the average torque shall be arranged to fall.

(4) will determine the size of the shaft and strength of the bearings.

(1) gives us the ratio of the speeds between the motor and the driven shaft.

(2) and (3) determine the limiting safe rise of temperature,

While the winding must be designed to satisfy all the conditions as nearly as may be.

It is not possible within the limit of a short paper to thoroughly analyse the different points to be observed. The general method can alone be indicated, and experience must teach the engineering student the rest. I will roughly run through the several conditions of design, and give such hints as appear likely to be of use.

Richmond, United States. That the method is unsatisfactory and can be much improved on there is no doubt, for Mr. Sprague has already (October 2nd, 1888) published drawings of a new tramcar involving two motors with *countershafts.*

Engineers using electric motors seem to forget that a motor, although very efficient at or about a certain speed, is most inefficient at low speeds (*vide* Fig. 1).* Too much stress is laid on the property of a motor exerting a maximum torque at starting. It is forgotten that the efficiency is *nil* under the condition of maximum torque, and that it increases very slowly until the point of 50 per cent. is reached. There are other sides, of course, to the question; but I wish here to strongly emphasise the primary condition of motor design—viz., attention to the torque of motor and main shaft.

Having then determined the torques of the system, the ratio of our gearing is known. Let us suppose that the motor torque be $\frac{1}{10}$th that of the main shaft, and that the gearing be accordingly in the ratio of 1:10. We have now to select an armature that will give us this torque at the speed required, satisfying also the conditions of durability, and that the rise of temperature will not exceed a certain limit—say 60deg. F., above the temperature of the room.

The mathematical expression for the torque of a motor is simple.

Let T be the torque. The output required of the motor at n revolutions per minute is, say, 1 b.h.p.

Then $$T = \frac{B.H.P.}{2\pi n} = \frac{33,000}{2\pi n} = \frac{5,280}{n} \text{lb. ft.} \quad (a).$$

That is, the moment of the forces tending to turn the armature is equal to $\frac{5,280}{n}$lb. acting at a radius of 1ft.

To get the exact pull on the periphery, it will be necessary to multiply this quantity by the ratio $\frac{1}{r}$, where r = the mean radius of the armature in feet.

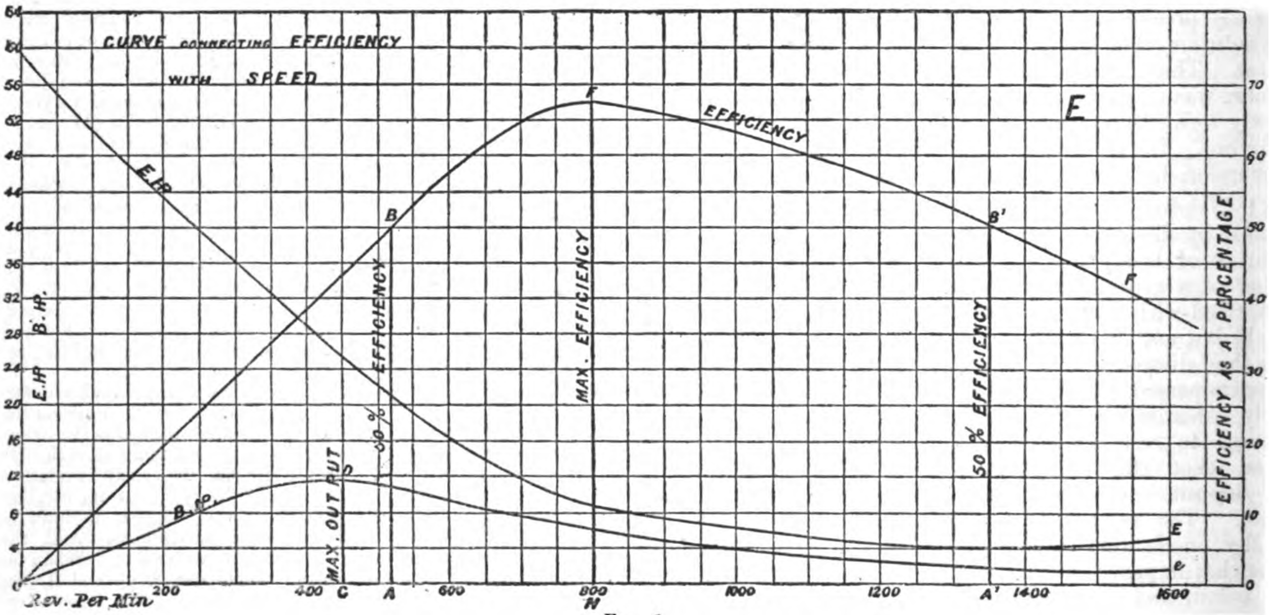

Fig. 1.

The first thing to be noted is the torque on the driven shaft. This is not always an easy thing to get at owing to the want of a little scientific nous in the ordinary mechanic. If, however, this be known, it is possible to determine within a few per cent. the required current, and the best ratio of gearing to get a maximum average efficiency from the motor. If this be accomplished, the motor will be a success. If the motor be designed on the assumption of so much horse-power being required, and gearing be accordingly selected, it probably will happen that, though the estimate of power be fairly correct, the motor will be unsuited to the work. The current, and consequently the torque on the motor-shaft, will probably be excessive. The efficiency of the motor will thus be low, and the e.h.p. absorbed excessive, while, further, the speed will be too slow. The obvious remedy would be an increase of the ratio of the intermediate gearing; but if the surface velocity of the motor be correctly designed the increased speed will be too great, and, consequently, introduce other difficulties; in fact, the motor will be a failure—not from any intrinsic fault, but simply because improperly designed for the work.

Daily one comes across machines driven by electricity, steam, air, or water, in which the same fault appears. The speed of the prime shaft is not properly proportioned to that of the main or driven shaft. The consequent loss in possible efficiency is oftentimes not known, or, if suspected, is ignored. This sort of thing did well enough years ago; but addressing a body of educated men who are likely to occupy leading positions among the engineers of the immediate future, I cannot pass it by without protest. I therefore beg to impress on you the necessity of determining in some way or other the actual number of foot pounds required to make one revolution of the main shaft. Your ingenuity will suggest many ways of doing this in most cases.

As an illustration of my point, I will mention the many attempts to run electric tramcars by direct gearing, *i.e.*, without a countershaft. Nearly every firm that has tried the tramcar problem has made the attempt. The last has been the Sprague motor line at

The tangential strain on the wire is therefore

$$= \frac{5280}{n} \cdot \frac{1}{r} \text{lb.} \quad (\beta)$$

This latter quantity is what we require in designing the motor. In order to obtain the desired couple on our armature, we make $T = \frac{Z_a N t C_a}{2\pi}$ (γ), where Z_a = the number of lines of force passing through the armature, $N t$ = the number of turns of wire counted all round, C_a = current flowing in any one coil of the armature—*i.e.*, half the total current—and r = mean radius of the armature core. It will be noted that the field does not come directly into the question. The function of the field-magnets is only to supply a magnetic field. It will be our care to so arrange the magnets and their windings that the proper value of Z_a is obtained. This is all that is necessary now. I shall have occasion to comment on this assumption later on when considering the field.

We have now to determine the values of Z_a, $N t$, and C_a.

C_a will usually be given us by the condition of supply and the horse-power required.

Z_a can be determined from the equation $Z_a = 2 a b z$ (δ), where z = lines per square inch, a = depth of core in inches, b = the length of armature *less the insulation* in inches.

Experience alone can tell us the best shape and size of armature core, but since the total cross-section ($= 2 a b$) is known no great difficulty presents itself. The depth of core will be mainly determined

* Curve E E is the value of the e.h.p. for the different speeds, the motor running at constant potential. O e is an approximation to the corresponding b.h.p.; and O F F is the commercial efficiency (plotted to another scale). It will be noted that the efficiency increases at first with the speed, and, after attaining a maximum, slowly decreases, having passed through two points of 50 per cent. efficiency.

by the style of winding and the value of T. For a small torque, a small armature and a large number of revolutions will be chosen ; for a large torque, a large, slow-speed armature is required. It will be necessary to note that a large cylinder or ring armature of short length is equivalent to a long drum of smaller diameter.

Then, assuming that the core be chosen, a, b, and r are known. It only remains to substitute these values in (γ) and solve for $N\,t$. If the quantities are properly chosen, $N\,t$ will have such a value that for a suitable current density the depth of winding will be about 10 per cent. of the core radius for cylinders and 15 per cent. for drums.

If the value of $N\,t$ be not a rational one, the dimensions of the core must be altered. A few trials will illustrate this important part of the design, but practice alone can give ease and certainty.

In actual practice the matter is much simplified by previous experience and by fixed sizes of cores. It is then customary to select a wire to suit the current given, and to vary the speed so as to make the magnetic density suitable for the work. This is the crucial part of the whole thing. In other words, the motor is designed to give the required torque at a certain part of the characteristic. This point varies with the shape of the curve and with the conditions of work expected. My meaning will be more easily seen when the field-magnets have been discussed.

The best relative dimensions of armature and field cores is an open question. This is apparent from what has already been said. It depends entirely on the object aimed at. If weight efficiency be the desideratum, the armature *must* be relatively powerful, and the cross-section of the cores may be made equal, allowing, of course, for the different permeabilities of the iron used. But if cheapness be the principal object, then a heavy field and a small armature are necessary. Speaking generally, the field strength has to be *relatively* greater as the size of the machine is increased.

The design of the motor field presents some considerable difficult to the student. There are so many shapes and forms in vogue, and the same end seems to be attained with such opposite forms. With few exceptions, too, even old-established firms are continually changing their patterns, often with no apparent effect other than a weakening of the public confidence, and a considerable needless expense. Indeed, the engineering draughtsman seems to be at his wit's end to bring out a new design. Yet there is really no ambiguity on the subject. Text-books tell us the best form of magnet is that, *cæteris paribus*, which offers the least magnetic resistance, with a maximum cross-section and a minimum perimeter. Theory then points to a horseshoe magnet, of circular form and round cross-section. Difficulties of construction, however, render this ideal form too costly, and the matter has to be compromised. It is to this endeavour to balance the advantages of theoretical indication with the necessities of engineering that we owe the numerous types of fields.

The design of the field is, however, not so important with the motor as with the dynamo, and a little consideration will enable the student to determine suitable proportions.

In the first place, the field has to supply a certain number of lines of force to the armature, or is expected to form poles of such strength that, in conjunction with those found in the armature, the necessary torque will be obtained. If gross weight be neglected, and a minimum expenditure of copper be desired, the single horseshoe is chosen. Such machines are common enough, and may be made vertical, horizontal, or inverted. The two first types are the better, since the leakage is less. If a light-weight machine be required, even at the expense of copper, then double horseshoe magnets are used. This type involves twice the number of ampere-turns to give the same strength of pole as the single magnet does ; but yet it has considerable advantages. The resultant magnetic field is likely to be more uniform, and less trouble is given by the brushes as a rule. If the armature be of a large diameter—say more than 24in.—it is better to have a four-pole machine, although the ampere-turns will be double that required with a double magnet, and four times that with a single one, if the same value of Z_a be taken. The Oerlikon dynamos, for the reduction of refractory ores, are made with six poles, and no doubt a more even distribution of magnetism is gained.

Having selected the form of magnet, the question of length and cross-section of limb arises. Here the criterion is simply sufficient space to wind the wire necessary to give the desired strength of poles and area enough to carry the magnetic flux required.

Here the student finds the first real difficulty. Let us review the position. We know the E.M.F. of supply or the allowed number of volts. The current is also approximately known from the b.h.p. and the assumed efficiency of conversion. The torque of the motor has been determined and expressed in terms of the magnetic flux through the armature iron, the effective cross-section, and the number of turns of wire. The dimensions and shape of the core are also agreed upon. So far it is a physical certainty. The problem now, primarily, is to design a field-magnet which, in conjunction with the armature, will give the required number of lines in the armature core. This is strictly all that is necessary. The question of economy of material and labour spent in the building of the field-magnets cannot be discussed here.

The magnetic flux in the magnets, to give a particular value of Z_a, I believe to be unattainable by direct calculation. Let Z_1 be the total lines induced at S in a single horseshoe magnet, and assume the lines to pass through the yoke Y and enter the armature at N (Fig. 2). The leakage which occurs all along the windings, and on the neutral part or yoke, reduces the value of Z_1 to, say Z_2. But Z_2 is still further lessened by leakage of lines from N to S outside of the iron or copper of the armature, and the effective number of lines is reduced to, say Z_3. Now, the ratio of $Z_1 : Z_2 : Z_3$ will vary according to the shape of iron, the length of cores, the contour of the winding, and the average density of magnetism. The problem is already sufficiently complex, but yet this is not all. We have yet to take into account the useful number of lines induced in the armature by its own windings = say, Z_4. This quantity is usually ignored in text-books, but I know from a large number of experiments, that if we wish to be accurate in our treatment of the subject, this factor must not be neglected. I cannot go into figures, but the

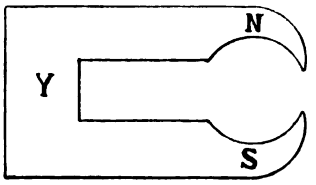

Fig. 2.

importance of the motor-armature, considered as an independent source of magnetism, may be understood from the following considerations :

Take a large series machine designed as a dynamo, having a relatively powerful field and weak armature. Let this be run at such a speed and output that the top of the straight part of the characteristic is just reached. Observe the speed, current, and terminal E.M.F. Then drive it as a motor, using the same number of volts on the terminals, and load the brake till the same value of the current is attained. The speed will usually, I think, be found to be nearly as great as that required as a dynamo.

Next take a smaller machine, designed as a motor—*i.e.*, one with a relatively weak field, etc.—and repeat the experiment. It will probably be found that for the same values of current and terminal E.M.F. the motor speed will be considerably *lower*.

This variation in the two speeds is due partly to the lead required in different machines when run as dynamos or motors, and also largely to the relative importance of the armature magnetism. Two simple equations will assist the study of the problem. Neglecting friction, let

E_d be the internal E M.F. of the dynamo.

$E_m = \dfrac{\text{B.H.P. } 746}{c}$ be the internal E.M.F. of the motor.

E_T be the terminal E.M.F. both of dynamo and motor.

C R be the volts lost over the internal resistance of the machine.

L_d be the value of the reactions of the dynamo armature.

L_m be the value of the reactions of the motor armature.

It will be necessary to note that L_d and L_m will vary with the lead required.

For the dynamo we have—

$$E_d = E_T + (C\,R + L_d) \quad . \quad . \quad . \quad . \quad . \quad \text{(I.)}$$

For the motor we have—

$$\frac{\text{B.H.P. } 746}{c} = E_m = E_T - (C\,R + L_m) \quad . \quad . \quad \text{(II.)}$$

Now, the speed of the motor varies as E_m, and the speed of the dynamo varies as E_d. It follows, then, that the motor speed should be *less* than the dynamo by a quantity proportional to $(C\,R + L_d) + (C\,R + L_m) = 2\,C\,R + L_d + L_m$. If the speed of the motor be *greater* than that given by these equations, L_m, the only quantity that can possibly be varied, must be a factor of importance and, moreover, of *negative sign*. This means that, in the motor, the armature adds magnetism to the resultant field, and thus increases the value of E_m, and, consequently, raises the speed. In the limit $L_m = C\,R$ and $E_T = E_m$—*see* (II.). Even if these values were possible in practice, E_m would be still less than E_d; so that the relative values of the speeds can only be seen by examination of the ratios $\frac{E_m}{n_m}$ and $\frac{E\,d}{n_d}$. It will be found with all normal machines that $\frac{E_m}{n_m}$ is less than $\frac{E\,d}{n_d}$. One must not confound the question of efficiency with these experiments. The efficiency of a dynamo for a given E.M.F. and current varies *inversely* as the speed, for the torque is clearly proportional to some function of the current, and is nearly independent of speed. The motor efficiency for the same electrical constants varies *directly* as the speed. In fact, we endeavour to make the dynamo speed a minimum, and the motor a maximum.

In the first experiment, say, in a large Edison-Hopkinson dynamo, the efficiency either as dynamo or motor will not differ much, but I should expect the motor to give the better result by a small percentage. The influence of the armature is relatively small, and the lead very little. The only objection to the machine, considered as a motor, is the weight, and, consequently, increased cost of material for a given output.

In the second experiment the armature is large compared with the field. Hence, the lead as a dynamo will be great—probably 30deg. at least in a positive direction ; as a motor, the lead, if any at all, will be much less, perhaps 5deg. in the negative direction. The machine will be inefficient as a dynamo, and require a high speed ; but as a motor it will be *much more* efficient, though the speed will not be so great as that required for the dynamo. The second machine will be a good motor—efficient light, and cheap.

This explanation is very rough, but it will help to explain the reason for considering the armature as an independent magnet in motor design. The Oerlikon plant, described in the technical press some six months ago, illustrates the point. The dynamo and motor have armatures identical both as regards the mass and distribution of iron and copper, but the motor field has 7 per cent. less copper and iron than the dynamo, and I know of many installations where proportionately much smaller motor fields are used with advantage.

Many attempts have been made to predetermine the characteristics

Digitized by Google

of dynamos and motors; yet the best seem to be but approximations. From what has already been said, it follows that the difficulty only lies with the number of lines of force in the field. This quantity is indeterminate, chiefly because we have no magnetic insulator. We can get the characteristic of the iron of both field and armature, and we know the resistance of the air space. But we do not know, and cannot as yet predetermine by calculation, the loss of magnetism which will take place over a new type of machine. Mr. Kapp has shown that this leakage is a function of linear dimensions of the machine, and hence varies with every type; indeed, no matter how small the alteration in design the value of the lost magnetism is changed. Practically this presents no difficulty, as only a few types obtain with most firms, and a few simple experiments will determine the number of ampere turns to give any desired result.

Dr. Hopkinson and Mr. Kapp were, perhaps, the first to move in this direction of calculating the ampere turns required in the field to give a definite magnetic flux in the armature. Both methods are well known, but a brief reference will assist us to follow the subject. Mr. Kapp started from a geometrical treatment of the design, and assumed the magnetic resistance of iron to be expressed by a law similar to that of Ohm, and the saturation effect was assumed to follow a tangent function. I have used the Kapp formulæ for many machines, both dynamos and motors; indeed, I think I was probably the first to apply them to motors; but the results are not satisfactory, particularly with large machines. The equations do not take into consideration the leakage in a sufficiently accurate manner, and the ampere-turns have to be increased from 25 per cent. to 100 per cent. above the value given by calculation. The characteristic thus obtained usually rises too slowly, and after cutting the real curve about the point of half-saturation of the field-magnet, does not fall sufficiently rapidly. My experience, I believe, is fairly well borne out by other users of the Kapp formulæ.

Hopkinson starts on a different basis. He determines experimentally the curves of saturation of both field and armature iron, and expresses the magnetic flux in terms of absolute magnetising force ($4\pi S i$) per centimetre length of core. The specific resistance of air is also determined by experiment. So far this is perfectly safe ground. But the characteristic of the machine itself is the summation of the curves of the field and armature iron and the air space, modified by the leakage and the reactions of the armature. Hopkinson has now to resort to experiment to find the magnitude of these disturbing influences, and a good deal of approximation or experimenting is required. Indeed, the method is not applicable to a new type of machine without considerable knowledge of the subject.

Prof. Silvanus Thompson, in the third edition of "Dynamo-Electric Machinery," gives a method combining both Hopkinson's curves and Frölich's equation:

$$N = N_1 \frac{S i}{S i + (S i)_1}.$$

N = maximum number of lines in the field-magnet.
N_1 = lines in field-magnets to give the diacritical value.
$S i$ = ampere-turns to give N.
$S i_1$ = ampere-turns to give N_1.

But this, again, demands an experimental determination of the leakage coefficient, and does not seem to me to advance the subject much.

Mr. Esson employs a modification of Dr. Hopkinson's method. Using the saturation curves of the iron and specific resistance of the air as his starting points, and selecting a definite value of Z_a, he determines the number of ampere-turns per centimetre of magnet core to give this value in the armature, neglecting leakage or self-induction. With a known type of machine this method presents great advantages, for the field-winding is given by simple reference to the curves.

Fortunately for us practical men, there is no pressing need of an exact mathematical solution. With a known type of field, machines of any output can be designed with certainty from previous experience and easy applications of the rule of three.

It may be noted that the slope of the characteristic is mainly determined by the resistance of the air gap. The curves of the field and armature iron do not largely affect the general shape till the diacritical points of either be reached. If the field be so crowded with wire that this point be passed, then the characteristic of the machine will bend rapidly.

Before leaving this part of the subject, I will briefly examine the question of pole-pieces.

Judging from the variety of shapes of polar extensions obtaining in machines in the market to-day, there seems to be no little ambiguity on the subject. Some makers use long poles, extending over nearly 160deg. of the armature periphery. Others cover 90deg. to 100deg. Some machines are to be found with long, thin, sharp extensions, whilst some have short, thick, and rounded ends. Each in its way accomplishes a particular end, but only want of knowledge could lead to the extreme proportions sometimes met with. This variety of dimensions in the pole-pieces and extensions arises from an attempted compromise between theory and simplicity of design.

Theory, on the one hand, points to an extended pole-piece if a low magnetic resistance of the air gap be desired. But since there is a tendency for the magnetic density to increase at the extremities of the poles, an undue lengthening of the arc encircled leads to a distortion of the main field. And, further, the position of commutation becomes a line, whilst really there should be some two or three segments on either side on which the brushes may rest without causing sparking or heating of the coils short-circuited beneath them.

Theoretical considerations, then, compel us to shorten the polar extensions, although we thereby raise the total magnetic resistance. This involves, however, no practical loss, for magnetism is cheap, and a few more ampere-turns will compensate for the weakened field.

It is curious to note how the tendency to shorten the pole-pieces has increased during the last 12 months or so. The Manchester dynamo used to have pole-pieces extending over 139deg. I heard the other day of a Manchester machine with poles not more than 90deg. in length. Messrs. Paterson and Cooper are also making both dynamos and motors with short poles; so are many other firms.

In some designs there are practical reasons for shortening the poles. If the cores are vertical, it is a convenience to be able to slip the windings over the poles. To attain this, the cores are prolonged and the poles bored out of them, instead of being built up of separate castings. This is applicable to both cast and wrought iron magnets.

Rounded polar extensions are also used in some designs, particularly with high-tension machines. I think this was first done in the Weston dynamos. Speaking generally, for motor pole-pieces I would recommend that the arc embraced be not more than 120deg., preferably rather less, and that the poles be rounded at all their extremities. The section of the poles should vary about in proportion to the magnetic flux desired. By a careful attention to this point the field may be properly spread over the whole of the coils beneath the poles, and the E.M.F. induced per coil be approximately the same. This is a matter of no little importance in large machines.

The best way of testing the activity of the different coils is the one first used by Mordey, I believe. By a simple arrangement of two movable brushes, the E.M.F. of coils in different parts of the field is successively measured and the result plotted. This gives the differential curve of potential. From this the integral curve may be obtained, or a direct experiment will give the same result. Fix one lead of the voltmeter to, say, the negative brush, and move the other in contact with the commutator through spaces equal to the angular width of one coil, taking readings at each space. These two curves show at a glance the relative activity of the coils and the distribution of the main field. No better method can be devised for showing the exact action of the armature, and the relative advantages of differently shaped poles and polar extensions are at once apparent.

This method is also very useful for showing the difference between the distribution of magnetism in the dynamo and motor field. I have derived considerable assistance from an exhaustive treatment of different machines in this manner. The results obtained are very curious, and serve to explain why it is advisable to make a difference between machines used as dynamos or as motors.

Generally motors are likely to have greater and more sudden variations of load than dynamos, hence the necessity for extra care in designing the pole-pieces. The principal point to be aimed at is to make the position of commutation sufficiently large for the variations likely to occur.

Assuming we have now designed and built our motor on the lines discussed here, it will be necessary to examine the degree of excellence attained. This is best done by brake tests. It will not be necessary to run the motor at a constant potential; indeed, in practice this is often a matter of no little difficulty. Let our motor be series-wound, and designed to run on a lighting circuit of 100 volts. Measure the ohmic resistance hot. Arrange the motor with a Prony or other absorption brake, and put a suitable resistance in series with the windings, so that any desired E.M.F. may be obtained within the limits of supply.

First, run the motor light—*i.e.*, without the brake, at the highest speed required of it, and note the terminal volts and the amperes. Then place the brake in position and screw down the blocks. Take readings with different loads, varying the current by intervals of one ampere, and noting the corresponding volts and speeds. When the maximum load is reached, we have all the data for calculating the performance of our motor. Arrange ten columns with following headings:

Speed.	Weight	Volts.	Amp.	B.H.P.	E.H.P.	Efficiency.	$\frac{E}{n}$	$\frac{e}{n}$	$\frac{\text{B.H.P. } 746}{n c}$

The first four are filled in from the observations of the test. The b.h.p. is calculated from the speed, the brake load, and the brake constant. The e.h.p. and the efficiency speak for themselves. We have now three columns left. From these we purpose to plot three curves that will show how far our method of design is successful.

The first, $\frac{E}{n}$, is the terminal E.M.F. divided by the speed obtaining for the particular value of E.

The second, $\frac{e}{n}$, is the so-called back E.M.F. ($= E - C R$) divided by the same value of n.

The third, $\frac{\text{B.H.P. } 746}{n c}$, is really of the same order—viz., a definite number of volts absorbed per revolution *in actual work on the brake.*

This requires some explanation. Note that the b.h.p. multiplied by 746 gives the available useful h.p. in watts, *i.e.*, a quantity that can be expressed by the symbol C E. We know the current flowing for any load, but do not know the exact fraction of the applied E.M.F. usefully employed for external work. But if we divide the b.h.p. expressed in watts by the known currents, the value of the unknown volts is given. This quantity is divided by n to reduce it to volts per revolution. The efficiency is thus given us by dividing $\frac{\text{B.H.P. } 746}{n c} / \frac{E}{n}$, or efficiency $= \frac{\text{B.H.P. } 746}{c E}$. We now take a piece of squared paper, and set off the current as abscissæ, and for ordinates the volts per revolution (Fig. 3). Then we plot against the several currents the correspondin

values of $\frac{E}{n}$, $\frac{e}{n}$, $\frac{B.H.P.\ 746}{n\,c}$. This gives us three curves. Two of these rise from the origin 0; but the third, the curve of useful work, starts at that particular value of c, which is just sufficient to overcome the static resistance of the motor. It will be noted that these curves tend to diverge from parallelism as the load increases. They show on inspection two things of great importance in motor design. The height of the ordinates between $\frac{E}{n}$ and $\frac{e}{n}$ show the E.M.F. lost over the ohmic resistance of the machine when heated to its normal temperature. The distance between $\frac{e}{n}$ and the lowest curve $\frac{B.H.P.\ 746}{n\,c}$ shows the E.M.F. lost from all other causes—viz., material and magnetic friction, and by induction. These three curves give at a glance the value of the motor as a converter of energy, and they show not only where the losses occur, but they give the magnitudes. The several quantities are divided by n, simply because it is practically difficult to make a test with constant speed. Since n is proportional to $\frac{B.H.P.\ 746}{nc}$, and is the same for the three ordinates corresponding to each value of c, no error of importance is introduced.

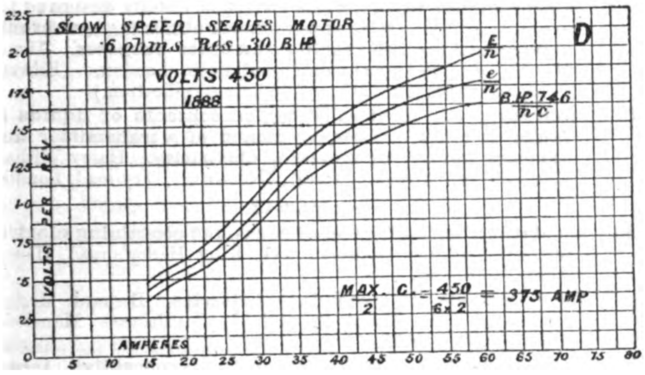

Fig. 3.

We now can see whether the losses, other than those due to the internal resistance, are excessive. The heat waste is a necessary evil, and can only be reduced within certain limits. The area between $\frac{e}{n}$ and the work curve can, however, be made very small. In a really well-designed motor this area should always be considerably less than that proportional to C^2 R.

If the losses due to friction and Foucault currents be larger than those caused by the copper resistance, the machine is badly designed. Our motor, however, will not only have a small value for C^2 R, but its other losses will not exceed $\frac{C^2 R}{2}$.

With these rough notes I close my paper. I may not have told you much that is new, but I hope to have made clear some of the more general difficulties, and to have put the design of motors on a simple engineering basis.

Discussion.

Mr. W. B. Esson: No one regrets more than I do the fact that Mr. Snell himself was not able to be present, but as I have talked over the paper with Mr. Snell, and he is fully aware of what I am going to say, he will probably be just as able to answer my remarks as if he were here. Taking the principle of reversibility, Mr. Snell finds that for a motor there is no critical current—that is, any current above that requires to overcome its friction will make it run. But for a dynamo a current lower than a certain value, called the critical current, is impossible. From this Mr. Snell seems to think that there is something radically wrong in the principle of reversibility, but I think this is a mistake. I made some experiments years ago to ascertain the effects of the reactions of the armature on the field, and concluded that in both dynamo and motor the effects were exactly similar. The case stands thus: Take a series machine and send a certain current through the field-magnets and armature. There is undoubtedly a delay in magnetisation, as pointed out by Ayrton and Perry some years ago, but I do not attach importance to this effect in continuous current machines. Although negligible in these, in alternate machines, however, the magnetic delay becomes enormously important. Well, neglecting this delay, let us send, in both motor and dynamo, the same current through the magnets and armature; it stands to reason that whichever way the armature turns the reaction must be exactly the same, provided that the back lead in the motor is equal to the forward lead in the dynamo. In a motor the only difference is that the armature runs round the other way, the magnetisation of the system and distribution of the field being the same in both cases. In the experiments mentioned, a dynamo was taken with a Gramme ring. This was run to produce several different currents. As a motor it was run at the same speed, and braked until the same currents flowed as were generated when it ran as a dynamo. With the current flowing in the same direction through the machine, the armature revolved, of course, in the opposite direction, the brushes having the tips rounded so that their ends did not turn up with the reversal. If V_1 and V_2 are the differences of potential at the terminals of the dynamo and motor, then I found in each case that—

$$V_1 + C\,R = V_2 - C\,R,$$

where C was the current and R the resistance of the machine. I concluded from this that the effect of self-induction might be neglected, and that the delay in the magnetisation of the armature core was also inappreciable.

Now we come to self-induction. In this direction I have been making several experiments lately, and find that in armature cores saturated to 18,000 C.G.S. the effect of self-induction may be entirely neglected. The experiments are made thus: The machine is separately excited, and run without any lead on open circuit, the E.M.F. and speed being noted, also the ampere-turns on the field. We now let a current flow through the machine and note the increase of excitement required to bring the E.M.F. to its previous value—that is to say, the difference of potential at the brushes is equal to its previous value *minus* the current into the resistance of the armature. There is no lead to the brushes, and therefore any weakening of the field is due to self-induction; and I find that at 18,000 C.G.S. the number of turns required to bring the potential when the current flows up to its former value is inappreciable, while at lower degrees of saturation a certain number of ampere-turns have to be added, which get larger as the saturation is reduced.

Regarding the effect of the armature lines on the field lines, I disagree entirely with Mr. Snell. It is quite true that Ayrton and Perry showed that the effects due to both might be added if the motor were worked with a forward lead, but if I recollect rightly, Ayrton and Perry stated that under usual conditions of work the brushes must have a negative lead. With this you must have a weakening of the field. You cannot have an increase—it is a physical impossibility. I might say that the very reason of a shunt motor governing so perfectly is due to this weakening effect on the field of the armature windings. As the current rises the field is weakened, and the effect is similar to that of a series coil wound on the magnets in the reverse direction to the shunt. For constant speed we require, therefore, no compound winding, but only a particular relation of field to armature. I have seen a motor in which the speed actually increased as the load was put on.

As to the ratio of field-magnet to armature cross-section, it is worthy of note that the cross-section of armature core can be varied very considerably without affecting to any considerable extent the number of lines of force through it. This arises from the fact that the ampere-turns required for the induction through the core is only a fraction of the total ampere-turns for the whole machine. In investigating this my firm constructed two armatures—one had a cross-section equal to ·6 that of the magnets; the other was ·8. The windings were similar, and so was the length; in fact, the only difference was that the hole in the centre of the armature was in one of them smaller. Although the increase in the cross-section was very considerable, the maximum increase in induction due to similar excitements was in the core of larger section only from 5 to 6 per cent. The gain is therefore so small for considerable increase in weight, that I think it is not worth while making two types.

For "useful" lines induced by the current in the armature core, Mr. Snell ought to substitute "useless," for, as I have already shown, the field is always weakened by them, not strengthened.

I may say that it is a very difficult thing to calculate the magnetic leakage before the machine is built, but it is very simple to measure the leakage afterwards, and from that it is tolerably easy to deduce the leakage in other machines, both of the same and modified types. One point is worthy of remark. Taking the single horseshoe magnet, suppose that in such a machine the ratio of the total lines of force induced in the magnet limbs to those passing through the armature core is 1·32. Now, imagine that you make a mistake in your calculation before the machine is made by assuming the ratio at 1·2, instead of 1·32. The error in the assumed leakage is 10 per cent., but the difference in the E.M.F. of the machine due to having made this error will only be about 2 per cent. The reason of this is that the number of ampere-turns required for the induction in the magnets themselves is fractional as compared with that required for the whole machine.

If the terminal difference of potential = V is the same in both dynamo and motor, their speeds will be in the ratio V + C R : V − C R, the dynamo, of course, being always the higher. I may mention that the efficiency of a motor is always greater than that of a dynamo at the same speed and current, the efficiencies standing in the ratio of $\frac{E}{E + C\,R}$: $\frac{E - C\,R}{E}$ where E is the E.M.F. generated in each case. Of course it makes no difference to the E.M.F. whether the armature is belt driven or current driven, provided the fields are in each case the same.

One of the chief reasons for the ampere-turns having to be increased over that shown by the calculation is, because in the calculation the demagnetising effect of the armature upon the field-magnets is neglected. This weakening effect is due to the lead of the brushes. In the Manchester machine, for instance, Dr. E. Hopkinson tells me that there are as many ampere-turns of series as of shunt wire, and the chief use of the series wire is to compensate the weakening effect produced by the current flowing through the armature.

Mr. Snell says, referring to the method I use, that I neglect leakage and self-induction. As a matter of fact, I neglect nothing, or rather I only neglect those things that are negligible. Self-induction is negligible, and the leakage I take always at one fixed ratio, an error in this producing, as I have shown, very small effect on the output of the machine.

In conclusion, I again express my regret at the absence of the author. Though my remarks have been of a somewhat critical character, it will be understood, I hope, that concerning all the points of which I have not spoken I have only to utter unqualified praise. They are only the points to which I in some degree take exception that I have called attention to.

NEW COMPANIES REGISTERED.

Newcastle-on-Tyne Electric Supply Company, Limited.—Registered by Pattison, Wigg and Co., 11, Queen Victoria-street, E.C., with a capital of £50,000 in £5 shares. The objects for which the Company is established are: To act as undertakers for the supply of electricity for lighting and any other purpose within the city of Newcastle-on-Tyne and elsewhere within the counties of Northumberland and Durham. The first subscribers are:

	Shares.
T. G. Gibson, solicitor, 42, Mosley-street, Newcastle-on-Tyne	1
F. R. Goddard, St. Nicholas Chambers, Newcastle-on-Tyne	1
A. W. Heaviside, 7, Grafton-road, Whitley, Newcastle-on-Tyne	1
M. L. Lambert, Whitley Hall, near Newcastle-on-Tyne	1
R. Lord, 75, Pilgrim-street, Newcastle-on-Tyne	1
F. T. Merz, The Quarries, Newcastle-on-Tyne	1
J. Price, 6, Osborne-villas, Newcastle-on-Tyne	1
R. S. Watson, 141, Pilgrim-street, Newcastle-on-Tyne	1

The number of Directors shall not be more than nine nor less than three, and the above signatories shall act as first Directors. The qualification of a Director shall be the holding in his own right of at least £100 in the capital of the Company, and the remuneration of Directors shall be determined in general meeting.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the week ended January 11 amounted to £5,247.

Globe Telegraph and Trust Company.—A dividend of 1s. 3d. per share is announced by the Board of the Globe Telegraph and Trust Company for the past quarter.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Telegraph Company, were £4,248.

Pilsen, Joel, and General Electric Light Company.—Mr. G. Shead, F.C.A., of 9, Laurence Pountney-hill, E.C., and Mr. W. H. Trentham, of 4, Stanhope-street, N.W., have been appointed joint liquidators of the Pilsen, Joel, and General Electric Light Company, Limited.

Change of Address.—In consequence of Victoria-street, Westminster, having been renumbered, the address of Messrs. Allpress and Belshaw will in future be 49, Victoria-street, instead of 3 and 4, St. Margaret's Offices, as heretofore.

Direct United States Cable Company, Limited.—This Company recommend an interim dividend of 3s. 6d. per share, tax free, being at the rate of 3½ per cent. per annum, for the quarter ending December 31, ayable on and after the 26th inst.

Eastern Extension, Australasia, and China Telegraph Company.—This Company notify that the interest, due on February 1 proximo, on their six per cent. debentures will be paid on and after that date at the Consolidated Bank, 52, Threadneedle-street, E.C. Coupons must be left three clear days for examination.

PROVISIONAL PATENTS, 1889.

JANUARY 7.

266. **A bracket to support the ear piece of telephones and other similar instruments.** Thomas Boothby, 65 and 66, Chancery-lane, London.

276. **Portable dynamo-electric signalling apparatus for military and other purposes.** Charles Grant, 5, Kelvinside-gardens, Glasgow.

278. **Lightning conductor for telegraphic purposes.** George Wehr, 166, Fleet-street, London. (Complete specification.)

282. **Improvements in conduits for electric mains.** Fletcher Coates, 65, Friday-street, E.C.

292. **Improvements in electric alarm thermometers.** Percy Frere Luck, 45, Southampton-buildings, London, W.C. (Complete specification.)

JANUARY 8.

306. **A new method of ornamenting metal articles by electro deposit process on the articles, and filling in the ornaments with japan, varnish, paint or enamel.** William Highfield Jones, William Hall Jones, and Benjamin Highfield Jones, Ablow-street, Wolverhampton.

319. **Improved apparatus and connections for charging and discharging storage batteries.** William Prescott Kookogey, 321, High Holborn, London. (Complete specification.)

320. **Improved methods of preparing solution compounds for galvanic batteries.** William Prescott Kookogey, 321, High Holborn, London. (Complete specification.)

342. **Improvements in or relating to the regulation of dynamo-electric machines.** William Morris Mordey, 46, Lincoln's-inn-fields, London, W.C.

361. **Improved methods of and apparatus for welding, forging, and otherwise working metals by the aid of electricity.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States. (Complete specification.)

362. **Improved methods of and apparatus for welding, shaping, and otherwise working metals by the aid of electricity.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.) (Complete specification.)

375. **Improvements in electric glow lamps.** Alexander Bernstein, 4, South-street, Finsbury, London. (Complete specification.)

377. **Improvements relating to the rivetting of metal plates and other objects by the aid of electricity.** Henry Harris Lake, 45, Southampton-buildings, London, W.C. (Elihu Thomson, United States.) (Complete specification.)

JANUARY 9.

385. **Improvements in electrical apparatus for preventing collisions between railway trains.** John Alexander Wilson and Frank Marshall Young, 41, Reform-street, Dundee.

435. **Improvements in dynamo-electric machines.** John Henry Holmes, Portland-road, Newcastle-on-Tyne, Northumberland.

JANUARY 10.

485. **Improvements in electric generators.** Henry Edward Newton, 6, Bream's-buildings, Chancery-lane, Middlesex. (Dionisio Piedrahita, France.)

JANUARY 11.

506. **Improvements in electrical switches, chiefly designed for use in connection with apparatus for obtaining synchronic movements for telegraphic and other purposes.** Henry Harris Lake, 45, Southampton-buildings, London. (Edward Fitzgerald Law, Turkey.) (Complete specification.)

549. **Indicating the level of water, or contents of liquids in tanks or other vessels, by means of a transmitter and recorder worked by means of electricity.** Harry William Charles Cox, 11, Galwey-street, Bath-street, City-road, London.

JANUARY 12.

586. **Insulating blocks for use with casings containing electric wires.** Frederick Bathurst, 111, King Henry's-road, Hampstead, Middlesex.

588. **Improvements in secondary batteries.** Bernard Mervyn Drake and John Marshall Gorham, 2, Prince's Mansions, Victoria-street, S.W.

590. **Improvements in liquid lamps for regenerative, incandescent, or ordinary lighting, heating, and general purposes.** John Henry Williams Stringfellow, 57, New Broad-street, City.

608. **Firing fog or other signals upon, or in connection with, a railway or tramway, either electrically or mechanically, the same being under control of authorised person.** Wm. Armstrong and Alfred Falconer Ball, 14, Lansdowne-terrace, Gosforth, Newcastle-on-Tyne.

613. **A combined holder for lamp and fuse with switch.** Walter Northcott Naylor and Walter James Naylor, 21, Finsbury-pavement, London.

614. **An improved form of electrical locking switch.** Walter Northcott Naylor and Walter James Naylor, 21, Finsbury-pavement.

SPECIFICATIONS PUBLISHED.

1887.

17,209. **Combined switch electric lamp support for conveyances.** Willing and Douglass. 8d.

1888.

1091. **Electrically-released counting mechanism.** Aird. 8d.
1254. **Electric lamps.** Spink and Gauzentes. 8d.
1798. **Telephonic transmitters.** Laurie. 8d.
1919. **Arc electric lamps.** Howes. 8d.
2073. **Electric alarm apparatus.** Iwanowski. 8d.
2251. **Electric circuit switches.** Graham. 8d.
2368. **Secondary batteries.** Bailey and Warner. 8d.
2438. **Incandescent electric lamps.** Langhans. 6d.
2450. **Electrical measuring instruments.** Hibbert. 8d.
8950. **Electrical traction.** Burdon. 6d.
10,604. **Secondary batteries.** Timmis. 6d.
11,082. **Transmitting and recording electrically autographic messages, &c.** Newton. (Gray.) 1s. 3d.
16,099. **Electrical switches.** Dorman and Smith. 8d.

NOTES.

Tramways in India.—Extensive tramways schemes are contemplated in Madras, and electricity will probably be used.

Windsor.—We understand that Messrs. Crompton and Co. have the order to supply a Crompton dynamo and a set of Crompton-Howell accumulators for Windsor Castle.

Society of Arts.—The date for the paper by Prof. Silvanus P. Thompson, at the Society of Arts, is fixed for Wednesday, March 6: subject, "Arc Lamps and their Mechanism."

Toulon.—The French Minister of the Marine has decided to fit the port of Toulon with electric light, to allow, in case of mobilisation, the troops and arms to be disembarked at night.

Seel Lamps.—The Seel Lamp Company are apparently making considerable strides on the Continent. They have lately sold their Belgian and Austrian patents, and works are being built in Brussels and Buda-Pesth.

Hyde Park Gate.—Consent has been given to the Kensington Court Electric Lighting Company to light the lamps at Hyde Park Gate, on condition that they hold the Vestry harmless against any loss or expense.

Underground Mains.—The St. James' Company have received permission to lay mains in Duke-street, St. James's, and other places, and the London Electric to lay mains through the Victoria Embankment Gardens, Charing Cross.

Electrical Road-Sweeper.—A project is afloat, we hear, to run an electric road-sweeper for London streets. This will be driven by accumulators, which also drive the revolving brush. No horses will be required, and one man will be enough to drive it.

Maxim Patent.—While financiers are trying to resuscitate the Maxim-Weston Company and sell patent rights, it would be as well to ask the question whether during the altercations the Maxim patents have not been allowed to lapse? If so, the company will not have much to sell.

Discussion on Electric Motors.—The adjourned discussion on Mr. Albion T. Snell's paper on "The Design of Electric Motors" will be continued at the Central Institution, South Kensington, on Wednesday next, at 7.45 p.m., when Prof. Ayrton is expected to make some remarks, and Mr. Snell to reply.

Birmingham Tramways.—It is definitely settled that the Bristol-road route of the Birmingham tramways, which was to have a cable system, is to be run by electricity, and application has been made to the Public Works Committee of the Birmingham Town Council for permission to use electricity as a motor along this route.

Ganz and Company.—The new alternating motor by Ganz and Co., of Buda-Pesth, entirely surpassing the Tesla motor by requiring only one circuit, is expected to do great things in the development of the motor industry. The same enterprising Austrian firm have just brought out a new and solid type of dynamo, built on excellent mechanical and electrical principles, which they called the Delta dynamo.

Gottenburg.—It may be remembered that Gottenburg is to be electrically lighted by a local company. The permanent plant will commence with sufficient power to provide current for 2,000 lamps, but before Christmas a trial run with a temporary 500 light plant was successfully made, and since then the accumulators have been installed and a trial made. The plant is by Messrs. Crompton and Co., and is giving complete satisfaction.

Chelsea.—The Vestry, on the recommendation of the Electric Lighting Committee, dissent from the granting of a proposed provisional order in the case of the London Electric Supply Corporation, Limited. Memorialists are also informed that the jurisdiction of the Vestry in the matter of overhead wires is limited in extent, difficult of application, and doubtful in its effects, and that the Vestry are not prepared at present to initiate litigation against the owners of the overhead wires.

Shoreditch.—The Shoreditch Vestry are recommended by their Parliamentary Committee—chiefly for the reason that overhead wires would be a source of great danger, and they were of opinion that no legislative sanction should be given to any scheme which included such a system—that the Board of Trade be memorialised not to consent to the present application by the London Electric Supply Corporation for a provisional order to lay down mains for the public and private lighting of the parish.

City Lighting.—At the meeting of the Commissioners of Sewers on Tuesday, which is the last of the present Commission, the Streets Committee brought up a report recommending that tenders for the electric lighting of the City, which was divided into three parts for the purpose, should be at once invited. The matter is left for the new Commission to carry out. It was also resolved that the court should formally oppose the various applications for electric lighting provisional orders so as to obtain a *locus standi* before Parliament.

Proposed Electric Tramway.—The tramway world is beginning to awaken to the advantages of electric traction for their work, which we have so persistently dinned into their ears, and various schemes are afloat for the introduction at once of the new system. One of these is for Morecambe, and, as will be seen from the advertisement, the Morecambe Tramways Company now invite tenders for the equipment and working of their line by electricity. This is the first invitation for a public tender for an electric tramway in this country.

Paris Exhibition.—Some of the large Davey-Paxman engines for the Paris Exhibition are now on the ground. Behind these engines and within the English machinery section will be a large installation by Crompton and Co., who will provide the electric lighting in the whole of the English and American and a large part of the French section of the Machinery Gallery. The French Government intend to supply the steam-power gratis to those exhibitors who require it, and to do this they will themselves purchase it of the exhibitors who produce it.

Newington.—At the Newington Vestry, on Wednesday, upon the recommendation of the Works and Sanitary Committee, it was resolved that the application of the House-to-House Electric Light Supply Company, Limited, for the consent of the Vestry to enable the company to apply to the Board of Trade for a license be not entertained; but they recommended that no objection be offered to the draft provisional order lodged by the London Electric Supply Corporation, or any action taken to watch the progress of the order through Parliament.

West Brompton Station.—The central station of the House-to-House Electric Light Company, at West

Digitized by Google

Brompton, was formerly opened for inspection yesterday. We have already given particulars of this station and a sketch plan of the arrangements on December 14th last year, and we shall give further details and illustrations of this most interesting station, which has its own special design of machinery, dynamos, meters, regulators, and switches from beginning to end. The station will be ready to light up in about three weeks, the first instalment being for about 12,000 lamps.

Berlin.—The central station at the Markgrafenstrasse, Berlin, has been increased to the extent of 1,200 h.p., and is connected with the station at the Mauerstrasse, which supplies the arc lamps to Unter den Linden, both stations having now a total of 3,900 h.p., capable of supplying current for equal to 40,000 incandescent lamps. Two further stations will be opened in the spring in the Spandauerstrasse and the Dorotheenstrasse, with 2,000 h.p. each, and that at the Mauerstrasse will also be increased by a similar amount, so that within three years the Berlin Electricitätswerke will have installed a total of about 14,000 h.p., equal to 150,000 incandescent lamps, or its current equivalent.

Burglar Alarms.—The recent homicidal burglary at Muswell Hill has aroused great indignation and even terror amongst suburban residents. The time would no doubt be ripe for a large disposal of electric burglar alarms, and supply electricians might reap a small harvest from this cause. Amateurs are becoming busy with their electric arrangements, and the *Standard* has a letter from "Paterfamilias," describing a simple alarm which he has fitted consisting of an old box-lid fitted with two brass screws as contacts, and hinged at or laid under a fur mat at the windows for the burglar to tread upon, which rings a loud bell in the hall. An advertisement in the society papers should bring a good crop of orders just now.

Overhead Wires.—At the Paddington Vestry on Tuesday, Mr. Mills moved: "That it be referred to the surveyor to prepare and furnish the Vestry with a return showing (*a*) a list of the streets and thoroughfares in the parish that are crossed by overhead wires; (*b*) the number of separate crossings of wires in each street; (*c*) the names and addresses of the persons or companies owning such wires; (*d*) the cases in which the erection of the wires has been sanctioned by the Vestry (for the purpose of determining whether in any, and, if in any, in what instances, rights of user have been acquired); (*e*) the dates respectively when the wires were erected." He contended that the wires were a great eyesore, and were here likely to be a source of considerable danger to the public. The motion was carried unanimously.

New York Subways.—The Board of Electrical Control of New York reports to Governor Hill that 240,155 lineal feet have been excavated for laying subways, and that 2,287,880ft. of single duct for telephone and telegraph service have been constructed in this city. The total capacity for wires is about 34,665 miles for telephone and telegraph, and 600 miles for electric light and power wires. They say that 4,453 miles of electrical conductors have been placed in the subways. The report complains of the escaping steam from the pipes of the Steam Heating Company. It also says that from 30 to 50 per cent. of existing poles and wires are "dead," and exist in violation of the rules of the Board, which have not been enforced by the proper authorities. The report says nothing of the degree of perfection of the subways as built.

Elwell-Parker.—The new and extensive works of Elwell-Parker, Limited, which we alluded to some time ago, are to be erected at Bushbury, just outside Wolverhampton, and adjacent to the main line of the London and North-Western Railway. The growth of the business of this company has been phenomenal, and reminds one of the rise of business firms in the first days of railway engineering: we recollect calling at the works when two or three sheds and 50 men were the extent of the premises. The present works are to cover some 12 acres, and will be occupied in manufacturing every kind of heavy electrical plant. Continuous and alternating lighting plants and depositing dynamos are now largely made, but the greatest development will probably be in tramway and motor work generally, for which the company are, we believe, specially laying themselves out. Besides the contract for the Birmingham tramways, they hold some valuable contracts for lighting, among which is one from Melbourne to the value of £20,000.

Swansea.—A scheme is proposed by the harbour trustees at Swansea, which is likely to encourage the thorough adoption of electric light in that town. The Corporation of Swansea, as already announced, are taking steps to obtain a provisional order. The preliminary steps were taken some three months ago, but it is not likely that the required sanction can be obtained for at least another three months, especially as the gas company may be expected to very strenuously oppose the innovation. This being so, it is encouraging to learn that the lighting by arc lamps at the East Dock has been so successful that the harbour trustees are intending to adopt the complete lighting of the whole dock estate by electricity, and it is suggested that the trustees will also agree to light Wind-street and other main streets adjacent to the docks with their surplus power. By this means, when the provisional order is under consideration, the town will have the advantage of experience of the light which has already proved itself satisfactory to the harbour trustees.

Edison Consolidation.—The announcement is made that the various Edison electrical manufacturing companies are to be consolidated into one Edison General Electric Company. The capital of the new company is close on £2,500,000. The incorporators are E. H. Johnson, the president of the Edison Electric Light Company; Samuel Insull, the manager of the Edison Machine Works; F. R. Upton, the vice-president of the Edison Lamp Company; C. Batchelor, of the Edison Laboratory, and A. O. Tate, Mr. Edison's secretary. The company thus formed takes over the Edison Machine Works, the Edison Lamp Company, and the big factory of Bergmann and Co., where details of the Edison system have been made; and it is understood that new factory facilities are to be provided at West Orange, N.J. Mr. Henry Villard and the well-known Deutsche Bank of Berlin are understood to be interested financially. It is said that the technical affiliations will include some of the leading firms in Europe—that of Siemens and Halske being one named.

Lamp-posts for Bath.—A Taunton firm, Messrs. C Allen and Son, Tone Engineering Works, has secured the contract for lamp-posts for the electric lights at Bath. The tenders are as follows: For about 340 iron electric light posts, 30ft. above ground, with roots varying in depth 3ft., 4ft., 5ft., and 6ft. respectively, with independent flanges projecting 2ft., to be fixed with wrought

Digitized by Google

wedges, delivered free in Bath, on Midland and Great Western rail, or water, for Mr. H. G. Massingham, Bath ; Allen and Son, Taunton, £6. 10s. (accepted); G. Smith and Co., Glasgow, £7. 7s. 6d.; Buller, Jobson and Co., Dudley, £7. 10s.; M. and W. Graybrook, Dudley, £8 ; Easton and Waldegrave, Taunton, £8. 2s. 6d.; Jukes, Coulson, Stokes, and Co., London, £8. 2s. 6d.; Statter and Co., West Drayton, £12. 7s. The firms tendering supplied their own designs. Messrs. Allen's posts, while being the cheapest, have ornamental brackets to support the lamps, and are fitted with an ingenious arrangement by which the lamps can be easily lowered, doing away with the necessity for carrying ladders for fixing and cleaning the lamps.

The Electric Motor in Mining.—A very interesting application of the electric motor to mining operations is that of a 5 h.p. Sprague motor at the works on the Big Bend River in California, where efforts were made last year to get at the river bottom and to extract the gold there supposed to have been deposited through the long centuries by the auriferous waters on their way downward from the mountains. The motor is at the end of an eight mile circuit, and the efficiency obtained at the point in question is 65 per cent. The work done was that of pumping out a shoal of water 600ft. square and 10ft. deep on the average. The whole shoal was unwatered in four days of 24 hours each, by two of the Sprague 5 h.p. motors. The pumps were in charge of a miner 60 years old, who two days before the installation was made did not know what a motor was. In his hands everything went well, however, and the service was perfect. In fact, no energy but electric could have been used in the place, the river running at the foot of precipitous mountains through deep gorges and narrow clefts in the rock. The potential used on the circuit was 600 volts.

Electrolytic Method of Liquefying Gases.—In the *Journal* of the Chemical Society an abstract is given of a paper by Mr. H. N. Warren : Strong hydrochloric acid is introduced into a combustion tube, bent at right angles, so as to cover two small platinum plates fused into the closed end of the tube; a plug of asbestos, saturated with concentrated sulphuric acid, is placed at the bend, the open and shorter arm is then fused up and immersed in a freezing mixture. On the passage of a current through the plates, gas is evolved and liquefies at the other end, but on removing the tube from the freezing mixture and discontinuing the current, the liquefied hydrogen chloride is reabsorbed by the water. The experiment may then be repeated. Other compound gases behave in a similar manner. When acidified water is decomposed in this apparatus, and a platinum plate covered with platinum-black has been fused in the short end, explosions occur there at intervals, and small quantities of water form, containing hydrogen peroxide, and having an ozonised odour. With chromic acid and water, the blue oxide of chromium is obtained. The method has also been applied to the liquefaction of oxygen and hydrogen, and the latter is said to have been "decidedly liquefied."

Overhead Telephone Rights.—The Corporation of Dorchester have attempted to take a new position with regard to the running of telephone wires overhead. Claiming the absolute ownership of the streets and roads, they have objected to the Western Counties and South Wales Telephone Company carrying their wires over such streets unless under their license, and with an undertaking to remove them after due notice. The Court of Appeal have long decided that wires may be carried over public roads at sufficient height without consent of the Highway Boards or local authorities. The Telephone Company cannot see their way how to admit the authority of the Corporation except, of course, over such property as is owned by the Corporation in the usual way, and have suggested that they either accept a license from the Corporation in respect of any property over which the Corporation are entitled to make such a condition, leaving its limits to be defined in event of any dispute (which would probably never arise), or to settle the question at once in any expeditious and inexpensive way by appeal to opinion of the court or a judge. Failing these arrangements, the Telephone Company, not having many subscribers in Dorchester, would be inclined to withdraw from the town and omit it from their system.

Gas Mains as Electrical Conduits.—The problem of conveying telephone and electric lighting wires underground in large cities has received a partial solution in New York, where for the last few years a telephone conductor has been run inside a gas main, between the gas works of the Consolidated Gas Company at 99th and 111th streets. The conductor enters the gaspipe by a stuffing-box, made gas-tight by plaster of paris. The wire is carried by glass insulators fixed in the roof of the pipe. The length of the circuit is over half a mile, and it has been in continual use. Owing to the success of this experiment, a series of new mains have recently been supplied with telephone cables, serving for the use of the gas company. The experiment tends to show that the mains of a gas company might even be employed for running the wires of an electric lighting company undergroυrd. It has been objected that a short-circuit in electric light circuits must cause explosions and tear up the whole city, but it is evident that a mixture of air and gas would be necessary for an explosion, for a gas jet on an open pipe does not produce the same effect. A deposit of carbon would be the only result in this case, which would increase while the leak continued. At any rate, there may be usefulness in the adoption of telephone wires for the gas companies themselves.

Electromotive Force of Selenium.—In the *Journal* of the Chemical Society the following abstract is given of a paper by S. Kalischer (*Ann. Phys. Chem.* [2], 35, 397—399). The author points out that the method described in von Uljanin's paper (Abstr., 1888, 883) of preparing selenium sensitive to the production of E.M.F. by the action of light had been described by him two years ago (Abstr., 1887, 693). He states that in the paper by Fritts, quoted by von Uljanin as well as by himself, there is no question of an E.M.F. caused by the exposure of selenium to light, as he had already pointed out. Righi, in a recent paper, states that he has obtained a current from a selenium cell in the dark, and suggests that the reason that other observers have not noticed this is that they have attributed the whole E.M.F. to the action of light. Kalischer states that he had tried to obtain an effect of this kind, but without result, and he says that it does not appear from Righi's description that daylight was totally excluded in his experiments. He points out, moreover, that the method of observation of the effect of light would preclude any interference from such an effect if it existed, and that the E.M.F.'s observed are therefore entirely due to light, and not the resultants of these and of effects of the kind which Righi states that he has obtained.

Electrical Exhibition at Birmingham.—We gave particulars in our issue of January 11 of a proposed Electrical and Industrial Exhibition, to be held in Bingley Hall, Birmingham, during the months of August, September, and October this year. The preliminary organisation is now complete, offices have been taken, and the regulations issued. The list of patrons comprises a large number of well-known names, including Lord Salisbury, Earl Compton, Mr. John Bright, Mr. Chamberlain, and many public men of Birmingham and the district, together with a formidable list of scientific men, headed by Sir William Thomson, with Mr. W. H. Preece, F.R.S., Profs. Hughes, Adams, Fleming, Perry, Forbes, and others. The exhibition will be, to a very large extent, electrical, as, indeed, all industrial work will rapidly tend to become, and will present a splendid opportunity of bringing forward the immense possibilities of the commercial application of the present developments of electrical industry in the centre of manufacturing England. A general prospectus of the proposed exhibits was given in the number mentioned above, and the main conditions are as follows: The forms of application for space must be filled up and delivered before 15th April. A charge for space of from 1s. 6d. to 2s. 6d. per square foot will be made, a remittance of 25 per cent. of the amount to accompany the form of application. Power will be supplied where necessary at the cost of the exhibitor. No exhibits will be received before 15th July, and must be delivered before the 22nd July. Applications will receive attention in priority of reception, and as the space for exhibitors in each section is limited an early application is advisable. Applicants for space from foreign countries and the colonies must appoint representatives in England to act on their behalf. Applications for space should be addressed to T. C. Sharp, manager, County-chambers, Corporation-street, Birmingham; telegraphic address, "Exhibit," Birmingham.

Electrolytic Inner Cells.—The *Electrical World* describes a new form of battery made by Messrs. Roberts and Brevoort, of New York, in which the difficulty experienced with porous cells with the diffusion of acids on the one hand if too porous, and high internal resistance on the other if but slightly porous, is overcome. In what may be an important improvement in batteries, these inventors have made the partition separating the two liquids in a battery of a material which should practically be non-porous, but with electrolytic properties, so that whether the battery be on an open circuit or closed, the liquid, as such, on one side of the partition would not interfere or intermingle with the liquid on the other side of the partition, or only to a very limited extent; but when the circuit is closed, and the battery is called upon to give a current of electricity, chemical action could take place through the partition. This property in a partition has been secured by the use of a number of materials. Among those first tried were gelatinous or jelly-like materials, such as boiled starch, which was confined between walls of cloth, so as to make a suitable diaphragm, and other vegetable and animal substances of a similar nature have been used. In the most recent form the inventors employ mineral substances of a gelatinous nature, and among others they tried the gelatinous silicate of soda, with which they impregnate the ordinary porous cup. The action of this diaphragm or partition the inventors explain as follows: The diaphragm or partition is a non-porous substantially-solid homogeneous wall, whose particles, while sufficiently solid and compact to maintain their compositions, and so prevent, for practical purposes, any transmission of fluid through them, are yet themselves able to act as electrolytes, and suffer such decompositions and re-combinations as are essential to the electrolytic transmissions of electric force. In other words, they have in the partition combined in the one substance the solid properties of the earthenware and the electrolytic properties of the liquid, or, as they say, they have made the electrolytes solid, and the partition electrolytic. The results obtained by the use of this non-porous partition are reported to be highly satisfactory, so that very nearly the entire theoretical amount of energy contained in the zinc is obtained as current in the external circuit, due to the absence of local action, even when the cell remains idle for long periods of time.

Central Station for Manchester.—A proposal to establish a station for Manchester, somewhere within half a mile of the Manchester Royal Infirmary, for a maximum of 10,000 lights, was brought forward at a special meeting of shareholders of the Manchester Edison-Swan Company on Tuesday last. Such a station would cost, including the laying of mains down the chief streets in the centre of Manchester, a sum of £40,000, with £8,000 a year for maintenance. If the whole of the lights were let at an average of 25s. per light, this would produce £12,500 per annum, or something above 10 per cent. on the original cost of the station. It was proposed that the charge per light should be graduated according to the number used. The estimate stated was regarded by the directors as a thoroughly reasonable one. Various proposals, fair even to the point of seeming to be generous, had been made unofficially to the Manchester Corporation, one of the proposals being that the company should not make more than 10 per cent. out of this new portion of their business, and that at the termination of any specified period the Corporation should have the privilege of buying up the undertaking for the benefit of the ratepayers. What was earned over 10 per cent. the consumers would receive the benefit of. The following resolutions were moved: "That this extraordinary general meeting of shareholders of the Manchester Edison-Swan Company, Limited, approves of the proposed scheme for the establishment of a central electric lighting station in Manchester, and authorises the directors to raise the required capital by making a call or calls, not exceeding in the aggregate £2 per share, as and when they may be required. The meeting expresses its earnest hope that the Corporation of Manchester may be induced to give the necessary facilities to enable the directors to carry the scheme into effect." "That a copy of the foregoing resolution be sent to the Mayor of Manchester and to every member of the Corporation." It was objected that the scheme was too philanthropic; that the shareholders would have to find the money, and in event of success would be limited to 10 per cent., the consumers getting the further benefit, whereas if loss were sustained the shareholders alone would suffer; and that the scheme was too speculative for the company to undertake. After further discussion, the motions were agreed to on the understanding that a canvass should be made to see how many people were willing to use the electric light and the Corporation approached on the subject, but that no money should be spent till the shareholders had had another opportunity of expressing their opinion about the proposal.

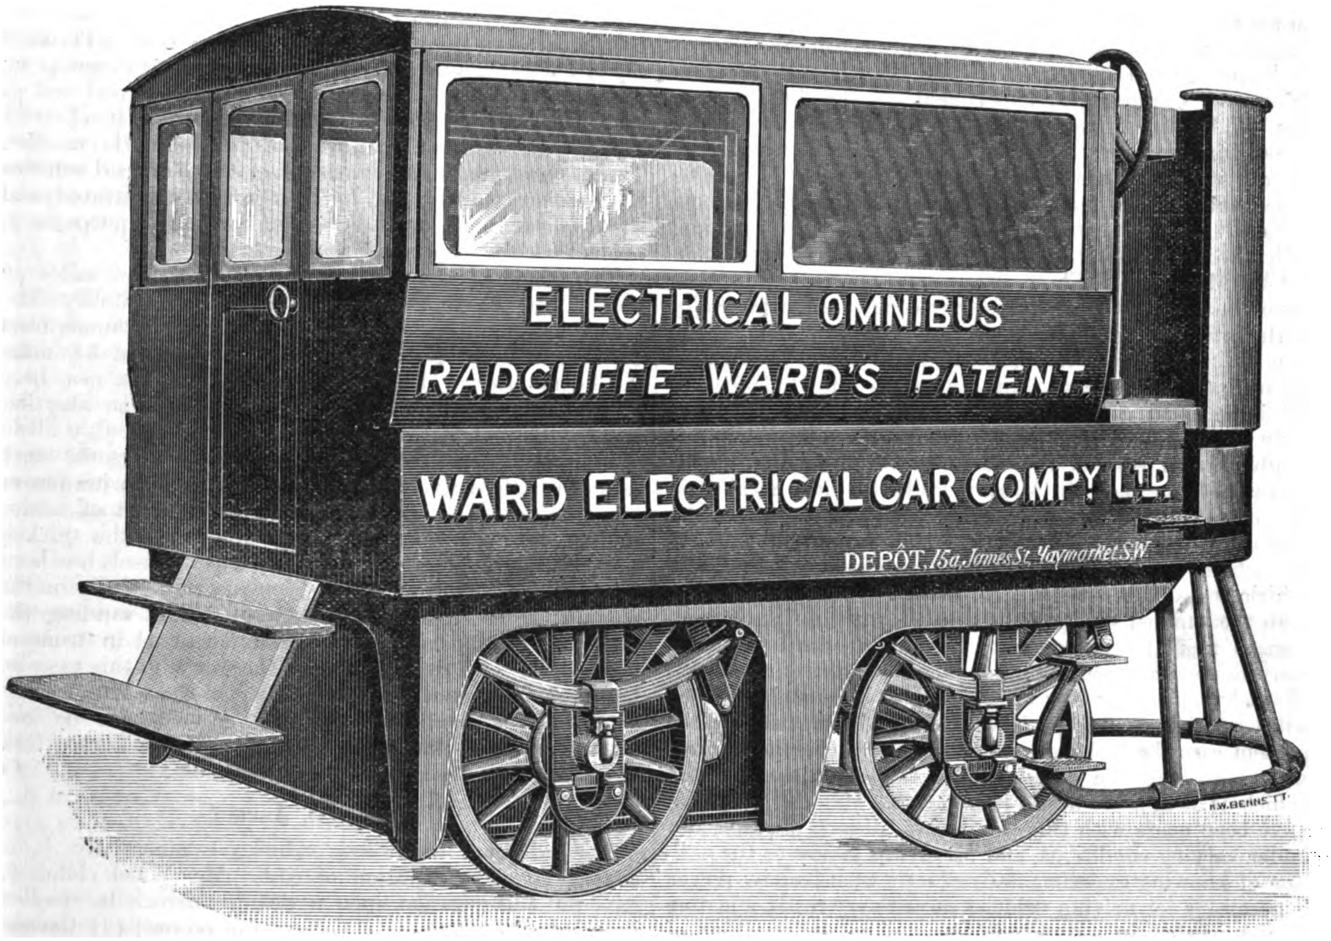
RADCLIFFE WARD'S ELECTRIC OMNIBUS.

Some little time ago we alluded to the running in the early hours of the morning of an electric omnibus—the first of its kind—along the roads of London. We are able this week to give a full description and illustration of this new departure in electric traction, at the same time calling attention to the capabilities of such a mode of traction for various classes of goods transport along the ordinary roads.

Until the end of last year there has been, in reality, no legal regulation dealing with carriages propelled along the streets by electricity. The only power which dealt with vehicles other than those drawn by horses on the streets was that given to the Board of Trade, under the Highways and Locomotives Act, which was passed to regulate the running of traction engines and steam rollers. It was in this that occurs what is known as the "red flag clause"—the Board of Trade regulations with reference to steam haulage specifying that the speed was not licenses can be obtained through any postal money order office under the Inland Revenue Department, and specify "carriages with four or more wheels and fitted to be drawn by two or more horses or mules, or by mechanical power." The definition is as follows:

> "The term 'carriage' means and includes any carriage (except a hackney carriage), drawn by a horse or mule, or horses or mules, or drawn or propelled upon a road or tramway, or elsewhere than upon a railway, by steam or electricity or any other mechanical power, but does not include a waggon, cart, or other such vehicle which is constructed and adapted for use and is used solely for the conveyance of any goods or burden in the course of trade or husbandry, and whereon the christian name and surname and place of abode or place of business of the person or the name or style and principal or only place of business of the company or firm keeping the same shall be visibly and legibly painted in letters of not less than one inch in length."

The first license for an electric carriage for ordinary roads under the new regulations has been taken out by the



to exceed four miles an hour, and that a man with a red flag must precede the engine by a distance of 400 yards. It has never been fully acknowledged by electrical engineers, or indeed insisted upon by the Board of Trade, that this act includes the regulation of carriages propelled by electricity, and we believe, as a matter of fact, there was no authority capable of objecting to the use of electric vehicles. Now, however, we are glad to say, this uncertainty is overcome. A careful consideration of the Act and of the Board of Trade regulations has shown that steam traction engines, or road locomotives—fuel-consuming engines—were alone in view in these regulations, every reference pointing to this special subject. The propulsion of ordinary carriages and waggons by electricity had never been contemplated, nor even conceived of, at the time these regulations were adopted, and the conditions are entirely inapplicable to the new demands. At the last session of Parliament, therefore, when a Bill for the Readjustment of the Excise Duties was brought forward, in the clauses where carriage licenses are referred to, special mention is made of carriages propelled by electricity, and at the present time two-guinea licenses can be obtained for these, as for any other form of four-wheeled carriage. The Ward Electrical Car Company, Limited, 15A, James-street, Haymarket, S.W., for the electric omnibus now described. The legal difficulty is therefore evidently practically at an end. For carrying passengers, such an omnibus would have also to be registered under the police regulations in the same way as other carriages plying for hire.

It is not to be supposed that upon merely taking out such a license any person who wishes to run upon the ordinary roads any electrically propelled vehicle can do so without further regulation. At the present moment there is no authority regulating such method of traction, but it is clearly to the interest of the public and all concerned that proper regulation under competent and independent authority should be carried out, after the needs and possibilities have been ascertained, and to stipulate, for instance, that all such carriages should be fitted with proper brakes to stop within a certain distance, and to carry such and such necessary appliances, etc. The Board of Trade have this matter under consideration, and a short special Act, brought in as a Government Bill, giving the Board of Trade the requisite power, would be all that is necessary.

With these preliminary remarks upon the licensing of electric carriages, we will pass to the history and descrip-

Digitized by Google

tion of the present undertaking. Mr. Radcliffe Ward has been connected with the introduction of electric traction from the very commencement. While engineer to the British Electric Light Company (who were working the Gramme patents) he assisted in what was probably the first experiment in electric power transmission, which took place early in 1879, for Captain Blanch Brain at the Trafalgar Collieries, Forest of Dean, Gloucestershire. In this case, the motor (a Gramme dynamo reversed) was stationary, and was used to haul coal trucks, and in so far this was not electric traction as now known, but the ability of the motor to work for these purposes was amply demonstrated. The result of these experiments was the establishment of an electric pumping station, which is still at work on the Forest of Dean. In the year 1881 the introduction of the Faure accumulator rendered possible the application of stored electrical energy to the purposes of tramway work, and the first electric car made was run by Mr. Radcliffe Ward on the Leytonstone line in 1882. M. Philippart, who had the introduction of the Faure battery on his hands, conceived the idea of applying it at once to tramcars, and arrangements were made with Mr. George Richardson, then chairman of the North Metropolitan Tramways Company, to experiment on the Leytonstone line. M. Philippart had this, the first electric car, constructed in Belgium and sent over to England, and the working of the car was in the hands of Mr. Radcliffe Ward. Numerous experiments were made, and some fundamental patents in variable-speed gearing, and details of the construction, which became evident on application in practice, were taken out by Mr. Ward. These experiments were only abandoned because of the unsatisfactory condition commercially of the only storage battery on the market. Some little time after, he started the construction of a car to run over the ordinary roads, but again, owing to the difficulty of obtaining good accumulators, this was dropped. In the early summer of 1887 he built an electric cab, which was exhibited and run on the roads at Brighton, and it was about this time that Mr. Magnus Volk also built his electric dog cart, which was described in the illustrated papers, and there excited the attention of the Sultan of Turkey, for whom Mr. Volk has recently constructed a similar vehicle.

In the summer of 1888 the first electrical omnibus commenced to make runs over the London streets in the early morning hours. This omnibus is not of the type that will be used for running, for which purpose a model omnibus will be designed, and special cells ordered to fit this. In the present case the best storage cells obtainable for the purpose were used, and the omnibus built to carry these, and the vehicle is as appears in the illustration. Many experiments have been made with this omnibus on all sorts of roads, and under varying conditions, and Mr. Ward is now in the position of knowing experimentally exactly what tractive power is necessary for driving vehicles on ordinary roads, a matter of the utmost importance in the design and working of electric vehicles of this kind, and which has until now been more or less problematical.

From time to time we have had a note about the working of the electric omnibus, and have watched with interest its progress, knowing that such work is the inception of a vast development of the practical application of electricity to ordinary civilised life. It is therefore fitting that a representative of the *Electrical Engineer* should have been the first to officially take a ride upon the electrical omnibus. Starting one morning last week, at 7 a.m., from a mews in Cromwell-road, South Kensington, we had an opportunity of judging the capabilities of the new car. It has the appearance of something between an ordinary closed bus without top seats, and a parcels delivery van, of course without horses, and is capable of seating twelve persons comfortably. The driver sits or stands in front, with a switch and resistance frame, and handle with worm-gearing to steer with, and a powerful foot-brake. It is powerfully built to sustain the weight of accumulators, which slide in trays under the seats.

The cells are the new type E.P.S. traction cells, and were the first set of this type made by the Electrical Power Storage Company. The motors, of which there are two, are Gramme machines, built by Crompton and Co., Limited, which have proved to be thoroughly reliable and efficient. They are connected with steel chain-gearing by Hans Renold, of Manchester, which are also thoroughly satisfactory. Mr. Ward has tried all the available methods—friction, chain, belts, and toothed wheels: they all have advantages for special conditions, but he finds the gearing he has adopted the best for these circumstances. The double-speed gearing alluded to has not been fitted to the first omnibus, but will be fitted for the cars to be used for ordinary work. The framework of the omnibus was constructed at the works of the Metropolitan Railway Carriage and Wagon Company, Limited, Saltley; the wheels are of special make to Mr. Ward's designs.

The car, which had been running the day before, started off easily and was run along Cromwell-road and Knightsbridge, turning into Hyde Park at the Albert Gate. The morning was bright and clear, and the ride was very pleasant. Not many people were about at this early hour, but the early tradesmen and workmen were of course moderately astonished at seeing the novelty. What it was, however, there could be no mistake about, for the lettering on the omnibus is large enough for all to read. Through Hyde Park was an easy and pleasant run; turning up by Hyde Park Corner the bus went on up the hill and out at the gate and along Upper Brook-street, across Bond-street into Regent-street, and thence into James-street, Haymarket. There is no doubt that the question of electrical road vehicles has been well tackled and its possibility demonstrated, and the application to ordinary work for many purposes is evidently only a matter of time.

The speed of the car is about six to seven miles an hour, about the same speed as that of an ordinary bus; a run has been made without stopping, for instance, from Notting Hill to Golden-square—a distance of 3½ miles in 30 minutes. The running of the car has not been attempted amongst the ordinary traffic in the daytime at present, but there would be no great difficulty about this, especially for heavy and slow-moving waggons—such as railway delivery vans, dustcarts, etc.—and with proper means of thorough control these would admit of taking their place in a crowded string of vehicles in the thickest London streets. The question of the slip of wheels has been freely tested, the cars having been run successfully on the slippiest days. This is mostly a matter of sanding the road, and a sand-tube can be easily arranged in front of the wheels. At the same time there are in this case no horses to slip down. Another point is the saving in dust from the droppings; the wear and tear will also be less, for this is greatly due to the pounding of the horses' feet, like eight sledge-hammers on the pavement.

Commercial Aspects.

The adoption of electric vehicles commercially is, of course, largely a question of cost. Mr. Ward claims to have put this question upon a definite basis. It resolves itself into three points: (1) the cost of power; (2) the cost of depreciation of the cells and car; (3) how much power it is necessary to expend to run certain weights upon the ordinary roads.

Definite estimates have been obtained from established manufacturers for the establishment of a power station for supply of current, with absolute guarantee of certain output at specified rates, by which it is undertaken that electricity can be produced at about 3d. per unit. There are several companies who will guarantee a certain depreciation of their cells, and will undertake contracts to keep them in repair at reasonable rates. The power necessary to drive such vehicles has now been ascertained, and the cost per mile for various vehicles calculated, and Mr. Radcliffe Ward claims that the result, all under guarantee from responsible manufacturers, shows a very considerable saving over the cost of horse vans. There is little doubt, if this means of traction proves successful in practical work, that the employment in towns and in connection with railway collecting and travelling generally the introduction of large numbers of electric vehicles would give an immense impetus to the electric industry.

For electric light stations it opens up a new source of profit. The dividends obtainable from electric generating stations will undergo a total change when there is the possi-

Digitized by Google

bility of selling large quantities of electricity during non-lighting hours for the purpose of operating vehicles, and private firms possessing dynamos might find a new source of profit.

With regard to the weight of the car, this is largely a question of rapidity of discharge of cells. The present car is rather heavy, but even here the weight per square inch surface of wheel upon the road is less than that of an ordinary bus, both being fully loaded. Ordinary buses take about two hours for a return journey. A battery of sufficient power which would be able to be discharged in this time would be very much lighter than those in present use, and there are indications that both the pasted and plain lead cells are approaching the necessary conditions of rapidity of discharge. The cells now used are extremely good and efficient, and there is talk of an improved plain lead cell which will give an extremely rapid discharge, and such a cell is the desideratum for this class of work.

The object of the Ward Electrical Car Company, Limited, will be probably not so much to sell as to contract to do work with electric cars. Neither do they intend, unless they see some special inducement to the contrary, to go themselves into the manufacture of electrical appliances. They propose rather to avail themselves of the existing electrical manufacturers. They are able at the present moment to make contracts for supply and maintenance of several different types of accumulators which will give satisfactory commercial results for street vehicle purposes, and, of course, many types of motors made by different firms are at their disposal.

The Ward Electrical Car Company are at the present moment discussing the question of electrically-propelled vehicles on a large scale with several of the most important railway companies, as however great the economy may be for omnibuses, it must be very much greater for vehicles such as goods and parcels vans, which stand about such a large proportion of the time they are out. The same remark applies to cabs, but in these the speed must be greater, and it must be seen how far the conditions are suitable for this work. The company also are going into the question of operating dustcarts and such vehicles. This, alone, is an enormous business. They are also considering the question of establishing lines of omnibuses in combination with the existing proprietors of omnibuses, or otherwise.

The first contract taken by Mr. Radcliffe Ward and handed over to the Ward Company is for an electric goods cart for a London tradesman. It is now building, and the trial trip will take place shortly.

It will readily be understood that in a new branch of work such as this many special devices and appliances have proved to be necessary for the commercial carrying out of the work, and the Ward Company consider that they have many patents which will prove of commercial importance in the affair. At the same time, when the practicability of electric traffic has been demonstrated, the application of motors to ordinary vehicles may become general, and will tend to the benefit of the whole electric industry.

ELECTROLYSIS OF COPPER SALTS.

BY ALEXANDER WATT.

(Concluded from page 59.)

43. *Ammonio-chloride of Copper.*—To prepare a bath from this salt, a moderately strong solution of salammoniac was added to a solution of protochloride of copper, the ammonium salt being added in moderate excess, and the resulting solution afterwards diluted with water. Electrolysed with the current from a single Daniell, a deposit of copper slowly formed on the edges only of a steel plate used as the cathode, but after a minute or two a partial film gradually spread toward the centre of the plate, but no deposit took place on the upper part of the cathode, while the back of the plate was only slightly coated at the side edges, no metal appearing on the lower edge of the plate. Two cells were next tried, when the deposit formed more quickly, but, as before, the film started from the edges of the plate, gradually converging towards the centre, but entirely avoiding the upper surface. When the plate was somewhat briskly agitated in the bath for about half a minute, the deposit gradually became dissolved off, leaving only a slight but very bright film of copper at the edges of the plate. This experiment was repeated with a freshly prepared steel plate, when, as before, the copper deposited while the plate was stationary in the solution, but gradually disappeared when it was kept briskly in motion. It was indeed very interesting to notice how effectually, though somewhat slowly, the deposited metal became dissolved from the plate, until at last only a narrow band, about one-eighth of an inch in width, was left, the upper outline of which formed a deep downward curve. With the current from three cells a very bright deposit formed on the edges of the plate, and gradually extended all over it, while the plate remained stationary; but when briskly moved about, the film again disappeared as before. A plate of steel received no deposit in this solution by simple immersion, but a clean strip of zinc, when immersed in the liquid, quickly received a bright coating of copper, which did not, however, alloy itself with the zinc, as is very generally the case, but formed a distinct film, which, being non-adherent, was readily removed from the plate by scouring with moist sand. On examining the anode, it was found to be coated with a lumpy green deposit of oxide.

44. *Ammonio-chloride of Copper with Chloride of Ammonium.*—A moderate quantity of the ammonium salt was afterwards added to the foregoing solution, when with the same current deposition took place more slowly, while the deposited copper was of a paler colour, and, as before, only adherent at the edges, where the film was brightest. In other respects, the addition of salammoniac did not appear to present any advantage.

45. *Iodide of Copper in Cyanide of Potassium.*—To prepare this solution, recently precipated and moist suboxide of copper was dissolved in a strong solution of cyanide of potassium, a moderate excess of the latter being afterwards added. The solution was then moderately diluted, and electrolysed with the current from three Daniells. With an anode surface about equal to that of the negative plate, copper deposited rather slowly, and was of a pale colour. The metal, however, adhered very firmly to the steel surface. A small quantity of the strong cyanide solution was next added, and a fresh steel plate immersed, when deposition took place more promptly, and the character of the film greatly improved, being not only better in colour, but also very bright, while, as before, the metal was perfectly adherent.

46. *Oxide of Copper in Acetate of Ammonia.*—Moist hydrated oxide of copper was digested in a strong solution of acetate of ammonia, in which it became freely dissolved, forming a dark blue liquid. The solution thus obtained was then moderately diluted with water, and electrolysed with the current from one cell, when a bright film of copper quickly formed on a steel plate; when the cathode was briskly agitated in the bath, the film gradually dissolved off, as in the case of the ammonio-chloride of copper solution. When the plate was allowed to rest undisturbed in the bath, a film of good colour was obtained, but the metal did not adhere well to the steel. The solution was afterwards diluted with water in small portions at a time, and it was found that the deposits from the weakened solution improved progressively so far as tenacity is concerned. When, however, the dilution had extended to about four times the original bulk of the liquid, the subsequent deposits became wavy and of very bad colour. A second cell was then connected, and a freshly-prepared plate immersed, which at once received a bright film of copper of good colour. After remaining in the bath about ten minutes, however, the primary layer of the metal became coated with a dark powder of a purple-brown colour, which was readily removed by the finger. On removing this loose, non-reguline deposit by scouring the plate with sand, the film first deposited became exposed, and was found to be firmly adherent. It was subsequently found that the deposits from the diluted bath did not become redissolved, as in the cases mentioned, when the cathode was briskly agitated in the liquid during the electrolysis; indeed, when a clean plate was im-

Digitized by Google

mersed in the solution, and kept constantly in motion, it became well coated with a bright, reguline and perfectly adherent film of copper. On examining the anode, it was noticed that small green lumps of oxide had formed upon some parts of the plate. These, however, redissolved in the liquid after a time, and the anode became perfectly clean. An excess of acetate of ammonia was next introduced, and a fresh steel plate immersed, when deposition took place so rapidly that it was found necessary to reduce the current to that of one cell, when more satisfactory results were obtained, the deposits being exceeding good in all respects, but more particularly when the cathode was kept gently in motion.

47. *Oxide of Copper in Bisulphate of Potassa.*—A solution was formed by digesting moist hydrated oxide of copper in a strong solution of the bisulphate, in which it was readily soluble. The resulting solution, which was of a pale blue colour, was afterwards considerably diluted with water and electrolysed with the current from a single cell and very small anode surface. The deposits first obtained with this bath were of a darkish colour, therefore the liquid was repeatedly diluted until the film assumed the characteristic colour of the metal, which was not effected until the solution had become exceedingly weak. It was hoped that a bath of this composition might be useful for coating iron, but it was found that the deposited metal, even in the weakest solutions, did not adhere perfectly to steel or iron.

48. *Suboxide of Copper in Citric Acid.*—To prepare a bath of this composition, recently prepared and moist suboxide of copper was digested in a strong and warm solution of citric acid, in which it dissolved freely. The solution was then moderately diluted with water. With the current from two cells, a very bright film of copper gradually formed on a steel cathode, which adhered very firmly to the plate, and resisted both hard scouring and burnishing.

49. *Suboxide of Copper in Hyposulphite of Soda.*—A strong solution of the hyposulphite was first prepared, to which was added, a little at a time, moist suboxide of copper, which soon became dissolved, forming a pale greenish-blue solution. This was afterwards diluted with about an equal volume of cold water. With the current from one cell, a very bright film of copper was obtained, which was found to adhere well to the steel surface of the cathode. A plate of zinc also received a very firm coating of copper in this bath.

50. *Chromate of Copper in Caustic Potash, etc.*—Recently precipitated and moist chromate of copper was digested in a strong solution of caustic potash, which freely dissolved it, and the liquid was afterwards diluted with about four volumes of water. No deposit of metal could be obtained from this solution with the current from three Daniells in series. A solution of the chromate in cyanide of potassium was next tried, but with no better success. Chromate of copper was afterwards dissolved in ammonia, but the solution failed to yield a deposit of copper with the current named.

51. *Oxalate of Copper.*—This salt being very sparingly soluble in water, only a very weak solution could be obtained. With the current from two cells, however, a pretty quick deposit was obtained upon a steel plate, which adhered very firmly. When a plate was left undisturbed in the bath for a few minutes, the loose purple-brown deposit before noticed again formed, proving that the current was too strong. A single cell was, therefore next used, and a new plate immersed, when deposition proceeded more slowly, and the film retained its reguline character. It was found necessary, however, in order to prevent the formation of the powdery deposit, to reduce the anode surface considerably—indeed, to the extent of about one-fourth that of the negative electrode. Under these conditions the metal deposited in a perfectly reguline state, and firmly adhered to the steel surface of the receiving plate.

52. *Oxalate of Copper in Ammonia.*—A quantity of oxalate of copper was first prepared, and the precipitate well washed and allowed to settle. The last washing water being now poured off, strong liquid ammonia was gradually added, the mixture being stirred after each addition until the oxalate was dissolved. The resulting solution, which was of a dark blue colour, was next diluted with about four times its bulk of water. With the current from a single Daniell no deposit of copper could be obtained; with two cells, however, a very bright and firmly-adhering film was received upon a steel plate. The anode surface immersed was rather less than that of the negative electrode.

53. *Oxalate of Potassa and Copper.*—A solution was formed by digesting moist carbonate of copper in a strong solution of binoxalate of potassa, and the solution then set aside to crystallise. The crystals were next dissolved in water, and tried with the current from one, two, and three cells in succession, but no deposit of copper took place until the third cell was connected, when a steel plate slowly received a film of copper, which firmly adhered to its surface. A copious green deposit of oxide formed on the anode, which dropped from the plate in the form of a powder, and collected at the bottom of the vessel.

54. *Subchloride of Copper in Chloride of Ammonium.*—Protochloride of copper was heated in a crucible to bright redness, and a portion of the resulting subchloride was then powdered and gradually added to a strong solution of salammoniac, in which it slowly dissolved. The solution thus obtained was afterwards diluted with water and electrolysed with one cell, a very small anode surface being immersed. A film of copper at once formed upon a steel cathode; after a few minutes' immersion, however, the film on the front of the plate was found to present a very beautiful iridescent appearance, in which dark green and blood-red patches were most prominent, while the back of the plate was uniformly coated with a deep blood-red film of remarkable beauty. This coloured film was readily removed by gentle rubbing with the finger, by which the film first deposited became exposed. The liquid was next considerably diluted with water, and the anode surface further reduced, when a newly-prepared steel plate promptly received a bright film of reguline copper; shortly after, however, the deposit again indicated a disposition to iridescence, to prevent which the cathode was kept gently in motion while in the bath, which effectually prevented the formation of non-reguline metal and a good deposit of copper was thus obtained, which was found to adhere to the steel surface with perfect tenacity. Attempts were subsequently made, by further dilutions of the solution, to obtain good reguline deposits upon the cathode without the aid of motion, but these were only partially succesful.

55. *Tartrate of Copper.*—A small quantity of this salt was prepared, but as it is very sparingly soluble in water, only a very weak bath could be obtained. This was first tried with the current from two cells, which, however, proved to be insufficient, so a third cell was added, and a rather large anode surface immersed, under which conditions a film of copper at once began to form upon a steel plate, the metal being very adherent. An addition of tartaric acid was next made, when the operation progressed somewhat more vigorously, a very good film being obtained in about a quarter of an hour.

56. *Phosphate of Copper in Tartaric Acid.*—A quantity of phosphate of copper was first prepared by adding a solution of phosphate of soda to one of sulphate of copper, the resulting precipitate being afterwards allowed to settle, the supernatant liquor then poured off, and the precipitate next washed in several waters. After removing the last washing water, a strong solution of tartaric acid was gradually added to a portion of the precipitated phosphate until it became dissolved, which was promptly effected by the tartaric acid solution. A moderate proportion of cold water was next added, and the solution was ready for use. With the current from two cells a very prompt and bright film of copper was received upon a steel plate, which very firmly adhered to it, and fully resisted the action of hard scouring with moist silver sand.

57. *Copper Phosphate in Citric Acid.*—A further portion of the precipitated phosphate of copper was next dissolved in a strong solution of citric acid, in which it was very freely soluble, forming a pale-blue liquid. This solution, after being moderately diluted, was electrolysed with the current

Digitized by Google

from two cells, when a bright deposit of copper rapidly formed upon a steel plate, the coating being exceedingly firm and of very good colour. An attempt was also made to obtain a solution of the phosphate in acetic acid, but this was found to have little or no solvent action on the copper salt.

58. *Ammoniuret of Copper in Bisulphate of Potassa.*—A strong solution of the bisulphate was first made, to which was gradually added recently precipitated and moist ammoniuret of copper, which readily became dissolved by the potash salt, forming a pale blue solution, which was afterwards diluted with about four times its bulk of water. With the current from a single cell a deposit of copper of a disagreeable dark colour quickly formed upon a steel plate, and it was found necessary to further dilute the liquid considerably to reduce the speed of the deposit. As it was found that the deposited metal under these conditions was non-adherent, the solution was abandoned.

59. *Copper Sulphate with Tartaric Acid.*—Having frequently noticed that the addition of vegetable acids to solutions of metallic salts formed with the mineral acids in some cases improved the character of the deposit, I determined to add to a moderately dilute solution of copper sulphate varying proportions of tartaric acid, in the hope that the mixture would yield adherent deposits of copper, which it is well known cannot be obtained from a solution of sulphate of copper *per se.* To prepare a bath, a rather weak solution of copper sulphate was first made, and to about 10 ounces of this solution was added 60 grains of tartaric acid, which was allowed to dissolve in the liquid. With the current from a single cell, and small anode surface, a steel plate promptly became coated with copper, which was found to be very adherent, and well resisted hard scouring with moist silver sand. After being rinsed and dried, the deposit was tested with a steel burnisher, the pressure of which it withstood without stripping in the least degree. It seems not improbable that a solution of this character, which might be modified by still larger but not excessive additions of tartaric acid, could be found useful for coating iron. It is generally understood that a nearly insoluble tartrate of copper becomes deposited from weak solutions of the sulphate to which tartaric acid has been added, but I may say that, with the exception of a very trifling deposit of the tartrate salt, I have not so far noticed any appreciable separation of the tartrate from the dilute solution referred to.

In pursuing the course of experiments which I have had the pleasure to record in these papers, I also electrolysed solutions of numerous other copper salts, but as the results obtained were in many instances of a negative character, it was not considered advisable to make any special reference to them. It is to be hoped, however, that from some of the solutions to which I have called attention may be selected several which the practical operator may deem worthy of further trial at his hands. In reference to such solutions I have thought it advisable to direct special attention, as some of the results which I obtained from them somewhat suggest the probability that a substitute for the cyanide of copper bath may be found amongst them. Again, I have endeavoured to point out which of the solutions tried is most favourable for yielding bright deposits of copper, as such solutions may be useful for coating certain small articles, or parts of metal work, for which a bright deposit of copper may be desirable. I may repeat here a statement made in the opening paper of this series—namely, that all the solutions named were worked at the ordinary temperature—that is, not artificially heated; but I may further add that the temperature of the laboratory in which the experiments were conducted (it being during the winter season) never exceeded 46deg. F. Those who have been accustomed to deposit copper from hot cyanide solutions, with all their pernicious effects on the health of the operator, will readily appreciate the advantages which would be derived from a harmless electrolyte that could be practically worked at the ordinary temperature of the atmosphere even in winter. If such a solution can be found amongst those which I have suggested, it will be a source of much satisfaction.

CORRESPONDENCE.

CORRECTION.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I note in your copy of my notes on "Design of Motors" one error, which I shall be obliged if you will correct.

In the expression for torque, equation (γ), C_a = *the total current flowing in the armature*, and not "the current flowing in one coil," as given in your copy.—Yours, etc.,

ALBION T. SNELL,

Electric Works, 19, Malden-crescent, Prince of Wales'-road, London, N.W., Jan. 22, 1889.

CENTRAL STATION LIGHTNING ARRESTERS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I should be greatly obliged to any of your numerous readers who would inform me what is the best simple form of central station lightning arrester to protect the dynamos; I have not heard of any that has been at all extensively used. Also what is used for "bearers" for overhead cables, and what are the "hangers" made of.—Yours, etc. A. I. E. E.

ELECTROLYSIS OF CHLORIDE OF SODIUM.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I observe that a paragraph quoted from the *Moniteur Industriel* has recently been running through the columns of the American journals to the effect that Mr. N. N. Beketov, a Russian chemist, has "made an interesting communication to the Technical Society of St. Petersburg on the subject of a *new system* of decomposition of chloride of sodium, which may have important results in the manufacture of soda ash and caustic soda." It is stated that Mr. Beketov made his first experiments, in 1885, according to the Hefler process, but the results not being satisfactory, "he has now treated electrolytically the salt in a state of fusion, and at this temperature, which with sea salt is 500deg. C., its conductivity is sufficient to produce electrolytic decomposition." With your permission, I will endeavour to prove that the so-called "new system" is nothing more than the reproduction of a process invented and patented by my brother, Mr. Charles Watt (chemist to the Australian Government), in the year 1851. In order that there should be no question as to the true origin of this method of treating chloride of sodium, I quote the following passages from my brother's patent, dated September 25, 1851: "The second part of my invention consists in a mode of preparing or obtaining the metals of the alkalies or alkaline earths by the united action of electricity and heat." The specification then goes on to describe the vessel in which the operation is conducted, "which is made of iron or other suitable material capable of bearing a full red heat. . . . The vessel is filled with dry saline matter, so that when it is in a state of fusion it shall reach the dotted line (indicated in the drawings which accompany the specification); the partition (also shown) keeps the eliminated substances from reacting upon each other, and also excludes the air from the compartment in which the metal is eliminated, the access of which would cause the metals to be oxidised. The vessel is placed in a furnace where it can be subjected to the action of a full red heat, and when the saline matter is in a state of fusion, contact is made between the decomposing vessel and the apparatus supplying the electric current. . . The fused salt is maintained at that temperature which will ensure the instantaneous volatilisation of the metal. . . The salts which I usually employ are the chlorides, iodides, or bromides of the metals of the alkalies or alkaline earths."

It will be obvious, from the few passages quoted, that Mr. Beketov's "new system" is really an old one after all; and I may say that this is not the first time that I have had to call attention to the reproduction of my brother's invention, as I think it but right that the public should know that there is no novelty in the decomposition of fused chloride of sodium by electricity.—Yours, etc.,

Balham, Jan. 18, 1889. ALEXANDER WATT.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of Mr. E. Graves, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. Wollaston, M.D., F.R.S., *and* Sir Humphry Davy, F.R.S. *The portraits of* Prof. D. E. Hughes, F.R.S., *and of* Dr. J. Hopkinson, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

THE INSTITUTION OF ELECTRICAL ENGINEERS.

Close upon the assumption of its new title, under which the late Society of Telegraph Engineers and Electricians will now be known, the council of this Institution have sent forth an edict which is sure to create considerable interest and possibly some unfriendly comments in more than one quarter. We refer to their decision of banishing the Press from the general meetings of the Institution. In future we and our contemporaries are not to report these proceedings. Such, at least, is the request conveyed by a letter from the secretary, which is before us. Says Mr. Webb: "I am instructed to inform you that the council have come to the conclusion that it is not desirable that the proceedings of the Institution's general meetings should be reported in the Press, and they request therefore that you will abstain from so reporting them." We cannot say that we were absolutely unprepared to find that the Institution desired to exercise some control over the way their meetings are reported—for one of our contemporaries had some weeks ago divulged proceedings at the council table which should have been kept private—but we were not prepared to be thus summarily deprived of a privilege which we have hitherto enjoyed. The dissemination of information in the quickest and most effective way is one of the principal duties of a journal, whether technical or otherwise, and accurate reports of the proceedings of a learned society are from this point of view most valuable to the readers of technical journals. Being thus suddenly debarred from giving our readers early information of what is brought before the Institution, we naturally ask ourselves, What have we done to incur the displeasure of the council and merit this sudden dismissal from our post? Well, we have done nothing detrimental to the interests of the Institution, and for this very reason we are inclined to the belief that this new rule is not conceived in a spirit hostile to the Press, which belief receives confirmation by the fact that the secretary promises to send proofs of the papers to be read before the Institution for publication in the technical Press. It is certainly annoying to find ourselves suddenly hemmed in by this new rule, but, after all, the council of the Institution of Electrical Engineers have a right to their opinions, and if they pass rules which are inconvenient to the technical Press it is only fair to remember that they were elected to look after the interests of the Institution and not after those of the electrical journals and their readers. As one of these journals, we dislike the new rule, but we admit that, from the Institution's point of view, it is a step in the right direction.

We are not in the confidence of the council, and even were it otherwise it would not be seemly for us to publish what by its very origin must be private information. We can therefore not say

PROF. W. E. AYRTON, F.R.S.

Although perfectly familiar with the difficulties and dangers of attempting to produce good portraits in papers, the work upon which has necessarily to be carried out under high pressure, we have determined to attempt to record not only the names but also the features of those who sit around Sir William Thomson, and under him guide the fortunes of the Institution of Electrical Engineers. The portraits now given will be supplemented from time to time by steel engraved portraits, several of which, as our readers know, we have had in preparation for months past. Prof. Ayrton is a type of those Englishmen whose energy has swayed the destiny of nations. For years past his name, together with that of his colleague, Prof. Perry, has been found in the front rank of those whose life-long aim is the progress of physical science. It is not our intention to attempt to give lengthy biographical notices. The men we have to deal with in this series are men well known to most of our readers—men moving among us, men to whom we look for guidance, and men to whom we look for information. Prof. Ayrton, we believe, first saw the light in Yorkshire. He was educated partly at University College Schools, and, subsequently to his gaining first place in the entrance examination for the Indian Government Telegraph Service, under Sir W. Thomson at Glasgow. After varied and excellent service in this department, he was in 1873 elected Professor of Natural Philosophy at the Imperial College of Engineering, Japan, where he remained till 1879. Soon after his return to England he was elected Professor of Physics by the City and Guilds Institute, and since then his career is familiar to us all. The Institution of Electrical Engineers owes much to the energy and the organising powers of Prof. Ayrton, for when he returned from Japan the society could by no torture of language be stated to have been in a very prosperous condition. Certainly he woke some of us up from the sleepiness into which we had fallen, and for this, if for nothing more, our best thanks are due. He has written and edited books, and contributed papers in a continuous stream to the learned societies, and at the same time has invented or improved various pieces of electrical apparatus. As a speaker he is exceedingly fluent, and possesses a complete mastery of his subject.

PROF. W. E. AYRTON, F.R.S.

Prof. Ayrton has been consistently in the front in all questions relating to electric light and power. His lecture at the Sheffield meeting of the British Association was a revelation to many, but perhaps his best work in this particular direction was his popular lecture at the last meeting of the British Association at Bath. This lecture was twice delivered to an overflowing audience. Perhaps the practical man connects his name more closely with simple and portable measuring instruments than with anything else, and no doubt such instruments have been largely manufactured and used from his designs. We are never very certain about mentioning Professor Ayrton's name alone, for his twin brother in scientific work has for so many years been so closely connected with him in all that he has done that the result should possibly always be stated as due to—no, not a torque, but a couple. Between them they have contributed a vast amount of information relating to motors, to dynamos, to telpherage, besides the work previously referred to on measu ing instruments. He is an excellent French scholar, and contributes articles to the French technical papers. As a professor he is getting around him some of the best talent of the rising generation, and we think this is the greatest possible proof of his fitness for such a position. Were we to add among his other idiosyncrasies that of a humorist, the impeachment would not be misplaced. But we think everyone will allow that the greatest compliment we can pay Prof. Ayrton is to say that he is Prof. Ayrton, and none other.

what may have been the reasons which caused the council to suddenly adopt an attitude which is apparently hostile to the Press. But if we do not know the reason, we can make a pretty shrewd guess, or, better still, think the matter out for ourselves, adopting for the purpose Charles Reade's excellent precept of "put yourself in his place." Now suppose our place were not the editorial chair in Salisbury-court, but a seat at the council table of the Institution of Electrical Engineers, and we should then view the matter in a very different light. We would at once recognise that the Institution has by its new title assumed an outward and visible sign of the rank to which it aspires. We would be anxious to see its status raised as much as possible, and cast about for means to accomplish this object, and try to remove difficulties which might stand in the way. Now there can be no doubt that indiscriminate reporting is not calculated to enhance the status of the society forming the object of these reports. The principle of allowing the sayings and doings of a society to be carried before the world by literary free lances totally beyond the control of the members of the society is hardly calculated to benefit the latter. On the contrary, it is likely to do harm. The perfect freedom to report, comment, and criticise may eventually engender a spirit of familiarity, and lead to the Press dictating to the council in what way it should manage the affairs of the society. We do not say that this has already taken place in the case of the Institution of Electrical Engineers, and we are quite sure that we ourselves have never been guilty of such an offence, but as we have put ourselves for the sake of argument into the place of a councilman, we must consider the eventuality that such a thing might happen. There is, however, another consideration of still greater importance. Electrical engineering in this country is now in full development. Scarcely a week passes without some large new electric light company being formed, each having its own particular system and stock-in-trade of patents, concessions, etc. Now these companies require financial support from the public, and to get it they are all anxious to show that their particular mode of going to work is the best. For this purpose the Institution of Electrical Engineers offers an excellent opportunity, provided always that the proceedings are widely and quickly published. If Mr. So-and-So wishes to get a gratuitous advertisement for his system or his company, he has only to wait his opportunity when a suitable paper is read and join in the discussion. If he be a fluent speaker, and understands how to advertise himself skilfully without overstepping the limits of scientific discussion, he will be able to say a great deal which, from a business point of view, will be very useful to him when it appears next week in a full report in the technical journals. His remarks may contribute nothing at all to the science or practice of the subject under consideration, yet he may continue to give the reader the impression that he knows the subject better than any other electrician, or that his company has the best system in the world for lighting, power transmission, or whatever the subject may be. The fact that he has been permitted to air his views at so influential a learned society as the Institution of Electrical Engineers gives him some sort of credentials when he wants financial support from the public, and the temptation to make the Institution merely a place for self-advertisement is therefore very strong. Suppress the reporting and this temptation is at once taken away. Mr. So-and-So will then know that his remarks can only reach those who are perfectly able to appraise them at their true value, and he will give way to other speakers who have something useful to communicate. A rule similar to that now introduced by the council of the Institution of Electrical Engineers has been in force for many years at the Institution of Civil Engineers, and with most beneficial results. The proceedings of this learned society are, beyond question, a pattern to all, not only in the practical value of the information conveyed, but also in orderly dignity. The meetings are always crowded, because members cannot get the information except by personal attendance, and although the advertising element is not totally absent, as it never can be where the majority of members are business men, it is not thrust prominently into notice. By following the lead of the Civil Engineers, the Institution of Electrical Engineers is not likely to have made a mistake in introducing this new rule regarding the abolition of indiscriminate reporting. Although as journalists we may dislike the rule, as members of the Institution we cannot but approve it.

THE "HOUSE-TO-HOUSE" COMPANY.

To the Editor of The Electrical Engineer.

Sir,—I should not have troubled to reply to the letter of the secretary of the above company had he confined himself to facts. But he tries to mislead your readers by what I can only describe as a perversion of the truth. He asserts that the Bath Corporation have "somewhat reluctantly" concluded a contract with me, etc. The exact contrary is the case. At my suggestion, the Corporation decided to entertain lighting all the principal thoroughfares with arc lamps, and grant facilities for the supply of private lighting. This question has been under their consideration for more than 12 months. Advertisements for tenders appeared for two successive weeks in each of the three technical journals. Each contractor was required to tender for overhead and underground mains. Ten tenders were received, of which the one sent in by myself (on behalf of a local supply company) being the lowest, both for overhead and underground mains, was accepted. All those who had taken the trouble to make themselves acquainted with the peculiar difficulties in the way of running underground mains in this city recommended overhead wires, and the majority of the Corporation being of the same opinion, that method was adopted. At the meeting when the final vote was taken, of a council numbering 54 members, only one gentleman voted against the contract being signed.

Digitized by Google

Considering that gas for the public lamps is charged only 1s. 11d. per thousand in Bath, the well-wishers of electric lighting throughout the country were surprised at the almost unanimous vote of the council. In common with others the House-to-House Company had the opportunity of tendering, but it does not appear to have answered their purpose to enter the field of fair and open competition. The following report of what took place when the application of the House-to-House Company was read, shows the feeling of the members of the Bath Council: Mr. Cox said that was an application for another company to go in and do the work which another company was engaged to do, and before they knew how it was to be done. They were in a transition state at present, and no interference should be allowed.—The Chairman: How can we, after arranging with one company, entertain proposals from another?—Mr. Sturges: We would not be allowed.—The Chairman: Well, I don't think so.—Mr. Mitchell then moved, and Mr. Sturges seconded, that the matter be referred to the Electric Light Committee. This was unanimously agreed to.

The opponents of electric lighting in Bath are delighted at the "dog in the manger" policy of the "House to House" Company, but the friends of electricity naturally regret it. The insinuation of the secretary of the "House to-House," to the effect that they possess the most perfect installation yet constructed, and are the only people capable of undertaking central station work, may be correct, or it may be their own opinion only. In any case I prefer to employ firms of standing and repute, who have already given me unqualified satisfaction, but whose names I purposely withhold, as I do not wish to make your correspondence columns a means of advertising any particular firm or company. The secretary of the "House-to-House," in true imitation of the "Maxim-Weston" Company in its worst days, refer to my calling in terms neither true nor complimentary. I am usually described as a boot and shoe manufacturer and leather merchant, but this gentleman (?) very politely designates me a "boot and shoe maker."

During the past four years my association with the electric lighting industry has been of a most agreeable character, and all professional electrical engineers with whom I have come into contact have been honourable business men and gentlemen, but the promoters of the "House-to-House" Company appear to be exceptions to this rule.—Yours, etc. H. G. MASSINGHAM.

1888.

(Concluded from page 51.)

CROMPTON AND CO. have been engaged during the year principally in carrying out central station work. The large station at Vienna has been completed, and is working in a thoroughly satisfactory manner, and they believe that the results obtained are, as regards economy and efficiency, far higher than has been obtained elsewhere. In England they have manufactured the plant for the extensions of the Kensington central station, as well as plant for other central stations not under their own control, and for abroad complete sets of central station plant have been supplied for Gothenburg, in Sweden, for Le Mans, in France, and for several small towns in our Australian colonies. The large dynamo machine for electric smelting for the Cowles Aluminium Company was set to work during the year, and after some difficulties, arising from the unexpectedly heavy currents which the machine had sometimes to carry, is now working perfectly, running continuously and giving its full output of 5,000 amperes and 65 volts. They have also made several large machines for electro-depositing work. As regards isolated sets of plant of considerable size, they have been for some time past carrying out the electric lighting plant for the new docks at Port Barry, and for the extensions at Cardiff. They made some very heavy sets of plant for ship lighting, notably for the P. and O. steamers and for the new White Star steamers. In addition to the usual routine work of supplying all kinds of electric lighting plant to their various agents, they have introduced a novelty in the shape of electric cranes, which have been a great success; one of these was recently described by us, so here needs no further mention. Generally speaking, the tendency of the year has been towards the manufacture of very large and heavy dynamo machines. Frequently as many as half-a-dozen machines of the 100-unit size would be seen in the shops at one time.

JOHN DAVIS AND SON, of All Saints Works, Derby, have been very busy in the electric lighting branch of their business during the latter part of 1888. In addition to plants ranging from 200 to 60 lights, they have done a good deal of extension work, including a large increase of arc light plant at Messrs. Bass, Ratcliff, and Gretton's brewery, Burton-on-Trent. In one colliery plant, in South Wales, the underground main roads are lighted throughout, the furthest lamp being considerably over half a mile from the dynamo.

Sunbeam lamps have been extensively used, and it may be of interest to note that in a dust-tight reflector fitting (a speciality which this firm manufacture) a 300-c.p. lamp will enable ordinary print to be read at a distance of 70 yards. They are now putting down the nucleus of a small central station, consisting of dynamo power (including spares) of 14 units, and an accumulator of seven units. In the power department they have in prospect a telpher line about one mile long, and an underground hauling plant to transmit about 120 h.p.

SIEMENS BROS. AND CO.—During the past year the various works carried out have been mostly of the ordinary kind, and there is little of an exceptionally important character to record. In the electric light department the company have either completely fitted or supplied dynamos, etc., to about 60 ships, about half of which belong to H.M. Government and the remainder to the principal passenger lines of steamers, besides fitting up several pleasure yachts for English and foreign owners. In the same department they have completed an installation at the Viceregal Lodge at Simla, and at three palaces and some bungalows of native princes in India. In England they have carried out several installations in mansions and private houses, and are now engaged on a contract for supplying electricity to the town of Bradford, in Yorkshire. In connection with this contract, Messrs. Siemens are using for the underground wires their new lead-covered cables provided with special high insulation and outer protective covering of sheet iron, which are found to be highly suitable for such purposes. In the cable department, among numerous orders of various descriptions, they have supplied and laid a cable across the Gulf of Mexico, on which work the ss. "Faraday" is at present engaged.

J. G. STATTER AND CO.—The year has been devoted, speaking generally, in standardising various sizes of dynamos, electromotors, and steam-engines, and arranging combined engines and dynamos. They have also brought out a new type of arc lamp—designed more especially to burn with moderate currents of from 6 to 10 amperes —a new cell tester, and a new magnetic cut-out. The firm's constant current dynamo, brought out in the autumn of 1887, has been improved and standardised, and is employed in several places, where it is doing good work. It is believed that this is the only constant-current dynamo—not employing a regulator in the field-magnets—commercially made and sold in England.

In transmission of power there is a large field of usefulness for constant-current machines and motors. A generator has lately been supplied for a constant current of 50 amperes at a variable E.M.F., according to the requirements of the motors it has to drive—the maximum is 350 volts, at a speed of 560 revolutions per minute. This generator is for series tramway work. They have also in hand a 20-h.p. generator and motor, the working conditions of which are somewhat peculiar. The generator will be driven by a turbine, which may vary its speed some 8 per cent., while the motor, which is a mile away, is required to keep its speed constant within 3 per cent. By means of their constant current principle, such conditions are satisfactorily met.

Dynamo work has been fairly brisk, especially during the latter part of the year. Machines of all size and voltages

Digitized by Google

have been supplied. In arc-light machines (constant current), machines of 1,200 volts, 800 volts, 400 volts, and smaller. In incandescent lighting, three 28-unit machines have recently been supplied—a pair for the Lyric Theatre and one for factory work. Twelve, nine, and six-unit machines have also been in fair demand.

In combined engines and dynamos several sets for ship lighting and mill lighting have been supplied, and the arrangement adopted of driving with short-link belt with setting in pulley (Jockey pulley) gives great satisfaction, and diagrams show that very little power is wasted. Both engine and dynamo are on one bedplate. The speed of the engine is in all cases moderate, being about 250 revolutions per minute in medium sizes, while that of the dynamo for the same set is 900 revolutions per minute. Both engine and dynamo are, therefore, under favourable conditions for economical working, and for minimum wear and tear. In electric light engines the work for the year, though not extensive, has been satisfactory. The type of engine made is what the Americans term an "automatic engine"—that is to say, the governor acts directly on the cut-off and is placed on the crankshaft. The engines are specially stiffly built for high steam pressures, and to enable them to withstand the wear and tear of long continuous runs the crankpin is lubricated by a centrifugal lubricator, and the whole of the lubricating arrangements are suitably arranged for the particular work. Although the central stations in England are few and far between, no less than two of them derive their power from "automatic engines," and negotiations are going on by this firm with the contractor for supplying a third station. Several projectors have been supplied to foreign Governments, and the patent diverging gear for varying the field, illuminated by the projector, meets with great approval. Three projectors supplied had automatic lamps—two for 100 amperes, one for 50 amperes. A special projector with our latest improvements is in hand for a foreign Government. The firm's measuring instruments are gradually extending in favour as their accuracy becomes more generally known. The business done in 1888 in these is about double that of any previous year.

WOODHOUSE AND RAWSON and the subsidiary companies have kept themselves well to the front during the past year. The principal company, Woodhouse and Rawson, Limited, has been very busy with a large number of installations for important people and firms, such as Messrs. W. H. Smith and Son, Peek, Frean, and Co., Lord Brassey, Messrs. Crosse and Blackwell, the Palace of Mysore in India, the Institute of Medical Electricity, etc. They also have done a good deal in working out new processes, such as Messrs. Elmore's copper depositing process, of which we hope to give particulars later on. As is known, they lay themselves out specially for new applications of electricity such as this.

The new price list brought out by the Woodhouse and Rawson Electric Supply Company of Great Britain, Limited, shows that this company also has been well to the front. The bringing out of a price list of this description does not only amount to a compilation of a certain number of pages of matter, but it means that the company must necessarily be doing a large business in these goods, as otherwise one cannot get a knowledge of the business which this catalogue shows the company to be in possession of, and low prices cannot be obtained unless one is able to place orders in large quantities. We hear that in the last six months the sale of electrical goods and goods connected therewith has increased nearly threefold.

Woodhouse and Rawson Electric Manufacturing Company, Limited, is chiefly known for its manufacture of incandescent lamps and instruments—such as switches, etc. The company have introduced during the past year a large number of new instruments—Wirt's rheostat, Pyke and Barnett's coils, Vernon Harcourt's standard instruments—such as pentane burner and holophotometer—Baker's wire-testing apparatus, and other specialties of a like nature. We hear that, on account of the very satisfactory way in which their new lamps with unflashed filaments are turning out, the company are about to reduce their standard efficiency from 3·5 watts per c.p. to 3 watts per c.p.

ELECTRICITY: LIGHT AND POWER.

BY HOLROYD SMITH.

(*Continued from page 39*).

As the term "lines of magnetic force" are "Greek" to those unacquainted with electrical science, it will perhaps be well to try and explain what takes place by the use of mechanical terms and illustrations (see next page).

Let A, Fig. 1, represent a drum or barrel with two long cords wound round it, the end of one cord passing round the pulley in the box S, the end of the other round the pulley in the box N. Now, if weights be attached, the cords will be pulled off the drum, making it revolve. Notice they are always pulling from the points, N and S. This may be taken as illustrating the magnetic attraction. Referring to Fig. 2, if A is a little water-wheel placed between two pipes, S and N, connected to a cistern full of water, and the water be allowed to flow from the spouts and impinge on the water-wheel, it would be forced round as long as the watersupply lasted. This may be taken as illustrating the magnetic repulsion.

If now we make the cistern a mass of iron and the pipes bars of iron, wound with copper wire, and put heavy masses of iron at the bottom, shaped as shown at S and N in Fig. 3, and instead of the pulleys or water-wheel we take an iron ring or cylinder also wound with copper wire, and allow a current of electricity to pass through the wire, the iron will become magnetic and the armature, A, will revolve in the direction indicated by the large arrows, because the magnetic force is acting as indicated by the little darts; the dotted darts represent the repelling action, the other darts the pulling action. The movement of a conductor in a magnetic field is omitted as too technical for this article. From this hasty survey of first principles, it will be seen, as stated at the commencement, that electricity can be produced without the use of chemicals for the decomposition of metals. Mechanical work can be turned into electricity, and electricity can be turned into mechanical work.

There have of late been so many exhibitions, not only in London, but also in the chief provincial towns, all of which have been lighted by electricity, that little need be said as to the display that can be produced by the electric light. In Manchester, last year, the brilliant illumination of the main building by arc lamps, the wonderfully charming fairy fountain in the grounds, and the cheerful homely light of the incandescent lamps in the numerous examples of house furnishing, show conclusively what can be done. And it is natural to ask, how is it that electricity is not more generally adopted for everyday use, if it possesses the many advantages claimed for it? The answer is, because all English people, whatever their political creed, are very conservative, and are slow to take up anything that is new. Again, we are so hedged about with vested interests and monopolies that it is difficult for new enterprises, needing public support and use, to get any foothold. In addition to this, until lately all electrical enterprise has been held in by the curb and snaffle of a prohibitive Act of Parliament, and therefore up to the present the successful installations are those undertaken by people able to pay for them, and using them on their own premises. As an example of this may be cited the Great Western Railway station, Paddington, the Grosvenor Gallery, London, and Wentworth Castle, the property and residence of T. G. F. Vernon Wentworth, which is, perhaps, the largest private installation in this country that has attracted the attention of electricians. One of the scientific papers, after giving full technical details, thus describes the lighting:

"The castle being a place of historic interest, full of valuable paintings and other objects of attraction, some further detailed description of the lighting of the principal rooms may be interesting. Commencing with the east wing, on the upper floor is the picture gallery, extending the whole length of the wing, 170ft. long and 24ft. broad, proportionately high, and is considered to be one of the largest in Yorkshire. The building being of a classical style, the walls are divided by numerous pilasters supporting the architraves which run round, and there are arches near each end, resting on white marble. This is lighted entirely with side lights from brackets of light and special design, in appearance resembling the stalks of flowers rising from a group of leaves and drooping over. Leaves of chased brass are placed at intervals on the stem, which terminates in a globular frosted glow lamp, specially made for this installation. The effect is heightened by mirrors placed between the pilasters, the lights on either side of these bending gracefully forward so as to be reflected. There are 107 lamps in this room; the appearance of the lights hanging from their graceful stems, either singly, double, or in groups like bunches of fruit, is exceedingly pleasing, if not unique. The pictures are well lighted, and the whole is seen to great advantage. Omitting the remainder of the upper rooms, we descend the grand staircase, which is lighted by a 7-lamp electrolier, and enter the Strafford Room, which is lighted by eight side lights. The walls of this room are lined with valuable pictures, as, indeed, are all the rooms on the ground floor,

Digitized by Google

of the east and south wings. Next follows the dining-room, lighted by twelve side lights, and also by a pendant electrolier for the dining-table, etc., containing three groups of lamps under three dome shades, which are capable of sliding backwards and forwards, and connecting with a centre by cone bearings, so as to allow of a rocking action in the electrolier when being drawn in one direction or the other. The weight of the electroliers is carried by insulated pulleys on an independent travelling line. This makes a most effective and brilliant way of lighting a dining-room table. Following on is the grand hall, decorated in white and gold, lighted by 16 side lights. These are for the most part placed in front of mirrors, and on light descending stems proceeding from lions' heads, in keeping with the other decorations. It may be here remarked that the whole of the east wall of this storey is decorated with mirrors, which have lights on each side of them. The lower floors of the eastern wing consist of several libraries and sitting-rooms, which are lighted with side lights on brackets of varied designs.

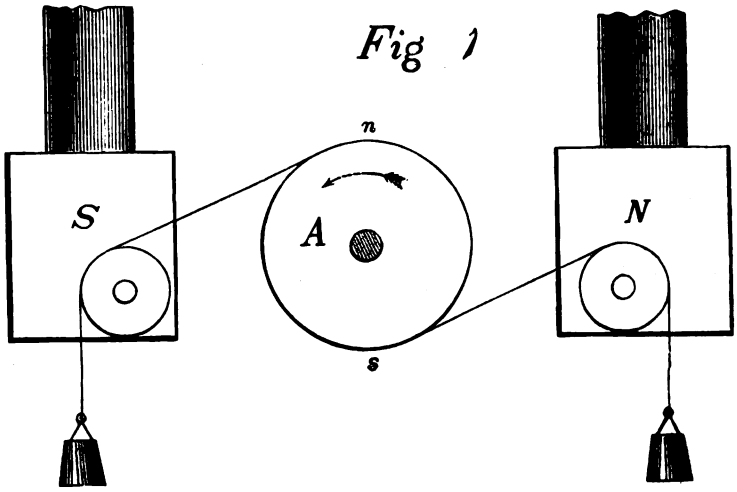
"The upper rooms, known as the Swan, Roman, Canopy, and Ark, are lined with tapestry (doors included), which is said to be unsurpassed. These are all lighted by side pendants of various colours, suspended from brackets above the tapestry. These rooms being also furnished as sitting-rooms, there are double-jointed brackets on either side of the fireplace for convenience of reading, as there are also in many other rooms. Referring to the other parts of the house, it may be remarked that the whole is well lighted, the kitchen, for example, having six pendant lights.

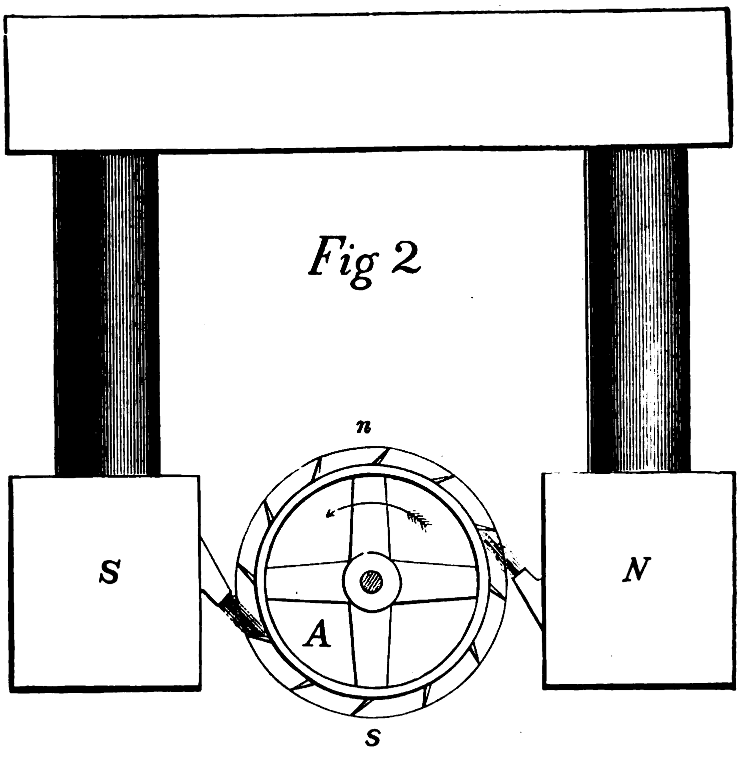
"The conservatory is lighted up for reading and writing, and for lunching, the effect of the light amongst the ferns and flowers, orange trees and foliage, being charming. There are sundry outside lamps for lighting up the approaches. The outside premises consist of a steward's house, stables and coach-houses, cow-houses, and farmyard; also the laundry, dairy, &c., with other appurtenances. . . . . .

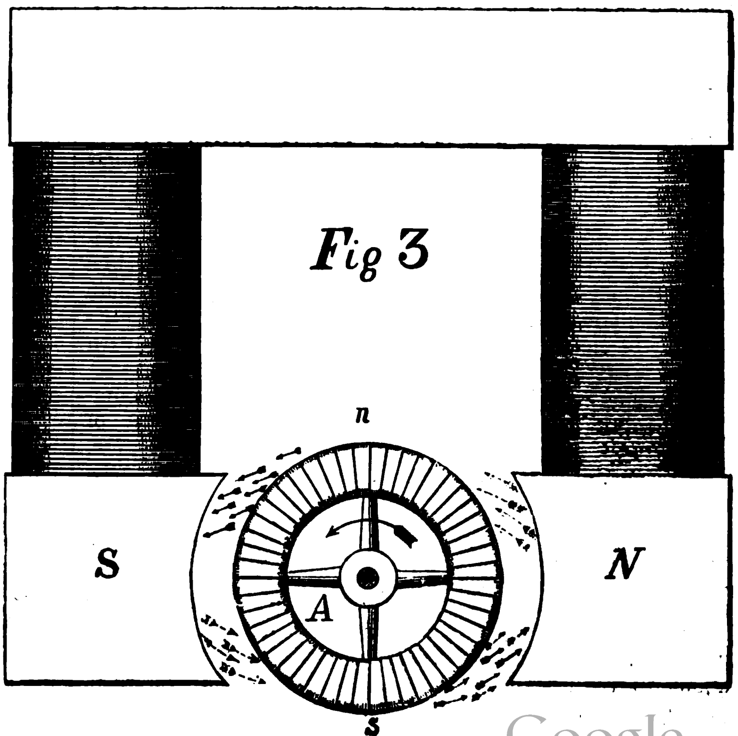
"The greatest care has been taken not only in the general arrangement, but in all the details, from the boilers to the lamps, to make it as perfect as possible in every respect, everything being of the best quality. In addition to the special arrangement for the simplification of the switches, complete instructions, mounted and framed, are placed near each switchboard; in short, the utmost pains are taken to make the whole most simple and intelligent. The installation was completed in December, 1885, and has run ever since without a hitch of any kind, and that, too, without the supervision of any electrician or anybody beyond those already employed on the estate. These facts are of the greatest importance, proving that the electric light can be so arranged as to be perfectly trustworthy, easily and inexpensively managed, and to give no trouble whatever. Its advantages as compared with the paraffin lamps, candles, and lanterns previously used are immense, and with such an example of beauty, brilliance, and elegance it is to be expected that ere long we shall see many of the large and historical mansions similarly lighted, and in this way the owners will secure for themselves the greatest comfort, convenience, and pleasure, whilst adding to their historic treasures that which is one of the greatest triumphs of the present century."

Hatfield House, the residence of the Marquis of Salisbury, now Prime Minister of England, may be taken as another example. Electric motors pump the water from the river to cisterns in the roof. Electric motors drive the circular saw and other machinery used at the homestead, and all the mansion is beautifully lighted with electric lamps. No smoke, no smell, no matches, very little risk of fire; just press a button, turn a knob, or pull a cord, and the whole room, corridor, hall, gallery, alcove, tower, or vaults are lighted as if by magic.

We are, indeed, realising "the fairy tale of science and the long results of time." Now, the surgeon, instead of groping in darkness or imperfectly reflected light, can pass a tiny electric lamp down the patient's throat, and see what is required. In Paris ladies frequently wear electric glow lamps in their hair, or as glittering dewdrops on artificial flowers, and the crowns of pantomimic fairies are often ablaze with electric diamonds; but, perhaps, the most effective use of electricity for dramatic purposes was when Irving, as Mephistopheles, watching the duel between Faust and Valentine, thrusts his sword between the combatants' swords, and, as they touch, blue sparks glint and







Digitized by Google

crackle, or when, in the Brocken scene, the little imps gambol about his knees, and, as he caresses them, bright flashes as from another and a lower world follow his hand.

All the illustrations given are for luxury or for the hope of gain. There are very few in this country for public utility. Perhaps the best example is on some of our lighthouses; yet though we have two at Dover, they are far surpassed by the light tower at Calais, where the three immense rays of revolving light sweep both land and sea in turn.*

(*To be continued.*)

ELECTRIC METERS FOR CENTRAL STATIONS.†

BY PROF. GEORGE FORBES, F.R.S.

There is no department of electrical engineering which has interested me and occupied my thought more than that of central station work, and the distribution of electricity from these centres throughout a town for the production of light and power.

It was before this society that I had the honour of classifying and developing the systems of distribution at the disposal of the engineer.‡ The position in which we now find ourselves is that, for extremely concentrated areas, a direct supply with continuous current dynamos, sometimes assisted by secondary batteries, and working on the three-wire system, is the most successful and the most remunerative; but for extensive areas the use of high-tension alternating currents in our mains, reduced in the houses by means of induction apparatus, is the most economical and flexible. This is the system which was first published and used by Gaulard and Gibbs. To take examples in the City of London. While we recommend the adoption of high-tension alternating currents by a company which is preparing to supply the whole of London with electric light, yet I felt that for the concentrated area bounded by Pall-Mall, Green Park, Piccadilly, and Haymarket it was far best to recommend the low-tension three-wire system; and we may look forward to seeing that central station the most satisfactory in the world from every point of view. This is owing to its concentrated area, and the large consumption of light in the district.

It always seemed that the success of such central stations depends largely on the working out of details in the arrangements—details in the mechanical parts, details in the electrical parts; and I have seldom visited any such stations without seeing new points of detail, and learning new facts about the causes which lead to success and failure.

In order that we may make as few mistakes as possible in our central station work, one must try to learn as much as possible from countries which have made a greater start than England. Thus I was led to visit the stations established on various systems in the United States; and lately I have done the same thing with respect to the most important of the central stations in Europe.

Both in Europe and America there is one maxim which I find is conclusively established. This is that the best paying stations are those in which the electricity is charged for by meter, and not at so much per lamp per annum. Both these systems are in use, but companies who have used both give their undivided testimony in favour of charging by meter.

I propose to deal with this important point of detail to-night, and to tell you something about the working of different types of meters in the United States as well as in Europe.

Now, first let us settle the question what it is we want to measure. Both with gas and with electricity, if the company supplies burners or lamps it would be most desirable to measure the light given off. But this plan is not likely to be adopted in England. The private consumers generally supply the burners or the lamps. Hence, what we come to is that we want to measure the gas or the electricity consumed. We want to measure its light-giving power. To do this we must know the quantity consumed and its quality. With gas, the latter is impossible to measure in the meter. We can only measure the quantity of gas consumed. We cannot measure its pressure nor its purity, nor the quantity of air or sulphur combined or mixed with it. These points are left to inspectors to determine, who shall insist upon a standard being maintained.

With electricity it is different. When we have measured the quantity consumed there is only one quality which can exist, and that is its pressure. If, then, our meters measure the quantity consumed, and inspectors keep watch to see that the pressure is always maintained constant, the consumer's interests are amply looked after.

Now it has been suggested that we really ought to measure, not the quantity of electric current which is consumed, but the quantity of energy. Now, the energy is the product of the quantity by the pressure, and could easily be measured if desired. There would be no object, however, in doing this. A deficiency of pressure is certainly undesirable, because the lamps burn less brightly, and the customer should be charged less. But, on the other hand, an excess of pressure is equally objectionable, because it injures the lamps, and it would not be fair to charge the customer more for the quantity he uses under these conditions. The only fair way is to do as with gas—*i.e.*, to measure the quantity used and guarantee the quality—*i.e.*, the constancy of pressure. This should never vary more than 4 or 5 per cent. at the most. For perfect lighting a variation of 2 or 3 per cent. only can be allowed.

I intend to direct your attention to various kinds of meters which have been put into actual practice, but before doing so it will be well to point out some of the desiderata in a perfect electric meter. I will deal with these in order.

1. *Accuracy.*—The meter must be at least as accurate as an ordinary gas-meter. In fact, that standard is rather low for modern requirements. The question of accuracy is two-fold. First the readings of the meter must be accordant for all rates of supplying electricity within its range, and secondly, the indications of different meters must be consistent. This latter point is largely one of manufacture, so that it must be easy to manufacture the instruments in large quantities, all exactly similar.

2. *Range.*—It is desirable that the meter should be capable of working accurately over a large range of current strength. It would undoubtedly be desirable that the meters, made for the largest currents which can be used on a circuit, should also be capable of indicating correctly when only one lamp is in circuit. So far as I am aware, no electric meter has been invented fulfilling this requirement. It has often been proposed, with circuits of very many lamps, to have two meters—one for small currents, and the other for large ones—and to switch in the latter automatically when the current exceeds a certain amount. Any such arrangement which involves an occasional use of a contact-breaker is objectionable, owing to the sparking and consequent deterioration of the contact. A far better plan, in the existing state of things, is to wire the houses in separate circuits of 20, 40, 60, or 100 lamps, according to the effective range of the meter adopted.

3. *Consumption of Energy.*—Energy must not be consumed by the meter to such an extent as to diminish injuriously the voltage supplied to the lamps. The wiring of a house diminishes the voltage at the maximum about 2 per cent., according to present practice. A meter ought not to increase this loss by more than ½ per cent.

4. *Simplicity.*—The meter should be simple to construct, and not liable to get out of order. Extreme delicacy in moving parts is to be avoided when possible.

5. *Durability.*—It is essential that no parts of the apparatus are liable to wear out rapidly.

6. *Attention.*—Other things being equal, that meter is the best which requires least attention. Any winding up of clockwork is objectionable, and the necessity of removing the meter or part of it from the consumer's premises should be avoided.

7. *Registration.*—The meter should register in a clear manner, so that the consumer can read it at any time and check its accuracy. A system of geared wheels with indexes and pointers, like a gas-meter, is very convenient.

8. *Testing.*—A point of some practical value is that it should be an easy matter to test the meter, and that the operation should not occupy much time.

9. *Cheating.*—With some meters the process of cheating is easier than with others. The possibility of short-circuiting the meter is common to all, and can be obviated. Some meters can be retarded by placing a magnet near them, others by heating them, others by putting them out of level. This last can be prevented by securely fixing the meter to a wall or floor.

10. *Economy.*—A meter will not be practical if it entails a large rental, and so adds much to the quarterly bill.

11. *Freezing.*—A meter which contains a liquid which can freeze is objectionable in any but warm countries, since a lamp or other resistance must then be put inside it to keep it warm, and this is a constant source of waste of energy.

12. *Alternating and Continuous Currents.*—Some meters are only usable with continuous, others with alternating, currents. A meter which reads with equal accuracy for both kinds has a double value. Many stations supply both classes of currents, and it is less inconvenient to deal with only one type of meter.

13. *Number of Alternations.*—Meters for alternate currents ought to indicate with equal accuracy, whatever be the alternations per second. Otherwise irregularities will occur, and also the supplier of electricity can cheat by altering the number when under test, and also when at actual work.

14. *Contact-breaking.*—No contact-breaker of any electric circuit should be allowed in a meter, because such contacts deteriorate with use.

15. The meters should be so substantial that they can be sent by rail without accident.

No one meter fulfils all these requirements perfectly. But

* In one respect we do surpass our neighbours, viz., in the employment of powerful electric lamps as search-lights on most of our men-of-war. † Paper read before the Society of Arts, January 23. ‡ Cantor Lectures, 1885.

Digitized by Google

all the meters which I am going to describe fulfil many of them, as they all have done good practical work on central stations.

In all the meters which I have to describe the registration is effected either by moving mechanical parts or by electrolytic decomposition. In most of the mechanical meters a certain dynamical principle has been employed to guide the inventors to an accurate instrument for different strengths of current. I will now explain this. In the class of meters I allude to the electric current sets some mechanism in movement. Now, we all know that generally the work done by a current in a given time varies as the square of the current. Thus, the electrical force tending to drive the mechanism is proportional to the square of the current. Such mechanism would increase its speed indefinitely under the influence of such a force if there were no friction opposing the increase of speed. In the meters I allude to the friction of the air or of a fluid is opposed to the driving force of the electric current. This resistance increases as the square of the velocity. The electric force goes on increasing the speed of the mechanism until the opposing friction equals the driving force of the electric current. But the friction varies as the square of the velocity, and the driving force varies as the square of the current. Hence in all cases where the mechanism acquires uniform speed, the square of the velocity is proportional to the square of the current—in other words, the velocity varies as the current. Now, the indications of such an instrument as shown by an index gives the number of revolutions of the mechanism in the period of testing, which means the velocity multiplied by the time, and this is proportional to the electric current multiplied by the time. Hence, the index marks the total number of ampere hours, or the total number of Board of Trade units which have passed through the instrument.

Edison Meter.—In describing the different meters, I will begin with the Edison meter, not only because it was the first to be used, but also because it has done a larger amount of useful work in central stations than any other meter. In its original form, as shown in the Paris Electrical Exhibition, in 1881, it consisted of two copper plates suspended from the two ends of a balanced beam in a solution of sulphate of copper. A continuous current passing through from one plate to the other decomposed one plate and deposited copper on the other. This one eventually got heavy enough to tip over the balanced beam. This mechanical action had two effects, (1) it registered a unit on the counting mechanism, and (2) it reversed the direction of the current, and now the lighter plate received the copper deposit, and so the process went on continuously. It was not possible to pass the whole current in this way through the solution, because the resistance would be too great. Hence the depositing cell was put as a shunt on the main current. Several objections to this type soon became apparent in practice: (1) When the temperature of the air was high, the resistance of the solution diminished, while the resistance of the alternative metal path increased. Hence with high temperatures a greater proportion of the total current went through the meter. (2) It was soon found that a make and break, as necessitated by the reversals in the direction of the current, led to endless trouble, and the ingenious method of counting had to be abandoned. In the improved meter, zinc is the metal employed, and sulphate of zinc the solution. The current always goes in one direction. Fresh plates are inserted as they wear away. To determine the consumption of electricity, the meter is carried away and the loss of zinc in the positive plate is weighed, and the consumer charged for a proportionate number of units of electric current; 1-1,000th of the total current passes through the zinc solution. In series with this solution is placed a copper resistance, so arranged that with a rise of temperature the fall in resistance of the solution equals the rise in resistance of the copper, the alternative path being of german silver. Thus between 4deg. and 34deg. C. the same fraction of the current passes through the solution. To prevent freezing, an incandescent lamp is always kept burning in the case containing the meter during the months that freezing is possible.

The range within which the meter is said to be accurate within 3 per cent. is from 5-fold to 10-fold—*i.e.*, if one ampere is the lowest current for which it is accurate, then 5 or 10 amperes is the maximum current for which it is accurate.

Now, you may say that this is not exactly the kind of meter we require, because customers cannot check the weighings, and are absolutely dependent on the good faith of the company supplying the electricity. It has also been argued that the shunt arrangement cannot be perfect with varying temperatures. Well, I can only say that the meter in practice is found to do good work. I agree entirely with what Mr. Edison said to me about it. He said: "It is not an ideal meter, but it is simple and effective, and gives general satisfaction wherever it is used." I endorse this opinion. But the managers of central stations where it is used have given me higher estimates still of its value. They say that customers are all quite content with the manner of reading it. As to accuracy, many customers have kept accurate tally of the lamp hours which they have consumed, and compared it with the charges by meter, and have often come within 2 or 3 per cent. At the splendid central station at Milan, which I lately visited, this meter is in constant use, and is much appreciated by the company. They say that the expenses of maintaining the meter department are not large when the whole thing is well organised. The total number of ampere hours sent out from the station, as measured by the ampere-meters, agrees with the meter accounts within 3 per cent. This station, which I have carefully inspected, is an admirably conducted one, and embraces three systems—the Edison low tension, the alternating high tension, and the Thomson-Houston arc lamp systems.

(To be continued.)

THE INSULATION RESISTANCE OF ELECTRIC LIGHTING INSTALLATIONS.*

BY PROF. A. JAMIESON, F.R.S.E., M.I.C.E., MEMBER.

Insulation Resistance of Land Lines and Submarine Cables.—In the early days of telegraph land lines and of submarine cables, *insulation resistance* was neither definitely specified for, nor accurately measured during the various processes of manufacture and maintenance. A few failures, however (in some cases dearly bought), soon impressed electricians with the necessity for paying more attention to this important quality, and they were not long in demanding from contractors the minimum of insulation resistance which would enable their lines to be worked with success. Not only are careful insulation tests now made during the manufacture of insutators and the erection of the land lines under the British Postal Telegraph Department, but "daily tests" are taken of all the more important lines. The minimum insulation resistance which each insulator should have depends upon the length of the line. For a line of 100 miles long, each insulator is expected to give a resistance of 500 megohms, whereas for a line of only ten miles 50 megohms is considered sufficient. When a line has been erected and put into working order, it is usual to fix upon a minimum standard insulation resistance per mile. If the measured value at any time falls below this standard, then the line is considered faulty, and steps are taken to remove the fault. The Post Office standard is 200,000 ohms per mile. In the cases of subterranean land lines and of submarine cables, an even still more rigid and careful system of inspection and of testing is now carried out during the manufacture of the cores and cables. The results are invariably reduced to an insulation resistance per unit of length at a standard temperature. The following extract from the specification of a successfully made and laid cable will serve to illustrate this: "The insulation resistance per knot of the gutta-percha core shall not be less, when tested at 75deg. Fah., than 300 megohms, 14 days after manufacture and after two minutes' electrification. If the resistance of any portion of the gutta-percha (reduced to 75deg. Fah.) at any period of the manufacture fall below the above specified limit, the cable to be rejected." Throughout the whole of the operations of coiling and uncoiling a cable into the shore and ship's tanks, during the laying, and for ever after during its existence, the insulation resistance is periodically measured and tabulated.

Results of Neglecting Insulation Resistance in Electric Lighting.—We have been induced thus to particularise the extreme care and attention which is now considered so absolutely necessary in the case of land lines and of submarine cables, because the industry of electric lighting has just passed through a similar experience to that which these industries met with in their earlier days. When the industry of electric lighting was first beginning to take root in this country, electric light engineers pooh-poohed the idea of accurately measuring the insulation resistance of any part of their work, and they invariably turned a deaf ear to the timely warnings of telegraph engineers and electricians. Experience has, however, taught them, as it did their elder brothers, that good uniform insulation resistance throughout an installation is of immense importance, and that it cannot be obtained without careful attention to details and a rigorous system of testing during manufacture, erection, and after completion. If an installation is not well insulated throughout, leakage of the current takes place, and consequently waste of power and money; electro-chemical action sets in where damp or liquids are present, and the conductor is thereby eaten through or a short-circuit occurs, which for a time stops the whole of the lighting. Discredit thus not only falls upon the contractor, but others are frightened from employing the electric light, to the detriment of the industry as a whole.

Necessity for Discussing a Standard of Insulation Resistance.—The terms usually employed in regard to the insulation resistance of an electric light installation are that it shall be "good" or "perfect," according to the fancy of the party purchasing the plant or of his adviser. These terms have, however, no specific meaning, and are therefore very variously interpreted. No doubt the society has had this subject before them in committee when drawing up their set of rules for the "prevention of fire risks"; but the Institution as a whole has never had an opportunity of discussing it, and thereby of impressing its members and the public generally with its importance, and the necessity for observing some minimum standard of insulation resistance. The writer had his attention directed the other day to a communication read before the International Society of Electricians, Paris, in November last, by M. Picou, wherein that gentleman ably analysed this question, and proposed a rule based upon tests of short lengths of cotton-covered insulated wire. He has not had an opportunity, however, of learning the extent and the nature of

* Paper read before the Institution of Electrical Engineers on Thursday, January 24th, 1889.

Digitized by Google

the discussion upon M. Picou's paper, and he can only, therefore, place his rule before the members, along with a few other rules, and leave them to form their own opinions, guided by their practical experience.

General Propositions.—The following points will no doubt be readily admitted in regard to insulation resistance of electric lighting installations:

1. That owing to the comparatively low resistance of the conductor circuit of ordinary electric light installations on the parallel incandescent system, the minimum standard of insulation resistance does not require to be nearly so high per unit of length as in the case of submarine cables.
2. That it should be directly proportional to the E.M.F. of the generator, or difference of potential between the conductor and earth or between the forward and return conductors.
3. That it should be inversely proportional to the total length of insulated conductor, or to the total current, or to the number of lamps in circuit.
4. That, whatever rules or standards of insulation resistance may be adopted, they should be applied, not only to all the conducting wires, but also to the dynamo, the lamps, and all the fittings, or, in other words, to the *whole* circuit.

Rules.—1882 Set of Rules by Society of Telegraph Engineers and Electricians.—In May, 1882, in the first set of "Rules and Regulations for the prevention of fire risks arising from electric lighting" issued by the Society of Telegraph Engineers, no standard of insulation resistance or of minimum leakage is recommended. All that we find there on this head is: "The difficulties that beset the electrical engineer are chiefly internal and invisible, and they can only be effectually guarded against by testing or probing with electric currents"; "All wires used for indoor purposes should be efficiently insulated," etc.; "The insulation of dynamo coils and conductors should be practically perfect"; "The value of frequently testing the apparatus and circuits cannot be too strongly urged," etc.

Four years ago, even, the writer is not aware that any published rule existed, or that any specification contained any definite rule for the insulation resistance of any part of any electrical installation.

Admiralty Rule.—About 1883 or 1884, however, the Admiralty officials requested that the insulation resistance of the dynamos supplied to them should withstand the test of stroking the free end of a conducting wire (the other end being connected to either pole) over any part of the framing without showing any signs of a sparking when the machine was driven at its normal speed. The writer does not know whether they still insert this rule in their specifications, or whether they have modified or improved it; but at best it is only a rough-and-ready test, and gives no indication whatever as to the precise locality of a fault or its value in ohms.

Workman's Tests.—The only test applied by contractors when wiring an installation was, and often still is, that of simply inserting

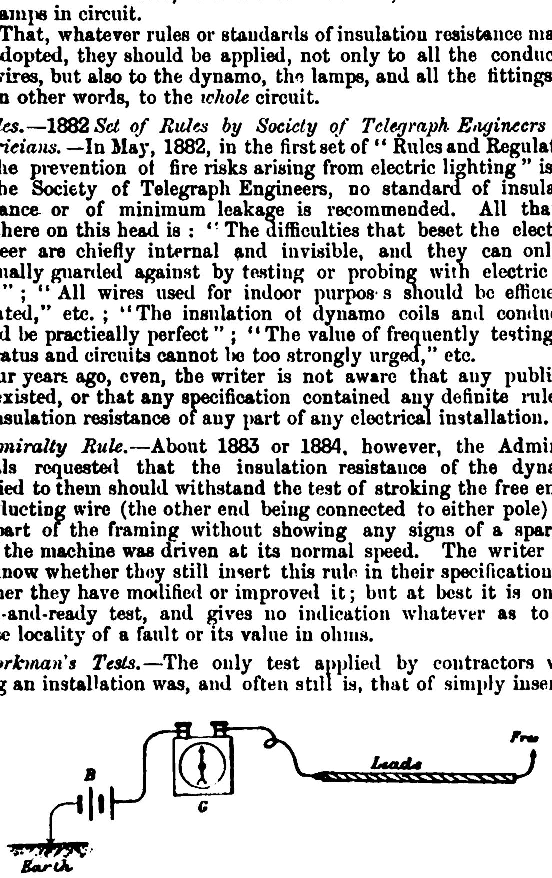


Fig. 1.

an ordinary lineman's detector or galvanometer, G, between a battery, B (of one or two cells), and the leads, with the other end or ends freed, as in Fig. 1. If the galvanometer gives no deflection, or a very small one, then the section is passed as all right.

This is such an exceedingly simple and handy test for workmen that it can scarcely be improved upon, but it gives no precise indication whatever of the resistance in ohms, of the dielectric, or of the fittings. It simply informs the observer whether there is a bad fault or not. He can also find out by it whether the continuity of the conductor is complete, by earthing the further end; and he can also ascertain whether there is a short-circuit or not between any two or more "forward" and "return" leads by connecting up his apparatus as shown in Fig. 2.

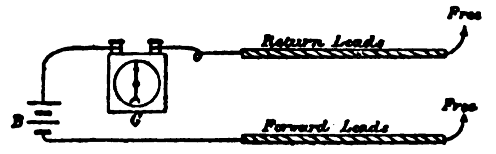

Fig. 2.

In 1884 Messrs. Wm. Denny and Bros.' electrician used a small portable magneto-electric machine and sensitive bell—the same as telephone companies employ—instead of the above-mentioned galvanometer and battery. If the bell rang, a fault existed, and its position had to be found out; if it did not, then all was supposed to be right. He, however, in addition to this merely workman's test, applied a more exact test by Wheatstone bridge, and thus obtained the insulation resistance of the whole or of any desired portion of the circuit and the fittings in ohms.

Prof. Jamieson's Rule.—In 1884, whilst testing the electric light wires and fittings of some ships, the writer first drew up his rule, which has been published in the last three editions of Munro and Jamieson's "Pocket Book of Electrical Rules and Tables." He had previously (since 1881) tested, by Wheatstone bridge, etc., the insulation resistance of a number of land and ship installations, and was rather surprised at the variety and lowness of the dielectric resistance, for his ideas of insulation resistance had been somewhat magnified by seven years' experience with submarine cables. At first, he could not get contractors to come up to his rule, but he was much gratified about this time by the enthusiasm and interest which Messrs. W. Denny and Bros.' electrician took in the matter, and by finding such good results in his tests of their ships' lighting leads, which results so far surpassed the demands of his rule that he decided to adhere to it. Since then he has had much less difficulty, and when care and attention to cleanliness in jointing, to the fixing of wires and fittings, as well as in the manufacture of dynamos, are observed, he has frequently found that the insulation exceeded the demands of his rule, which is as follows: "A careful insulation resistance test of each circuit, and finally of the whole of the circuits (including all switches and terminals, but not necessarily the lamps) joined up together, should be taken by the method described above,* and not passed unless the resistance is at least equal to ·1 Ω per lamp for every volt employed. The insulation resistance of the dynamo coils should be equally good.

Put into formula shape, the rule is—

$$R_I = k\frac{E}{N_L},$$

where R_I = the total insulation resistance of the whole or any part of the lamp circuits or of the generator in ohms;
k = a constant (·1 Ω = $\frac{1}{10}$ Ω = 100,000 ω) found from actual tests of several well-erected installations;
E = E.M.F. of dynamo or installation in volts;
N_L = number of lamps (16 c.p.) on each circuit or on the whole circuit.

The insulation resistance is therefore here taken to be *directly* proportional to the normal E.M.F. of the dynamo, and *inversely* proportional to the number of 16 c.p. lamps in circuit. The difficulty of ascertaining the precise length of the mains, sub-mains, leads, and dynamo windings led the writer to substitute the number of lamps in circuit for what might at first sight appear to be the more exact term in the denominator—viz., the length of conducting wires employed. Although not stated in the above quotation of his rule, the writer usually applies the same test for the resistance or percentage leakage of current between the whole system of forward and return wires; also between the dynamo armature with field-magnet coils in circuit and the frame or body of the machine, as well as between the series and shunt-magnet coils if the dynamo is of the compound or series-shunt type.

The following example and table will make the application of this rule clearer:

Suppose that we have an installation of 100 lamps of 16 c.p. each, and that the normal difference of potential between the terminals of the dynamo is 100 volts, then the insulation resistance should not be less than

$$R_I = k\frac{E}{N_L}$$
$$= 100{,}000\,\omega\,\frac{100\,v}{100\,L}$$
$$= 100{,}000\,\omega = \cdot 1\,\Omega.$$

Table of Insulation Resistances required by Jamieson's Rule. For 16 c.p. Lamp Circuits and Dynamos.

Number of lamps in circuit.	50-volt lamps.	65-volt lamps.	80-volt lamps.	100-volt lamps.	110-volt lamps.
	Ohms.	Ohms.	Ohms.	Ohms.	Ohms.
1	5,000,000	6,500,000	8,000,000	10,000,000	11,000,000
10	500,000	650,000	800,000	1,000,000	1,100,000
20	250,000	325,000	400,000	500,000	550,000
40	125,000	162,500	200,000	250,000	275,000
50	100,000	130,000	160,000	200,000	220,000
100	50,000	65,000	80,000	100,000	110,000
150	33,333	43,333	53,333	66,666	73,333
200	25,000	32,500	40,000	50,000	55,000
300	16,666	21,666	26,666	33,333	36,666
400	12,500	16,250	20,000	25,000	27,500
500	10,000	13,000	16,000	20,000	22,000
1,000	5,000	6,500	8,000	10,000	11,000

The leakage allowed by this rule in the case of 100-volt lamps, using ·64 ampere of current per lamp, is

$$C=\frac{E}{R}=\frac{100\,v}{10{,}000{,}000\,\omega}=\frac{1}{100{,}000}\text{ ampere of leakage}$$

for every lamp in circuit. Each lamp, however, requires ·64 ampere; consequently the leakage = $\frac{1}{64000}$ part of the total current.

Or, the percentage leakage = $\frac{1}{640}$ = ·0016%.

Since by the above rule the dynamo requires to have the same insulation resistance as the lamp circuit, the insulation resistance of the *whole* circuit, including the dynamo, is half of that given by the formula and tables, and therefore the leakage is double, or $\frac{1}{32000}$ part of the total current, or $\frac{1}{320}$% = ·0032%.

* See Munro and Jamieson's "Pocket-Book of Electrical Rules and Tables," p. 179, at foot. This rules applies only to the dynamos, leads, and fittings for incandescent lamps arranged on the single parallel system. Should the lamps be arranged in parallels, with two or three or more lamps in series in each parallel, they count as but one for each parallel.

Phœnix Fire Office Rules.—In May, 1888, in the thirteenth edition of the Phœnix Fire Office Rules, Mr. Heaphy recommends that "in any electric light installation in which the current is continuous, and has an electromotive force of 200 volts or under, the insulation resistance over the whole circuit inside any buildings should never run below 10,000 ohms. . . . With currents of 1,000 volts the insulation resistance should never drop below 50,000 ohms, no matter how wet the weather may be. For alternate currents the minimum insulation resistance should be twice the above number of ohms respectively."

In November, 1888, in the fourteenth edition, Mr. Heaphy is more precise, and he has added a table based upon similar proportions to the writer's rule.* His Rule No. 27 reads as follows: "In any electric light installation in which the current is continuous, and has an E.M.F. of 200 volts or under, the insulation resistance over the whole installation should not be below the following:

"Installations of	25 lights	......	500,000 ohms.
,,	50 ,,	......	250,000 ,,
,,	100 ,,	......	125,000 ,,
,,	500 ,,	......	25,000 ,,
,,	1,000 ,,	......	12,500 ,,

When the lights are proportionate between the above numbers, then the insulation resistance should be correspondingly proportionate. The insulation resistance of separate circuits of the installation should also be taken, and should be in accordance with the above table. For alternate currents the minimum insulation resistance should be twice the above number of ohms respectively."

Objections to Phœnix Rule.—The following objections may be offered in regard to this last rule:

1. It ties down a contractor to one and the same insulation resistance whether the E.M.F. of the installation lies anywhere below 200 volts. Surely a 50-volt installation requires but half the insulation resistance of a 100 volt one, and but one-fourth that of one with 200 volts.
2. It is somewhat doubtful (owing to a previous note to Rule No. 20) whether the words "over the whole installation" include the dynamo as well as all the wires, fittings, and lamps.
3. No distinction is made between cir cuits with one, or two, or more lamps in each parallel.
4. Arc lamps of 2,000 c.p. or more in parallel, and large incandescent lamps of 500 c.p. or more, which require strong currents, come under the same general words, "any electric light installation in which the current is continuous," just as much as small incandescent lamps of, say, 5 c.p., which require only a fraction of an ampere.

A question naturally arises here for discussion, Should not the insulation resistance in such extreme cases bear some definite proportion to the current?

Westminster Fire Office Rule.—In 1888 the Westminster Fire Office issued a set of rules for guiding their officers in regard to electric light installations, in which they demand that the insulation resistance shall in no case be less than 150,000,000 ohms per mile! Surely they have been blindly making extracts from a submarine cable specification! No contractor could be expected, under ordinary circumstances, to complete his work (including dynamo and fittings) to such a high standard.

M. Picou's Rule.—On November 7, 1888, M. Picou communicated his rule to the International Society of Electricians, Paris.† Using the same symbols as in the writer's rule, it is—

$$R_I = k\frac{E}{C},$$

where R_I = the total insulation resistance of the circuit in ohms;
k = a constant (500) found by experiments with short lengths of wire covered with three layers of cotton wound in reverse layers and pressed between metal plates;
E = maximum E.M.F. of the generator in volts;
C = total current generated or passing through circuits in amperes;
$\frac{E}{C}$ = the resistance in ohms of the whole circuit when the installation is in full working order.

The differences between M. Picou's rule and the writer's lie in the different values given to the constant, k, and in the substitution by M. Picou of the total current, C, for the total number of lamps, N_L, in the writer's rule. There is no doubt an advantage in thus substituting C for N_L, since the constant, k, thereby expresses directly the number of times the insulation resistance is of the apparent working resistance, $\frac{E}{C}$. And its reciprocal, the proportion which the leakage current bears to the total current. For, let c = the leakage current, and adopting the same symbols as above for the other terms, then

$$c = \frac{E}{R_I} = \frac{E}{k\frac{E}{C}} = \frac{C}{k},$$

$$\therefore \frac{1}{k} = \frac{c}{C} = \frac{\text{leakage current}}{\text{total current.}}.$$

* It will be observed that the above table corresponds identically with the writer's rule for an E.M.F. of 125 volts; *e.g.*, take 100 lamps; then

$$R_I = k\frac{E}{N_L} = 100{,}000\ \omega\frac{125\ v}{100\ L} = 125{,}000 \text{ ohms};$$

and so on in proportion to the number of lamps.—A. J

† See *Electrical Review*, Nov. 23, 1888.

We, however, consider that M. Picou's constant, 500, is by far too low to ensure good and lasting work. By it a circuit of 1,000 lamps of 16 c.p. each, requiring 100 volts and ·64 ampere each, the total insulation resistance of the circuit would only need to be 78·1 ohms, instead of 10,000 ohms by the author's rule (or 5,000 ohms if the dynamo be included).

The Society of Telegraph Engineers and Electricians' Last Rule.—In April, 1888, this society issued its second pamphlet of "Rules and Regulations for the Prevention of Fire Risks," and Rule 16 states that "the insulation of a system of distribution should be such that the greatest leakage from any conductor to earth (and in the case of parallel working from one conductor to the other when all branches are switched on, but lamps, motors, etc., removed) does not exceed $\frac{1}{5000}$ part of the total current intended for the supply of said lamps, motors, etc., the test being made at the usual working E.M.F." This rule includes all kinds and systems of electrical installations, and it is very neatly and concisely expressed. Some persons have, however, a difficulty in understanding how the $\frac{1}{5000}$ part of the total current is to be tested for or ascertained, and others do not see exactly how the test is to be applied to different parts of the circuits at the usual working E.M.F. *before* the installation is put into working order.

If the rule had also been put into the following form, with a table giving the insulation resistances required for a few of the more common E.M.F.'s and currents (or number of lamps), it would no doubt have recommended itself more readily to those unaccustomed to deal with the form of expression used in the rule. Using the same symbols as before, we have—

$$\frac{1}{5{,}000}C = c = \frac{E}{R_I},$$

$$\therefore R_I = 5{,}000\frac{E}{C} = k\frac{E}{C},$$

which is the form of expression used before, and most easily applied. This gives a constant ten times as great as M. Picou's, and about one-tenth that of the writer's rule. Which of these constants is most in accordance with good practice?

Table of Insulation Resistances required by the Society of Telegraph Engineers and Electricians' Last Rule—viz., the leakage of any part of an installation not to exceed* $\frac{1}{5000}$ *of total current supplying that part; or,* R_I = 5,000 E/C.

Number of amperes in circuit.	For 50-volt lamps.	For 65-volt lamps.	For 80-volt lamps.	For 100-volt lamps.	For 110-volt lamps.
	Ohms.	Ohms.	Ohms.	Ohms.	Ohms.
1	250,000	325,000	400,000	500,000	550,000
10	25,000	32,500	40,000	50,000	55,000
20	12,500	16,250	20,000	25,000	27,500
40	6,250	8,125	10,000	12,500	13,750
50	5,000	6,500	8,000	10,000	11,000
100	2,500	3,250	4,000	5,000	5,500
150	1,666	2,166	2,666	3,333	3,666
200	1,250	1,625	2,000	2,500	2,750
300	833	1,083	1,333	1,666	1,833
400	625	812	1,000	1,250	1,375
500	500	650	800	1,000	1,100
1,000	250	325	400	500	550

* If we include the dynamo as well as the whole of the lamps, motors, etc., will the insulation resistance of the whole installation be half the above figures?

Different Tests.—The ordinary Wheatstone bridge test is the handiest and easiest method of ascertaining the actual resistance in ohms of the conductors as well as of the insulation resistance. Should the insulation, however, be too high for the battery power and the galvanometer, then the direct deflection substitution method may be adopted. These tests are so fully described in every book on testing, and are, besides, so well known, that there is no need to explain them here. The battery power need only be a few Leclanché cells (10 or 12 at the most) if the galvanometer used is of the sensitive-mirror Thomson type.

When the installation has been completed, then the whole of the results may be obtained by means of ordinary ampere and volt meters.

First, join up the circuit as follows, in Fig. 3:

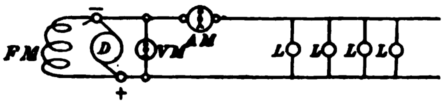

Fig. 3.

Work the installation at its normal power and observe the total current, C, by the ampere-meter, A M, and the difference of potential, E, by the voltmeter, V M. This gives us $\frac{E}{C}$.

Second, join up the voltmeter as in Fig. 4, with one side to earth having previously ascertained its resistance, r, ohms. Also note, C, on the ampere-meter, and see that it is the same as before.

If any leakage to earth exists in the dynamo or in any part of the circuit, a deflection on the voltmeter, V M, will be produced corresponding to the leakage current, c, passing through it, and is represented by, e, volts difference of potential between its terminals,

Digitized by Google

Then, $\frac{e}{r} = c$, the total leakage current.

But $\frac{C}{c} = k$, the actual constant or coefficient of the insulation resistance of the system.

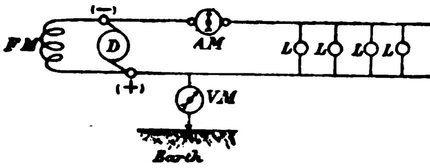

FIG. 4.

Then, if this value is greater than k, our standard constant, the installation may be considered all right as far as insulation resistance is concerned. Of course this does not inform us if any leakage is taking place between the forward and the return system of wires, or between the shunt and the series windings of the dynamo.

To ascertain the former of these, disconnect all the lamps and insert the voltmeter first in the forward lead, and secondly in the return lead, as in Fig. 5, and note if we get any leakage current, c, when the

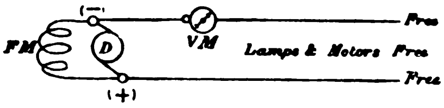

FIG. 5.

dynamo is run at its normal speed. In regard to leakage between the shunt and series windings of the dynamo-magnets, recourse must be had to the Wheatstone bridge test.*

No doubt some of the members will suggest other practical tests, as well as give their experiences of how the insulation resistance of installations with which they happen to be intimately acquainted compare with the various rules herein mentioned, as well as how they stood the test of time—wear and tear of everyday work. What is chiefly wanted is to ascertain the minimum standard of insulation resistance compatible with good honest work and ordinary careful usage.

P.S.—Since correcting the proof-sheets of this paper the writer thought that it might be interesting and instructive if he obtained the insulation resistance of an installation that had been working for some years, because members and others might say that some of the foregoing rules were all very well for *new* work, but were quite inapplicable to *old* work. He accordingly went to-day (January 16, 1889) to Messrs. Graham's large East India offices and warehouses in Cathedral-street, Glasgow, with his testing apparatus, and took careful tests of the insulation resistance of the whole circuit, with the results shown in the following table:

Original date of fitting up installation	1881 82
Date on which most of the wiring was renewed	1883
Date of test (day wet—Glasgow weather)	Jan. 16, 1889
Total number of lamps in circuit of 16 c.p. each	281
E.M.F. at brushes of dynamo, in *volts*	108
Current total from dynamo for all lamps in *amperes* (*about*)	160
Insulation resistance of dynamo-armature and magnet-coils alone, in *ohms*	40,000
Insulation resistance of the *whole* circuit, including the dynamo, *all* leads, switches, cut-outs, and lamps in *ohms*	21,400
Insulation resistance to pass Jamieson's rule, including *dynamo* as well as the *whole* lamp circuit, in *ohms*	19,217
Insulation resistance to pass Society of Telegraph Engineers and Electricians' rule (if their constant includes *dynamo* as well as the *whole* lamp circuit, in *ohms*	3,375

This old installation (the oldest large incandescent light one in Scotland), which has been in full daily working order for over five years (since the wiring was renewed) when tested, without warning or any special preparation, and on a very damp day, gave a better insulation resistance than that demanded by the writer's rule, and over six times that required by the Society of Telegraph Engineers' rule (taking it in its broadest sense).

It is worth mentioning that the president, Sir William Thomson, has taken a special interest in this installation from its very commencement. In 1881, when so few electricians knew practically how incandescent lighting should be carried out, and when the Messrs. Graham were erecting their large new premises, they consulted Sir William Thomson as to whether or not they could reply upon the electric light. Upon his recommendation they fitted their premises throughout with the electric light, without introducing gas-burners into any of their offices and warehouses. The actual carrying out of the present wiring of the building has been entirely done by one of the writer's students, who has had charge of the installation for the last six years. The Messrs. Graham have been so pleased with the care and attention which he displayed that they have sent him to their new premises which they are at present erecting in Oporto, Portugal, to superintend the building and put up an electric light installation there.

The dynamo which the writer tested, and which gave a total insulation resistance of 40,000 ω, against framing and dead earth, is a Manchester shunt-wound machine by Messrs. Mather and Platt, put down about two years ago to replace the direct lighting of the building by three of the oldest shunt-wound dynamos in existence. These three machines are now employed in charging accumulators which serve to feed the lamps used in the darker parts of the building during the daytime. The writer tested the insulation resistance of one of these old machines, and found that it gave for armature and shunt coils just over 10,000 ohms, as against the frame of the machine.

In addition to the above tests, that indicated by Fig. 4 was applied, and no perceptible leakage current was observable on the voltmeter, even although the sensitive coil, which reads to less than a volt, was inserted.

The writer might give the results of several new installations which have surpassed his rule, and which therefore far exceeded the demands of the society's rule. He therefore thinks that the constant of the latter might be raised from 5,000 to 10,000 with perfect fairness, and with beneficial results to the electric lighting industry as a whole.

* For other tests when the installation is at work, see Munro and Jamieson's "Electrical Rules and Tables," 5th edition, pp. 215, 216.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the week ended January 18 amounted to £5,077.

Western and Brazilian Telegraph Company.—The traffic receipts for the past week, after deducting a fifth of the gross earnings payable to the London Platino-Brazilian Telegraph Company, were £4,195.

West India and Panama Telegraph Company.—The receipts of this Company for the half-month ended December 31 were £2,352, against £2,805. The September receipts, estimated at £4,515, realised £4,540. The receipts for the half-month ended January 15 were £2,381, against £2,676.

Cuba Submarine Telegraph Company, Limited.—The Directors of this Company, after providing for the dividend on the preference shares, and placing £4,000 to the reserve fund, recommend a dividend on the ordinary shares at the rate of 9 per cent. per annum, tax free, leaving £1,308 to be carried forward.

Anglo-American Telegraph Company, Limited.—This Company recommend a balance dividend of 15s. per cent. on the ordinary and one of 30s. per cent. on the preferred stock for the year ending the 31st of December, both payable on the 2nd of February, less income tax, to the stockholders registered on the 14th inst. After paying the foregoing, there will be an estimated balance of £1,325 to be carried forward. The above dividends together with those already paid will amount to £1. 12s. 6d. per cent. on the ordinary and £3. 5s. per cent. on the preferred stock for the year 1888.

Eastern Telegraph Company, Limited.—The report of this Company for the half-year ended September 30 states that the revenue amounted to £310,104, from which are deducted £83,332 for the ordinary expenses and £43,075 for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing for income tax there remains a balance which, added to £884 brought forward, makes a total of £180,355. Interest on debentures and debenture stock took £28,264, the dividend on preference shares £20,474, and two interim dividends of 1¼ per cent. each on the ordinary shares £95,000, £36,616 being carried forward.

Direct United States Cable Company, Limited.—This Company in their report for the six months ended December 31, state that the revenue (still subject to revision on settlement with the French Company), after deducting out-payments, amounted to £34,188, against £23,003 (after similar deductions) for the corresponding period of 1887, the difference of £11,185 in favour of the half-year under review being due to the increased tariff in force since the 1st of September. The working and other expenses for the same period, including income tax, amounted to £16,475, leaving a balance of £17,712 as the net profit. Interim dividends of 2s. for the quarter ended September 30, and of 3s. 6d. for the quarter ended December 31, together amounting to £16,695, have been declared. The tariff was on the 1st of September raised to 1s. per word, by agreement between the associated companies (including the French Company) and the Commercial Cable Company. The result of the altered rates so far has been to reduce the volume of the traffic, but the receipts have, it is stated, been fully augmented.

Bell's Asbestos Company, Limited.—The report of the Directors for the year ended 31st December, to be presented to the shareholders at the first ordinary general meeting to be held at Cannon-street Hotel, on Wednesday next, states that the net profit from the ordinary trading of the Company after making all needful deductions, including depreciation of machinery and bad debts, amounted to £23,429. 6s. 5d., and the net profit from the Company's Asbestos Estates in Canada to £10,992. 0s. 4d.; a total of £34,421. 6s. 9d. From this the Directors write off the whole of the preliminary expenses account amounting to £836. 14s. 7d., and under the terms of the articles of association they place to reserve fund, £5,000; a total of £5,836. 14s. 7d., leaving for appropriation, £28,584. 12s. 2d. Out of this, the Directors recommend the payment on the 4th February proximo of a dividend of 15s. per share, free of income tax, which, with the interim dividend paid in July last, makes a total distribution of 22½ per cent. for the year, and the payment of the bonus, £2,250, to the Managing Director and Directors, in terms of the articles of association, carrying forward a balance of £3,834. 12s. 2d.

German Union Telegraph and Trust Company.—An extraordinary general meeting of the German Union Telegraph and Trust

Digitized by Google

Company, Limited, was held on Tuesday, the 22nd inst., at Winchester-house, Old Broad-street, Sir James Anderson in the chair, to consider special resolutions requiring the Company to be wound up voluntarily and appointing liquidators (in accordance with the arrangements under which the Imperial German Government would take over the cables and property of the German Union Telegraph Company of Berlin). The Chairman stated that the first payment made by the liquidators of the Berlin Company would enable the liquidators of this Company to return to the shareholders about £7. 7s. 6d. per £10 share. They expected to be able to make their first payment in the first week of February; and they hoped to complete the winding up of the Company and to make a final payment to the shareholders early in May. They hoped to be able to make a total return to the shareholders of very nearly par. He concluded by moving a resolution authorising the winding up of the Company. Mr. H. G. Erichsen seconded the motion, which was adopted; and a further resolution was afterwards passed appointing Sir James Anderson and Mr. William Payton liquidators of the Company. In answer to a question, the Chairman added that the cable was now being worked by the German Company.

NEW COMPANIES REGISTERED.

Miners' Lamp Electric Lighting Company, Limited.—Registered by Waterlow Brothers and Layton, Limited, 24 Birchin-lane, London, E.C. Capital £3,000, divided into 600 shares of £5 each. Object: to purchase or otherwise acquire a certain invention and letters patent for lighting miners' safety lamps and wicks, and to carry on the business of a safety lamp manufacturing company and electric light company in all its branches.

Maxim-Weston Electric Company, Limited. — Registered by Gresham and Davis, 12, Old Jewry, London, E.C. Capital £75,000, divided into 500,000 shares of 3s. each. Object: to acquire and undertake the property and liabilities of the Maxim-Weston Electric Company, Limited (in liquidation); to light streets, thoroughfares, public places, public or private buildings, manufactories, mines, houses, ships, etc. The first subscribers are:

	Shares.
A. Cousens, 28, Westbourne-park-villas	1
J. R. McVeagh, 1, Upper High Lever-road, W.	1
W. H. White, Stock Exchange, E.C.	1
G. H. Hildyard, Great Dover-street, Borough, S.E.	1
J. G. Couchman, Southwood, Eltham-road, Lee	1
A. R. Ramsay, 2 Metal Exchange-buildings, London, E.C.	1
B. Whitworth, jun., 2, Metal Exchange-buildings, London, E.C.	1

The first Directors shall be John Marks, 113, Great Russell-street, W.C.; James Gunton Couchman, Southwood, Eltham-road, Lee; George Herbert Hildyard, 34, Wickham-road, St. John's, S.E.; John Matthew Klenck, 42, Bishopsgate-street, E.C.; and Louis Swaby, 23, Churchfield-road, Ealing. Each Director shall hold at least 250 shares in the capital of the Company. The remuneration to the Directors shall be the sum of £1,100 per annum, to be divided amongst them as they may determine.

Newcastle and District Electric Lighting Company, Limited. Registered by E. Flux and Leadbitter, 144, Leadenhall-street, London, E.C. Capital £50,000, divided into 5,000 shares of £10 each. Object: to act as undertakers for the supply of electricity for lighting and other purposes, whether public or private, in the city of Newcastle-upon-Tyne or anywhere else in the United Kingdom, and to do all or any such acts as may be necessary to promote, support and sustain any Acts, provisional orders, licenses or other authorities which may be required or be deemed necessary to benefit the Company, or for the more properly carrying out of all or any of the objects of the Company. The first subscribers are:

	Shares.
The Hon. C. A. Parsons, Elveston Hall, Ryton-on-Tyne	1
Sir B. C. Browne, West Acres, Newcastle	1
J. D. Millbourn, West Jesmond House, Newcastle	1
J. B. Simpson, Hedgefield House, Ryton-on-Tyne	1
H. C. Harvey, St. John's Chambers, Newcastle-upon-Tyne	1
Rt. Hon. Earl Crawford, 2, Cavendish-square, London, W.	1
A. F. Wade, 9, Albert-mansions, Victoria-street, London, S.W.	1
W. M. Angus, St. John's Works, Newcastle-upon-Tyne	1
C. W. Spencer, Mewburn Steel Works, Newcastle-upon-Tyne	1

Registered without articles of association, and therefore the clauses of the first schedule of the Companies Act, 1862, will apply.

PROVISIONAL PATENTS, 1889.

JANUARY 14.

656. **Measuring the quantity of a direct or alternating current of electricity.** William Henry Dines and Leonard Wilson Gatward, Bancroft, Hitchin.

706. **Electric accumulators.** Michael Radcliffe Ward, 9, Warwick-street, Regent-street, London, W.

JANUARY 15.

731. **Improvements in conduits for cable and electric railways.** William John Brewer, 33, Broadway, New York, U.S.A.

733. **Improvements in apparatus for controlling the speed of engines employed for driving dynamos, so as to ensure steady and equable lights.** Richard Wilby, Commercial-street, Halifax.

746. **Improvements in and relating to electric secondary batteries or accumulators.** Orazio Lugo, 45, Southampton-buildings, London, W.C. (Complete specification.)

757. **Improvements in and relating to a system of suspended bare wires, travelling connections between the said wires and the motor and switches, &c., in and for electric railways.** Charles Joseph Van Depoele, 77, Chancery-lane, London, W.C. (Complete specification.) (Date applied for under Section 103 of the Patents, &c., Act, 1883, 9th August, 1888, being date of application in the United States.)

759. **Improvements in switches for electric railways.** Clark Homer Wells, 77, Chancery-lane, London, W.C. (Complete specification.)

JANUARY 16.

811. **Improvements in the mode of application of magnetism and electricity for medical purposes.** John Garton, Willow Bank, Newton-le-Willows, Lancashire.

813. **Separation of aluminium and its alloys from its fluorides by electric or by chemical metallurgic process.** Wilhelm Diehl, 89, Chancery-lane, London, W.C.

JANUARY 17.

859. **Improvements in telephonic apparatus.** Herbert Feilden Jackson and Daniel Sinclair, 62, St. Vincent-street, Glasgow.

877. **A magnetic and sight compass.** Willoughby Verner, Charles-street, London, S.W.

895. **An improvement in or connected with electrical connections for burglar alarms.** John Crisp Fuller and George Fuller, 33, Chancery-lane, London.

898. **Combined fire-alarm and telephone telegraph.** George C. Hale, Albert Barrett, and Joseph Zeutner, 45, Southampton-buildings, London. (Complete specification.) (Date applied for under Section 103 of the Patents, &c., Act, 1883, 27th June, 1888, being date of application in the United States.)

915. **Improvements in electric switches.** Sebastian Ziani de Ferranti, 45, Southampton-buildings, London, W.C.

JANUARY 19.

983. **Improved electric time alarm and indicator.** C. Adams-Randall, 15, Montpelier-square, Brompton, London.

997. **Improvements in secondary or storage batteries.** Thomas Cuttriss, 72, New Briggate, Leeds.

1,006. **Improvements in electrical pole-changers.** Percy Coote, 40, Preston-road, Brighton.

1,018. **An improved method and apparatus for facilitating the working of telegraph instruments.** George Edward Adler, 98, North End, Croydon, Surrey, S.E.

1,031. **Improvements in dynamo-electric machines.** John Wm. King, 13, St. John's-square, Clerkenwell, London, E.C.

1,038. **Improvements in and relating to electric lamps for signalling purposes.** John Price Rees, 45, Southampton-buildings, London.

1,047. **Improvements in propelling vehicles by means of electric motors.** Michael Radcliffe Ward, 24, Southampton-buildings, London, W.C.

SPECIFICATIONS PUBLISHED.

NOTES.

Kiel.—The establishment of a central station for Kiel is now being discussed, to start at first with 500 incandescent lamps.

Southwark.—St. Saviour's, Southwark, offers no opposition to electric lighting schemes, but insists that all wires should be laid underground.

A New Electrical Journal.—The *Gas World* is becoming more and more electrical: about seven columns out of thirty-two are devoted to our subjects.

Wallsend.—The Wallsend Local Board consider themselves treated contemptuously by the gas company. They are considering the question of electric lighting.

The Whitehall Installation.—The battery of accumulators are now down at the Whitehall central station. The Hotel Metropole and the Grand Hotel, Charing Cross, are both to be connected to this station.

Holborn.—At the last meeting of the Holborn Vestry, a meeting was called to be held on Monday, February 18, to consider the applications of the London Electric Supply Corporation and the Metropolitan Electric Supply Company.

Electrical Tree Cutter.—Messrs. Ganz and Co. have constructed an electrical tree cutter for use in the forests of Galicia. This consists of a drill driven by electricity, by means of which a series of holes close together can be made through the trunk.

Metropolitan Company's Stations.—The new Sardinia-street central station—Westinghouse system, 25,000 lights—is to be ready in March. The Waterloo Bridge station—Kapp system, by Messrs. Johnson and Phillips—is to be ready about next June or July.

Electric Sugar.—It has been said that Friend, the inventor of electric sugar, is probably still alive, and ready to commit further frauds with the proceeds of this one. There need be no fear. Dr. Crosby, who attended his last illness, certifies to his having drunk himself to death some time ago.

Lighting of the Hotel de Ville.—On the eve of the Paris election, M. Jacques, who was the opponent to Boulanger, was entertained at a public ball at the Hotel de Ville, Paris, when 12,000 guests were present, and the whole suite of rooms was splendidly lighted up by electricity for the first time.

A New Use for the Compound Wire.—A French writer in *Cosmos* points out that in a compound-wound dynamo the machine can be used as a shunt or series dynamo only, and induced currents can be obtained from the disconnected wire; these "parasitical currents," he suggests, "might be used for lighting another circuit of lamps, or other purposes."

Court Theatre.—A gauge glass blew out the other night at the Court Theatre installation. No one knew what to do; the place was full of blinding steam, everyone flew, the cut-outs went, the engines raced, Messrs. Sharp and Kent were at their wits' end, when a young engineer happening to pass, seeing the steam and their sad plight, drew their fires for them and prevented a catastrophe.

A Meeting of Vestries.—The Wandsworth Board of Works has invited a meeting of delegates to secure combined action on the part of the local authorities of London with regard to electric lighting. We should certainly believe in some combined action of this kind, as to the interests of both parties, but should like delegates from the Electrical Section of the Chamber of Commerce also to be invited.

Electricity in Mines.—The Belgian Government have recently appointed a commission to enquire into the use of electricity in mines, and to settle upon regulations to be imposed in such cases for proper security of life. Blasting, lighting, transport, haulage, etc., will all occupy the attention of the commission, and it is hoped that the result of their experiments and deliberations will be to considerably extend the use of electricity in mining.

Board of Trade Unit.—The new Board of Trade unit suggested by the Electrical Section of the London Chamber of Commerce to be 10 times that of the old Board of Trade unit, has been definitely adopted by the Board of Trade. It is now, therefore, 10,000 watt-hours instead of 1,000 watt-hours as heretofore. The new unit is far more applicable commercially, and in view of this change we publish this week a comparison of the cost of lighting at various prices per new unit with that of gas per 1,000 cubic feet. This should prove useful to town councils and other authorities and firms intending to adopt the electric light and desiring to ascertain the comparative cost at any specified price per unit.

Prevention of Smoke.—The smoke nuisance is a point that central stations, comprising thousands of horsepower, in the centre of towns will have great difficulty with. A way of salvation for the gas companies has been pointed out in a paper on the prevention of smoke from boiler furnaces, lately read at the Institution of Engineers of Scotland. Methods adopted were described by Mr. Geo. C. Thomson, F.C.S., and particulars were given of the immense amount of sulphuric acid sent into the air, and loss occasioned in fuel, and damage to the parks, trees, houses, and vegetation. The proper way, Mr. Thomson suggested, was to convert the coal into gas first, distilling the sulphur, which would pay for the cost of gas making.

Dublin Central Lighting.—At a specially-convened meeting of the Dublin Municipal Council, held on Monday, it was all but unanimously resolved, there being only one dissentient, "to apply to the Board of Trade for a license to supply electric lighting for private purposes." It will be in the recollection of our readers that the Dublin Corporation have already acquired a license for public lighting, but on consideration it was found that the inducements to contractors would, of course, be much greater when private as well as public lighting could be undertaken. The Council have therefore very rightly decided to have their license amended, and it is hoped, before many months go by, active preparations will be on foot for the lighting by electricity of some of the principal streets of Dublin.

Business in Dublin.—The Dublin Alliance Gas Company have put down a new electric light installation during the past year, and are at present lighting some of the large business houses with both arcs and incandescents, and are offering inducements to new customers. There are also several other isolated installations working satisfactorily, such as those at Messrs. Guinness's Brewery Messrs. Findlaters, Mr. Talbot Powers, etc. Perhaps the most complete and successful installation at present working in Dublin is that at the offices of the *Irish Times*, which was erected about five years ago, and has been running

Digitized by Google

continuously ever since, under the superintendence of Messrs. J. K. Fahie and Son, electrical engineers, of Dublin.

Islington.—The Special Committee appointed to consider the applications of the London Electric Supply Corporation and the Metropolitan Supply Company, asking for the Vestry's assent to their applications for provisional orders, recommended that the clerk be directed to lodge objections to such provisional orders with the Board of Trade, in order to secure a *locus standi.* Mr. Price, who moved the adoption of the report, said that it was the unanimous wish of the committee that electric lighting should be brought into the parish if possible, but it was necessary that the Vestry should have a *locus standi* when the applications of the companies came before the Board of Trade. Mr. Friend seconded the adoption of the report, which was carried.

Electric Light and the Eyes.—The question as to whether those who have to do with powerful electric lights suffer in eyesight is discussed by Dr. G. M. Gould, of Philadelphia, who has written an interesting paper entitled "Is the Electric Light Injurious to the Eyes?" He concludes that the "light of the future" has not been proved to be injurious except in the case of those "who approached it very closely, gazed at it protractedly, and without protecting coloured spectacles." There is no justification for the popular prejudice against the use of the diffused light as an illuminant. The ocular injury occasionally incurred, due to the greater number of light waves, is characterised by temporary retinal paralysis, by blepharospasm, central scotomata, chromatopsia, etc., and is marked by intense photophobia, lacrymation, conjunctival congestion, etc. The attack usually lasts two or three days, the treatment being cocaine and atropine, and cold or hot compresses.

Another House-to-House Station.—The St. Martin's-in-the-Fields Vestry held a special meeting on January 24, to consider a motion to give consent under Rule 8 of the rules made by the Board of Trade with respect to applications for licenses and provisional orders under the Electric Lighting Acts 1882 and 1888, to the granting of a license by the Board of Trade, authorising the House-to-House Electric Supply Company, Limited, to erect, construct, and maintain a central station for electric lighting, with lines and works necessary to the same, and to supply electricity within the parish. The chairman thought that the Vestry should make up its mind how far they should go with respect to these companies. The Vestry had given consent to the application of two companies. The clerk said the Board of Trade were not disposed to grant licenses for large areas. Mr. Scott asked if the companies would be rated, and the clerk said they would. Mr. Wakefield moved that consent be not given, as he considered the information not sufficient. Mr. Prescott moved that consent be given, which was seconded, and carried.

Liverpool.—On Tuesday a deputation, representing the Liverpool Electric Supply Company, waited upon the Watch Committee of the City Council, and endeavoured to procure their assent to the provisional order which the company intend to seek during the forthcoming session of Parliament. The order, if obtained, will confer extended powers upon the company in the direction of lighting the streets of Liverpool by means of electricity, and it is of importance to the company that the Watch Committee should give their assent to the application which they propose to make to Parliament. This consent has hitherto been withheld, as the Watch Committee have failed to induce the company to agree to conditions which are deemed to be essential in the interests of the public. The object of yesterday's interview was to endeavour to arrange terms which might be mutually satisfactory; but we understand (says the *Liverpool Courier*) that, in spite of an unusually protracted consultation, it was found impossible to come to terms, and the practical result, therefore, is that the Watch Committee will refuse their assent to the company's application.

The Man with the Iron Pipe.—We do not wish in any way to liken Mr. Lowrie to disreputable personages, but the details which he has worked out of the House-to-House scheme remind us of the tale at the battle of Trafalgar-square. A man in that struggle of the unemployed was seen with apparently an innocent roll of paper in his hand, when it was noticed that he was dealing death and destruction around. What appeared to be simply paper was speedily found to be a piece of iron gas pipe pasted over with paper, and then the man with the iron pipe was found to be a formidable enemy. We think that the details of the underground boxes and iron piping for the electric distributing wires at West Brompton will carry more terror into the camp of the gas men than any other detail. We may prate of amperes and volts, and even talk of candle-power and so many thousands of incandescent lamps: these may be understood—more or less—and combatted in their own minds. But when it comes to iron pipes laid along streets, that is a point the gas world *can* understand and appreciate; and it does not need much imagination of electricity or lines of force to conceive of an extension of electric lighting by copper wires when iron pipes can be laid and connected up in all directions. Then, here's health to the man with the iron pipe!

Berly's Universal Electrical Directory.—We have received the 1889 edition of this well-known directory, and perhaps the best way to show its value and importance will be to describe its contents. In the first instance, we have a fairly complete list of modern books on electrical subjects, followed by a table relating to the new legal standard wire gauge. The principal part of the book comes next, and consists of an alphabetical list of persons engaged in the electrical and cognate industries, after which we have a list of the members of the Institution of Electrical Engineers, and of the Electrical Section of the London Chamber of Commerce. The British classified trades come next, and takes up a space of over one hundred and twenty pages. Further on we have the alphabetical and classified trades' sections devoted to American and continental electrical engineers. The extent of the whole work will be understood when we say it reaches to nearly four hundred and fifty pages. The great value of a directory depends upon its completeness and correctness, though absolute correctness is an impossibility. Upon this matter we cannot as yet speak from experience, though we hope to be able to do shortly. Meanwhile, we are assured that great efforts have been made to obtain accuracy, and when inaccuracies occur it is frequently the fault of the people themselves, who will not answer repeated enquiries. So far, however, as we can test from a cursory examination, the work is fairly accurate and complete.

Strand District.—At the meeting of the Strand Vestry, on Tuesday, Mr. Sinden moved the adoption of a report from the Roads Committee, recommending that this Vestry dissent from the granting of a provisional order by

Digitized by Google

the Board of Trade to the London Electric Supply Corporation, Limited, for the supply of electricity in this parish, under the Electric Lighting Acts; that this Vestry assent to the granting of a license by the Board of Trade to the House-to-House Electric Lighting Company, Limited, authorising that company to supply electricity within this parish. In answer to questions, Mr. Sinden said the committee objected to the first application because a provisional order would give the company privileges in the parish for forty-two years. The second company asked for a license which would only extend over seven years. A long discussion ensued, in the course of which Mr. Layman moved, as an amendment, that the matter be adjourned until the next meeting of the Vestry. This proposition having been negatived, Mr. Bacon moved a further amendment, suggesting a postponement of the matter, but the chairman declined to take any more motions for adjournment. Mr. Bacon: Then all I have to say is that you don't know your business as chairman. The first recommendation was adopted, but the consideration of the second recommendation was deferred until the next meeting of the Vestry, in order that the representatives of the House-to-House Company might be in attendance.

Amalgamated Zincs.—We have received from Mr. J. Beattie, jun., information relating to tests made by the electrician of one of the supply companies in Chicago, which reads as follows: "In 16 tests for E.M.F. four were made on a sal-ammoniac solution, six on a copper zincic sulphate solution, and six on a bichromate solution. Half of the tests were made with the ordinary commercial zincs and the other half being with the Beattie zinc. In the sal-ammoniac solution there was a rise of 2 per cent. in the E.M.F., in the sulphate solution a rise of $1\frac{8}{10}$ per cent., and in the bichromate a rise of $2\frac{2}{10}$ per cent. in E.M.F., showing that the Beattie zinc had an average of 2 per cent. the advantage of ordinary commercial zinc in point of E.M.F." As regards internal resistance, he says: "With the sal-ammoniac solution the internal resistance was reduced 22 per cent.; with the sulphate solution the internal resistance was reduced 32 per cent., 40 per cent. and $41\frac{1}{2}$ per cent.; in bichromate solution the internal resistance was reduced 11 per cent. . . . With a given amount of work done upon the outside circuit of the battery, as nearly as I could test, there was an average of 18 per cent. less zinc consumed by weight, and I should judge also that the care of the battery with this zinc would be much less. Short-circuiting was tried with the sal-ammoniac solution only, and shows satisfactory results owing to the fact that crystals do not form and the solution will recuperate somewhat more rapidly with these zincs than with the commercial zinc." This amalgamated zinc differs from the ordinary zinc in that, according to Mr. Beattie, it is amalgamated throughout its whole body, and not merely on its surface. Mr. Beattie also claims to have discovered a better carbon for battery work. It is made from salt hay and salt meadow grass. This is carbonised, pulverised, and moulded as required, and it is claimed has greater conductivity than the ordinary gas rebut carbon.

Storage Battery Patents.—As we gave the information relating to the Julien Company's patents, it is but just we should give the following from the Electrical Accumulator Company, Limited: "A public statement from the Julien Company has appeared, which it is made to appear that the application of the Electrical Accumulator Company for a certain patent has been refused by the United States Patent Office. Such a statement is not true; on the contrary, the Commissioner of Patents, Washington, has just rendered a decision sustaining the claims of John S. Sellon as the inventor of an inoxidisable alloy support plate, and Mr. Sellon's patent has been passed to issue, and will shortly appear on the patent records duly assigned to the Electrical Accumulator Company. The application of Sellon was founded upon the specification of his English patent No. 3,987, dated September 15th, 1881. This British patent of Sellon's is the first publication to describe the use of a plate of lead and antimony, or an alloy of two metals, either with or without the use and application of an amalgam as a support for the active material in a battery of the Faure type. Immediately following the decision of the commissioner above referred to, a second application of Sellon's claiming an alloy of two or more metals and an amalgam, was placed in interference with Julien's patent. It will thus be seen that litigation up to this date in the Patent Office has resulted in the substitution of Sellon's second application for the first application which was placed in interference on the allowance or passing of Sellon's first application to issue. The issue of this patent in the United States will enable the assignee of Sellon, the Electrical Accumulator Company, to control the manufacture, use and sale of secondary batteries employing lead and antimony in the composition of the support plates, whether mercury to form an amalgam be present or not, and suits will be instituted in the courts for the recovery of damages at once."

St. George's, Hanover-square.—At a meeting of the St. George's, Hanover-square, Vestry on Thursday, January 24, Mr. H. H. Seymour presiding, the Electric Lighting Committee submitted a long report, which showed that the following companies were applying for provisional orders to supply the parish with the electric light: The London Electric Supply Corporation, Limited; Metropolitan Electric Supply Company, Limited; Westminster Electric Supply Company, Limited; and the Chelsea Electric Supply Company, Limited. The report recommended that the application of the latter company should be refused, and, if necessary, opposed before the Board of Trade; that the matter be referred back to the committee for negotiation with the three other companies with a view to altering their drafts in certain particulars; and that the Vestry authorise the committee to instruct Messrs. Caprons and Co., solicitors, to oppose all or any of the four schemes, as might appear expedient. The suggested alterations included binding the companies to complete any works within eighteen months from the date of the order instead of two years; that, providing a company fail to perform its obligations to light any place, a money penalty should be inflicted rather than a revocation of its order as to that particular place; that the quality of the lighting should be subject to the inspection and superintendence of the County Council, and that deposits of £500 should be made to answer damages by work which might be begun and never continued. Such a deposit the committee would not ask for in the case of the London Electric Supply Corporation, because it had valuable work in that parish and elsewhere, and was thoroughly responsible. The Metropolitan and Westminster companies were not in any such position, and it was thought prudent to require a deposit from them. The adoption of the report and recommendations was moved by Lord Hobhouse, seconded by Sir William Farrer, and agreed to unanimously. The committee sat for about three months on this subject,

Gilchrist Science Lectures.—A lecture, under the auspices of the Mayor and Corporation of Norwich, illustrated by the oxy-hydrogen light and numerous experiments, was delivered in St. Andrew's Hall, Norwich, last Monday, to an extremely crowded audience, on "The Position and Prospects of Electric Lighting," by Mr. W. Lant Carpenter. The syllabus of the lecture was as follows: Meaning of the term Electric Current; Methods of producing it for lighting purposes, (*a*) by "Primary Batteries," *i.e.*, by chemical action, (*b*) by dynamo machines, which, by converting Mechanical into Electrical Energy, produce Electricity at the least possible cost; Explanation of the principle of the Dynamo, and of some of its chief types; its great perfection as a machine, compared, for example, with the Steam-engine; Secondary (or storage) batteries or accumulators, their theory and construction; in any system of Gas Lighting, production, storage, distribution, and consumption have to be considered; the same is the case with Electric Lighting; Modes of distributing currents at high and low Electric pressure; their relative advantages, etc.; Continuous and alternating currents; Transformers for changing currents distributed at high potential to those of low potential suitable for use, and free from danger; Electric Meters; Source of the light in Electric lamps; the transformation of Electrical energy into heat energy, owing to the resistance opposed to the passage of the current; Arc and incandescent (or glow) lamps—the uses for which each is best adapted; the light being produced without combustion, but little heat, and no noxious products are formed; Comparison of cost between Electric and other methods of lighting; Present position of the industry in England, the Continent, and America; Central station lighting; Private installations; Ship lighting, especially in the Suez Canal; Theatre lighting; Electric light in coal mines, powder magazines, etc.; Effect of recent judicial decisions, and of legislation upon the industry; Conclusion. The lecturer was assisted in the experiments by Messrs. Laurence, Paris, and Scott, electrical engineers, of Norwich. The same lecture will be delivered this week, for the Gilchrist Trust, in Hinckley, Wolverhampton, Wrexham, and Burslem.

Trial of an Electric Car Brake.—The Widdifield and Bowman electric car brake, says the *Scientific American*, was subjected to a series of tests on January 10, a train of fifteen freight cars being used for the trial, which took place upon the Lehigh Valley Railroad between Metuchen and Easton. A drum about six inches in diameter is cast around the axle of a pair of car-wheels. The drum is composed of Babbitt metal, with paper discs embedded in it. A small friction-wheel is drawn against this by the action of a magnet excited by the electric current. Only an instant is required to do this, as a ratchet bar and pawl are provided to hold the wheel in place when forced against the friction-drum. At once the wheel begins to rotate, and in doing so winds a chain around its axle. This draws a larger wheel, with, of course, greatly increased power against the friction-drum. It rotates, and winds the brake chain directly around its axle, thus putting on the brake. To release the brakes, another current is sent, which operates a second magnet that unlocks the pawl and ratchet, the friction wheels fall back, and the brakes cease to act upon the periphery of the wheel. Two storage batteries of 10 or 12 cells each are carried, one on the engine and the other in the rear car. With each battery is a switchboard and connections. Thus, if the train breaks in the middle, each half is provided with a full brake equipment. An automatic attachment is so arranged that if the train is cut in two by design or accident, the brakes are at once put on. But each switchboard contains a releasing switch, so that if the cut-off occurs in a place where stoppage would be dangerous, the brakes can be released on either or both portions of the train. Attachments are also provided so that brakes can be put on from the roof. The main battery is kept on open circuit, and is only closed for an instant, when the brakes are to be actuated. One or two cells are kept on closed circuit to operate the automatic part. Thus, there is a very slight waste of electricity. In all the trials, which included emergency and service stops, cutting off portions of the train, etc., the mechanism worked perfectly, and it seemed well adapted for its ends. Its cost was stated to be but a small fraction of that of an air-brake equipment. The trials were witnessed by a number of representative railroad engineers and journalists.

Electric Traction on the Metropolitan.—At the meeting of the Metropolitan Railway Company the directors refer in their report to the proposed working of their railway trains by electricity. They regret that the Electric Traction Company have not yet been able to complete their arrangements for the experimental working by an electric power locomotive on a section of their railway. The following letter from the chairman of the Traction Company has been received: "The Electric Traction Company, Limited, New Broad-street House, London, E.C., 31st December, 1888: The Board of Directors, Metropolitan Railway, Gentlemen,—In reply to your enquiry respecting the progress of the electric locomotive for your company, I have to say that the difficulties which were spoken of in your last report, which principally concerned the working of the vacuum brake without the use of steam, though intractable for a considerable time, have now been overcome. The whole matter is in active progress, and has made considerable advance since the last report. The Electric Traction Company wish it to be explained that an erroneous belief appears to be entertained that they propose to suggest traction by means of accumulators for ultimate use on the Metropolitan line. This is not the case. The use of accumulators is for a temporary service only, and is rendered necessary by circumstances connected with the traffic, which will disappear when electric traction is adopted on the Underground Railway.—I am, gentlemen, yours faithfully, (signed) Bury, chairman, Electric Traction Company." The brake difficulty was a very practical one. The working of the vacuum brake without steam, can, of course, be accomplished when sufficient attention to the mechanical details has been given. We might suggest a more radical course—the entire abandonment of air brakes for electrical brakes. The question of electrical brakes has been before us for some time, but no practical tests have been forthcoming. We are fortunately able, however, at this very moment to refer to practical tests of an electrical air brake, which will be found in another note, and we invite the attention of Lord Bury and the directors of the Metropolitan to this new departure, which may prove extremely important, especially when electric locomotives are adopted. The whole of the travelling public of London is anxiously awaiting the result of the trials of electric locomotives on the Underground Railway, and they will bless the day when electrical and railway engineering combine to add so largely to their comfort.

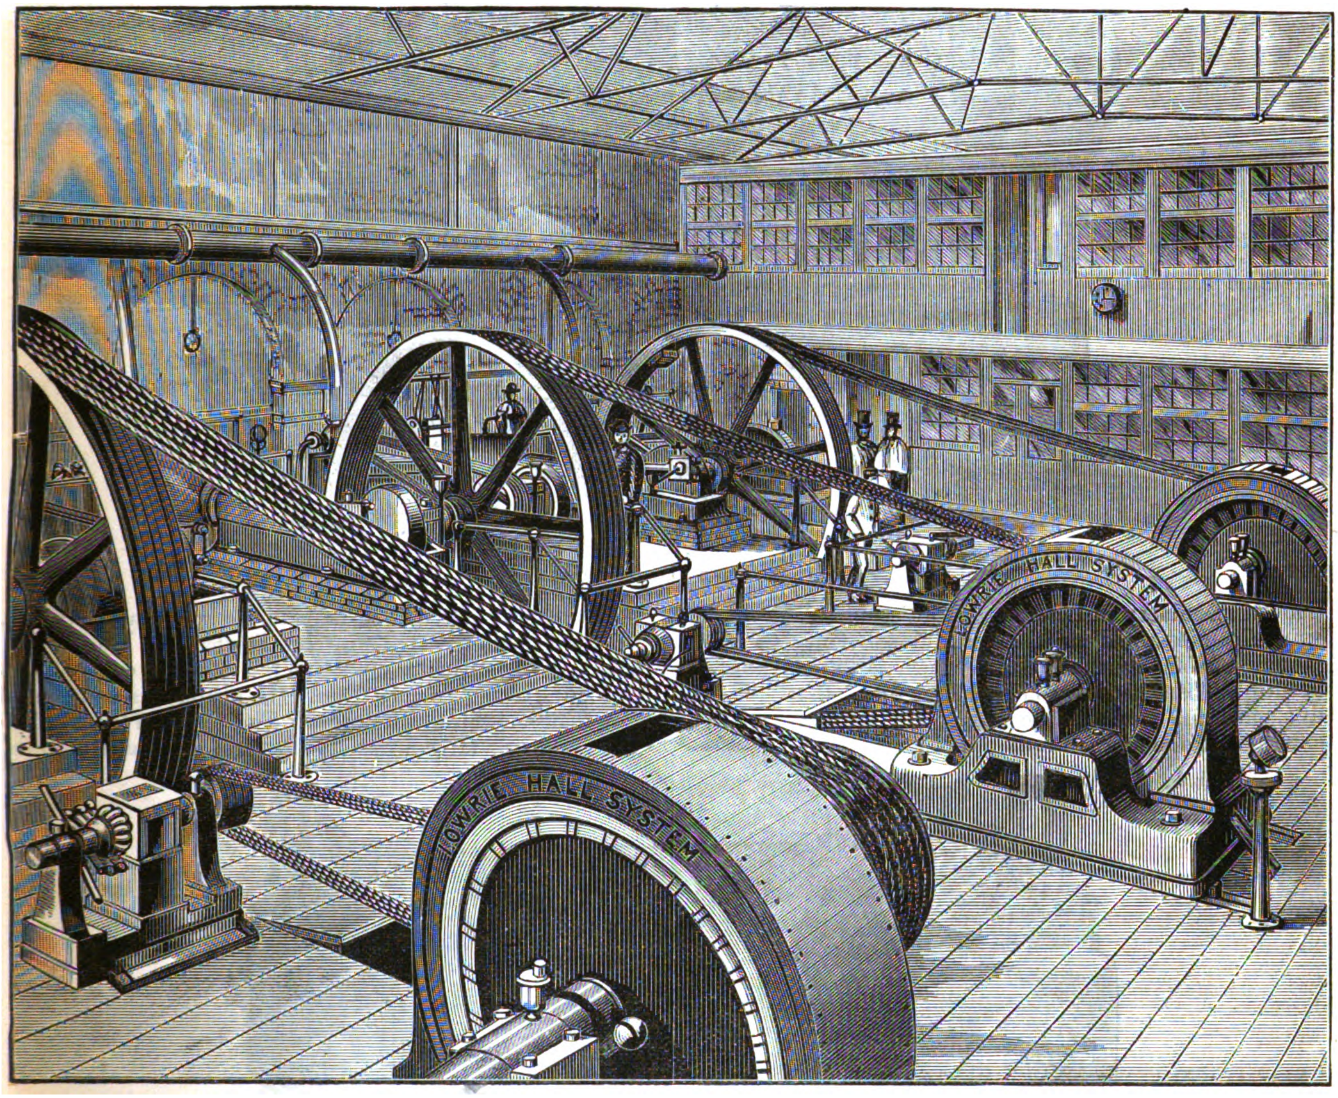
THE HOUSE-TO-HOUSE COMPANY'S STATION AT WEST BROMPTON.

On Thursday week the new central electric light station of the House-to-House Electric Supply Company, Limited, at West Brompton was thrown open for inspection. The inauguration of the station was made the occasion of a very active state of jubilation, explanation, and festivity, and a large number of influential persons attended to inspect and admire the machinery and hear the explanations of Mr. Robert Hammond, the managing director of the company, and of Mr. Lowrie and Mr. Hall, the engineers under whom the station has been carried out. The guests were afterwards entertained at a dinner at Bailey's Hotel. Among those who visited the station were the Earl of Dunraven, P. Grenfell, Killingworth Hedges, C. A. Mocatta, C. G. Mott, F. de Murietta, B. Newgass, C. Nursey, Dillwyn Parrish, W. H. Peto, Theodore Pim, H. L. Raphael, George Richardson, D. Trail Robertson, George Rose-Innes, E. C. Sandeman, W. Booth Scott, C.E., B. Verity, and, of course, the representatives of the technical press.



View of the House-to-House Company's Dynamo Room at the West Brompton Station.

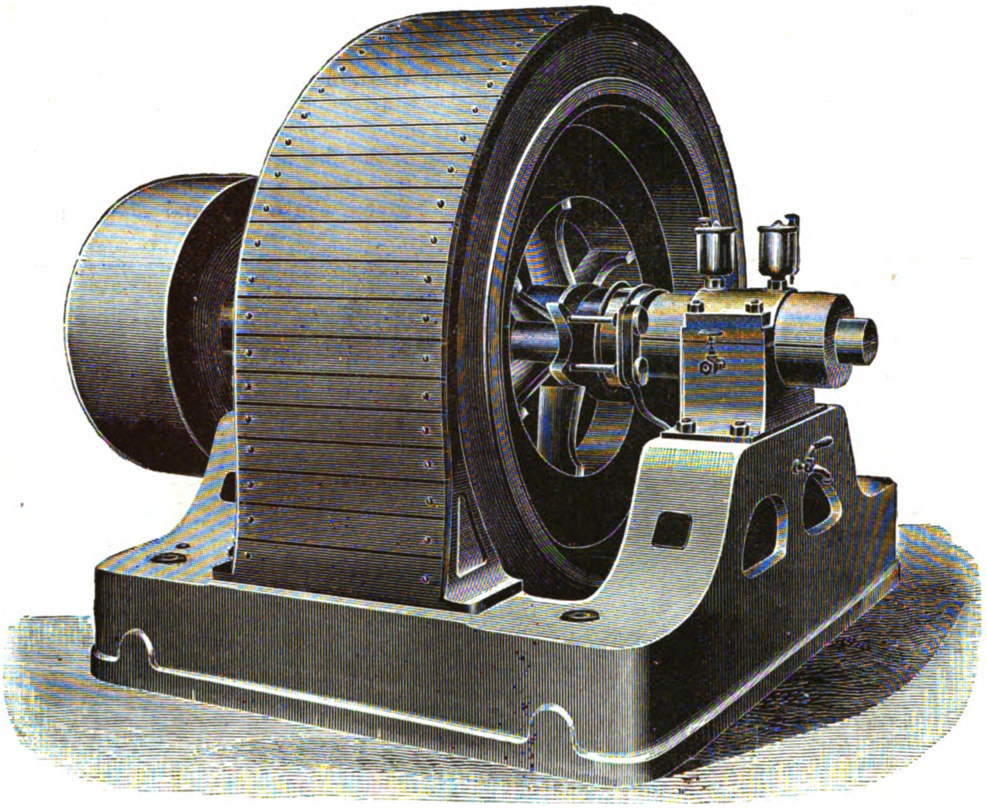
Earl Russell, Sir J. H. Puleston, M.P., Sir Owen Roberts, Sir Tindal Robertson, M.P., Sir Henry Roscoe, M.P., F. Wootton Isaacson, Esq., M.P., H. Seton-Karr, Esq., M.P., Samuel Montague, Esq., M.P., Henry Kimber, Esq., M.P., Hyde Clarke, Esq., F.R.S., W. H. Preece, Esq., F.R.S., Prof. Wm. Henry, F.R.S., Prof. George Forbes, F.R.S., Prof. Silvanus P. Thompson, D.Sc., Prof. W. G. Adams, F.R.S., Prof. Flower, F.R.S., Major-General Vatchell, Colonel R. T. Armstrong, Colonel Fitz-George, Colonel E. P. Meadows, Captain Cardew, Captain Morris, the Mayors of Brighton, Portsmouth, and Folkestone, Mr. Alderman H. Davey, of Brighton, Mr. Alderman G. Manwaring, of Hove, Mr. Alderman E. Martin, of Brighton, Mr. Alderman G. H. Soper, of Brighton, Messrs. J. Keith Angus, J. Spencer Balfour, J. W. Batten, A. Cassella, W. Lant Carpenter, J. C. Cohen, John Collinson, J. Crookes, F. Dethridge, Leon Drugman, R. W. Eddison, R. E. Farrant, W. G. Fossick, R. H. Fowler, A. C. Lorraine Fuller, Percy C. Gilchrist, J. E. H. Gordon, David Greig,

Description of the Station.

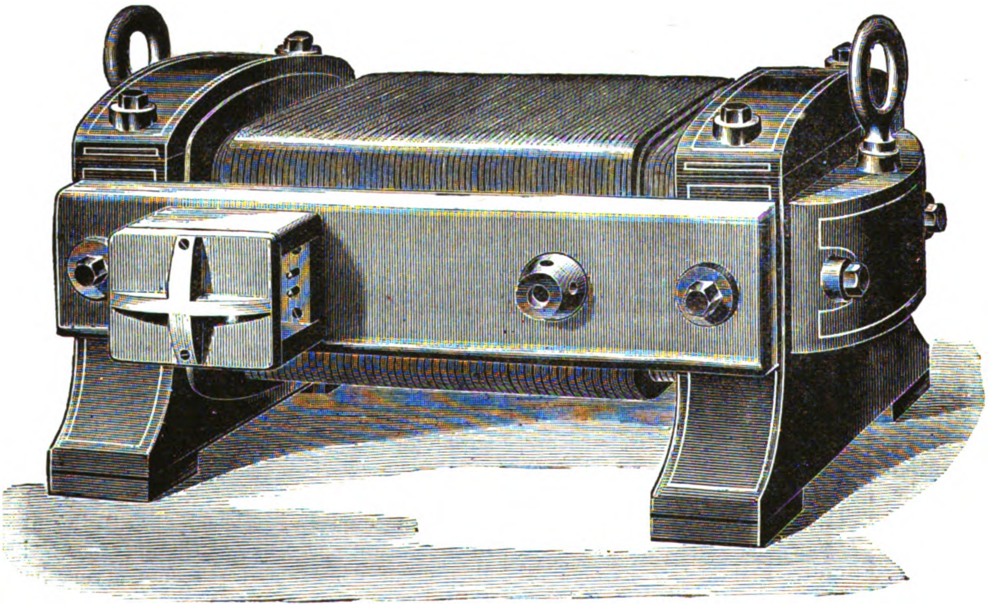
The site of the electric light station consists of a long strip of land 470ft. long by 60ft. wide, immediately adjoining the West Brompton railway station. The plan of the buildings is given in the accompanying illustration, which clearly shows, to scale, the position of the machinery, the portion of the site which is left dotted being reserved for extension of the system. On going down the inclined cartway one sees the offices and shops at the right hand. These are hardly yet finished, and the scaffolding is still up. Over the last of these buildings is an immense water-tank for supply of the boilers, fitted with its indicator. At the bottom of the cartway the station proper begins, and this is closed in by an immense corrugated iron partition. Inside this is the first boiler-house, further boilers being able to be added in the vacant space nearer the entrance. The boiler-house at present constructed presents a very handsome appearance, from the engineer's point of view, and is very conveniently arranged. High stacks of cast-iron framing enclose the six boilers, which are of the latest Babcock and Wilcox type. Further along are two Worthington pumps for pumping feed water into the boilers. Feed heaters are arranged on the inlet pipe, by which the waste heat of the exhaust is utilised, but no attempt is made to save the heat of the products of combustion going into the chimney-shaft A sump-pit has been dug near the boilers, into which the escape water drains, and into this the blow-off is led and condenses into seven feet of water, any escaping steam being

Digitized by Google

led off into the chimney-shaft by a pipe from the pit. The dynamo and engine-room is entered through another partition, and is certainly a very pretty and well organised arrangement of plant. The effect, even on looking at the present three sets of dynamos, as shown in our illustration of the engine-room, is very fine, and when the whole of the proposed plant is at work will be one of the finest exhibitions of machinery in London. A noticeable feature is the air of cleanliness and quiet—almost of solemnity, after the rattling of some dynamo-rooms—which is obtained by the beautifully-balanced slow-moving engines, the boxed-in dynamos, and the rope gearing. No difficulty is to be expected on the score of nuisance of machinery.



Lowrie-Parker Dynamo.



Lowrie-Hall Transformer.

The arrangement of the foundations of the engines are a special point in this installation well worthy the attention of electrical engineers. Instead of simply laying blocks of concrete, very often the only foundation, the foundations here are laid out with strong walls in hand-pressed gault bricks set in cement, and built directly to take the strain of the belting between the engines and dynamos, afterwards filled in with concrete. Party walls are placed to take the side strains, and foundations for the exciting dynamos are built in a similar way. The engine foundations are separated entirely from the outside walls, which are thus subjected to no strain from the machinery.

ENGINES.

The engine-power consists at present of three horizontal coupled compound engines, built to the specification of Mr. William Lowrie by Messrs. John Fowler and Co., Leeds, capable of indicating easily 250 h.p. Steam is cut off from the high-pressure cylinder before the piston has completed more than one-third of its stroke. The details of the engines are as follows: High-pressure cylinder 15in. diameter, low-pressure cylinder 25in. diameter, stroke of engine 30in., initial steam pressure 150lb. per square inch, speed 88 revolutions per minute, approximate weight of engine 24 tons.

The cylinders are fitted with separate liners, accurately turned to places, and forced into position by hydraulic pressure. Both cylinders are steam jacketed, the low-pressure cylinder jacket being supplied with steam from the intermediate receiver. Both ends of cylinders and valve-

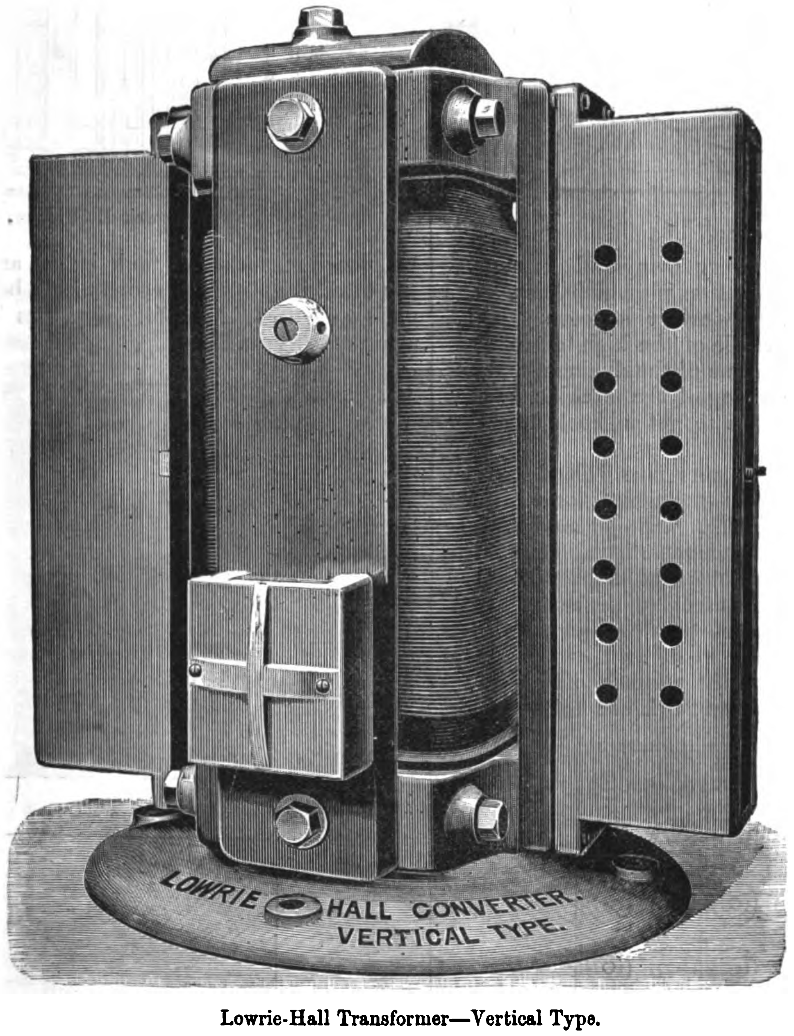
Digitized by Google

chests are fitted with large waste water-cocks with long barrels, close ends and glands, and coupled direct to a main drain pipe. All the cocks on each cylinder are joined together by rods and levers, and brought, with handle, within easy reach of the man standing at the starting valve, and all glands throughout have oilcups formed in the flanges and fitted for syphons. Cylinder lubricators are fitted to both valve-chests, and an extra sight-feed cylinder lubricator is fitted to high pressure steam-chest. The low-pressure cylinder is fitted at both ends with automatic relief valves; both valve-chests are provided with a 7in. steam pressure gauge and cock. All outer surfaces exposed to radiation are covered with a non-conductor and finished with sheet steel lagging. The steam feed is from above, the connecting pipe between high and low pressure cylinder dips beneath the ground line, and the exhaust is from the bottom side of the low-pressure cylinder. The main bearings are enormously strong: each is cast in one piece with the base plate, and fitted with brasses of the very best gunmetal, arranged for top and side adjustment; these bearings are 16in. long, and provided with two combined sight-feed and syphon lubricators, oil throwers, and catchers. Each engine is fitted with a heavy flywheel 14ft. diameter, made in halves, planed and joined through the centre, turned on the edges, and with turned grooves on the face, for driving with seven ropes, 1½in. diameter. The governor is Hartnell's latest patent, driven from the shaft by four cotton ropes, and controls the engine by acting directly on both the high-pressure and low-pressure expansion valves, giving a range of cut off in the high-pressure cylinder from 1 per cent. to 60 per cent. of the stroke, and governing the engine to within 2 per cent. A complete set of indicating gear is fitted to each cylinder, and a very neat little speed counter by Schaeffer and Budenberg, which can be reset to zero by a few turns of the key, counts the number of revolutions every day.

Dynamos.

The dynamos are Lowrie-Parker dynamos, designed by Mr. Lowrie, and made to specification by Elwell-Parker, Limited, Wolverhampton, and patented by Messrs. Lowrie and Parker (specification No. 12,907, 1888). They are multipolar alternating-current machines, capable of maintaining, economically and safely, an output of 100,000 watts. The dynamos are worked well within their limits, the current in the armatures never rising above 2,000 amperes per square inch of section. The working E.M.F. is 2,000 volts, the number of alternations 10,000—or 5,000 complete phases per minute (83 phases per second). The speed is 380 revolutions per minute, and the mean speed at the revolving surface is about 6,000ft. per minute.

The machine is the same as first employed at Eastbourne and Brighton, but sundry small improvements have been introduced. The Lowrie-Parker dynamo is designed upon the principle of fixed armature and revolving field-magnets, but, unlike Mordey's machine of this type, iron is largely employed in the armature.



Lowrie-Hall Transformer—Vertical Type.

Mr. Lowrie considers the use of armatures without iron disadvantageous, for the reason that the rapidly rotating magnet must tend to drag round the strongest portion of the field out of position of greatest utility. The greatest point of interest about these machines is the fact that nearly the whole of the copper strip in the armature—about 87 per cent. of the whole—is in the active part of the field, only a small portion of the coils, and those the turns lying parallel to the direction of rotation, being idle, rendering the machine both economical of copper and extremely efficient. The construction of the dynamos can be readily understood from the sketches of the details which Mr. Lowrie was kind enough to give us. The armature consists of a large outer ring built up of laminated iron discs, 5ft. in diameter and 5in. wide. On the inner face of this ring are simply planted the copper coils, which are kept in place by wooden strips screwed to the outer frame of the dynamo. These coils are wound upon a core of wood, very slightly concave to the radius of the machine. The copper is in the form of strip, ⅜in. wide by 1 millimetre thick, insulated with braided cotton saturated in shellac, with some

Digitized by Google

where about 30 turns on each coil. The end of the strip is connected in series to the inner end of the next coil.

There are 28 coils lying thus on the face of the armature-magnet, the ends being taken inside the frame to two terminals inside a small cupboard in the casing of the dynamo. Connection is also made with a single coil, and from these all measurements with ammeter and voltmeter are made. The construction of the standing armature

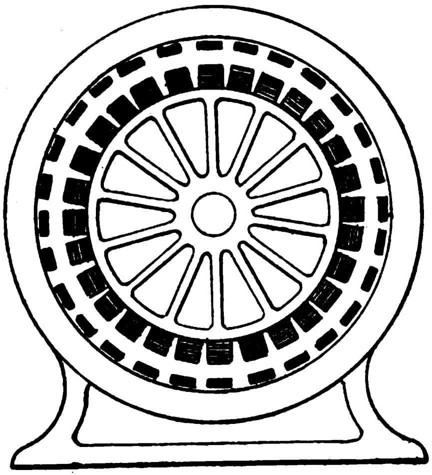


Diagram of Dynamo.

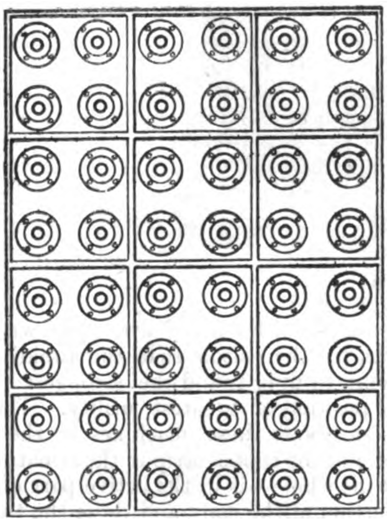
with the outer iron ring is thus very strong and permanent, and no fear of bending or side motion is possible, as may be the case with armatures—revolving or stationary—with simple built-up strips. The whole of the high-tension connections are made inside the frame of the dynamo, and the two terminals are inside the casing of the machine, so that it is impossible for a workman to get a shock unless he unscrews the casing.

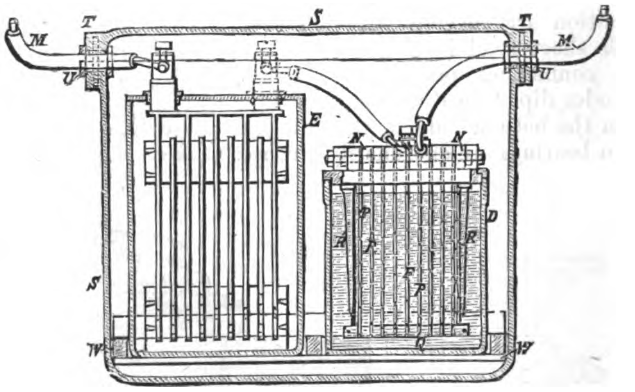
The magnets, also 28 in number, are bolted to the circumference of a 2½in. solid soft iron wheel, forged, without weld, out of one solid piece. Special methods are adopted to prevent the magnet-coils from flying off by the tangential force of rotation, the arrangement of which can be seen in the sketches. The cores of the magnets are rounded at the corners to allow of easy winding, but the edges are left sharp at the outer part, and serve as projections to carry the collar of the magnet-coil. Two T bolts pass through the magnet-core, and are bolted firmly



Switchboard.

to the iron ring. The arms or spokes carrying the iron ring occur at alternate magnets, so as not to magnetically short-circuit the cores. The magnets are wound with No. 8 wire, and carry eight amperes exciting current. An incidental advantage of this dynamo may be mentioned, and it is, that instead of, as usual, the E.M.F. dropping in working under full load as the machine gets hot, the construction of the magnet ring, on any heating taking place, expands the ring and pushes the magnets slightly closer to the armature, increasing the strength of the field. The E.M.F. is slightly higher when heated than when cool.

The bearings of the dynamo are exceptionally strong and heavy, so that there is little fear of heating; but, in case of emergency, the bearings are all water-jacketed with supply from the water-tank, so that a constant stream of cold water can be carried around them. The bearings are split, and the tops can be easily lifted off. The brasses are made so that the lower brasses can be revolved in their grooves, and knocking out for repair or replacement. All lubricators are combined syphon and sight-feed. The bearings, 20in. long, with side collars on one bearing to take side play. They are fitted with double oil grooves to catch the waste



Lowrie-Hall Meter.

oil, which is run into a tank below and used again. The use of oil is extremely economical; best pure hydro-carbon oil is only used, tested for impurities before use, and used again and again.

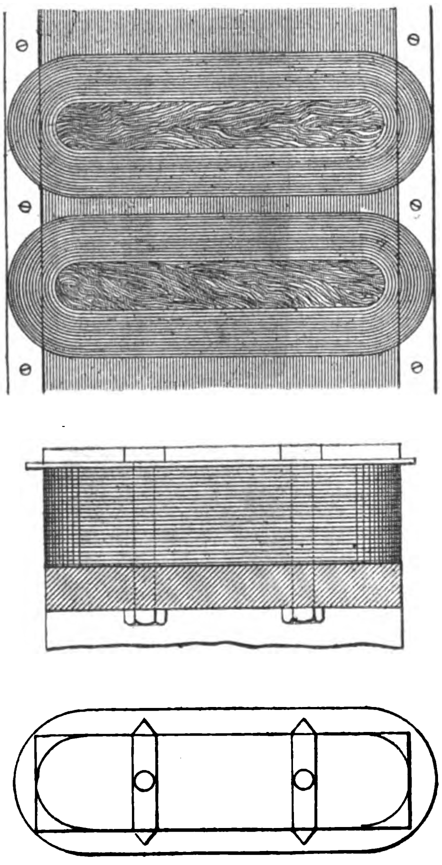


Diagram of Coils: Plan and Elevation of Magnets.

At Eastbourne, the oil consumption is stated as being only one quart of this oil in a year—practically, only the loss from tap-drippings. The lubricators on the engines also are all standing, arranged not to be in the moving parts, and are all fitted with combined syphon and sight-feed lubricators.

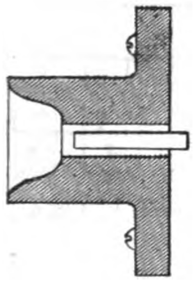
The exciting current is supplied by a small Elwell-Parker dynamo. A tachometer, by Schaeffer and Budenberg, Magdeburg and Manchester, is run from the axle of the dynamo for indication of speed. The weight of the dynamo is 10 tons.

Digitized by Google

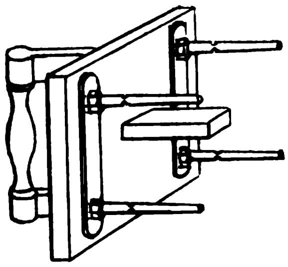
Tightening arrangements are made for adjusting the rope gearing. Around the dynamos is a highly insulated platform raised 6in. from the ground, of crossed floorboards on joists, with bitumen between the joists, and linoleum over all.

Switch and Test Room.

All wires are brought underground to the testing-room, and are brought up at the back of the switchboard. All connections are made behind, and it is impossible accidentally to touch the high tension connections. The switchboard is constructed in chinaware, mounted on ebonite, of the form shown in sketch ; connection between the dynamos and mains is made by insertion of the connecting-block with four brass pegs. This slides in the china cups, and it is impossible, by reason of distance of pegs, to short-circuit the dynamo. Any circuit can be connected to any dynamo—as shown in the diagram of circuits.

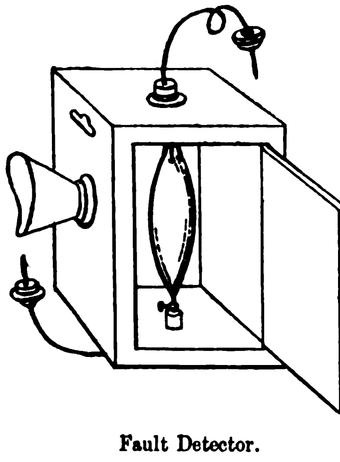


Section of China Cup of Switch.

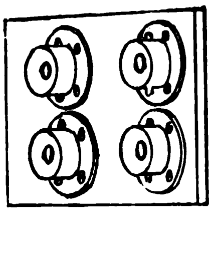


Connecting Switch.

The regulation of the dynamo is effected to within a variation of 1 per cent. by the Lowrie-Hall regulator, already fully described by us (vol. ii., pp. 283, 319). In this the heating effect of the alternate current is utilised. The sag in a long iron wire lengthened by heating, moves, without the disadvantage of friction, a tipping lever which sends an electric current one way or other, and alters a liquid resistance inserted in the exciting circuit. The action is very perfect.



Fault Detector.



China Switch Blocks.

An ingenious method, devised by Mr. Lowrie, is used to test the insulation of the underground mains. On every circuit carrying high-tension alternating currents, a certain static charge is generated. If the insulation is perfect, this can only escape to earth at the dynamo terminals. This static charge is here utilised to show a glow discharge, when the switchboard terminal is connected to earth, in a vacuum tube, arranged in a dark box, with a funnel for inspection, as shown. The degree of luminosity seen is a test of the insulation of the mains.

The Underground Mains.

The mains are all to be laid underground in iron pipes, and special details have been worked out for the junction pieces and street boxes. Three sizes of pipe will be used, 3, 4, and 5in. diameter. The junction pieces for these are all arranged with the same size connecting plate and screw-holes, and the street boxes are, therefore, all of one size The street boxes are constructed in two parts, the upper one with lid and spring lock, to be easily got at, the lower box being able to be set in the roadway when repairing, and filled up to desired level with bitumen or concrete.

The mains themselves are of special make, being Tatham's insulated cable, supplied by Fowler and Co., Leeds. The insulation is the highest yet made for cables, being stated as 32,000 to 43,000 (thirty-two to forty-three thousand) megohms per mile tested under water. The insulation consists of nine braidings saturated with a patent solution, and the cable is then lead-covered, and has a coating of hemp over all. The cables are made in five standard sizes, for supply of 2,000, 1,500, 1,000, 500. and 250 16 c.p. 50-watt lamps at the distance of one mile, with a loss of 2 per cent., the latter size being the least that is convenient for mechanical reasons. The cables are simply drawn through the cast-iron pipes. The leads have already been laid along Braham-gardens, Barkeston-gardens, Collingham-gardens, etc., and some forty houses are wired ready for connection.

Transformers and Meters.

The transformers used by the House-to-House Company are shown in the illustrations. Two forms are used, upright and horizontal, for use according to the position. The Lowrie-Hall meter has been fully described by us (see vol. ii., p. 248). Its action may be briefly described as a combination of secondary cell and electrolytic cell; the alternate current not having any effect upon the electrolytic cell, the secondary cell acts in its own direction along the circuit proportionately to the number of lamps alight, the electrolytic effect being thus the measure of the current.

The whole of the electric machinery and apparatus is distinct from other systems, and is practically all new and original with the company, designed and carried out under the supervision of the engineers, Messrs. Lowrie and Hall.

Congratulatory speeches to the House-to-House Company were made at the dinner at Bailey's Hotel by Mr. Preece, Prof. Forbes, and others, but we have no space to do more than allude to them. (For further illustrations see next page.)

REPORTING AT THE INSTITUTION.

To the Editor of The Electrical Engineer.

Sir,—Surely the council of the above Institution have committed a blunder by prohibiting the Press reporting papers, etc. I am afraid this must have a serious effect upon the membership. We in the provinces have always been heavily handicapped, and now we will know nothing of the Institution's proceedings until months after. Surely the fact of our being debarred from the use of the library unless we visit it (a benefit which is also given to the general public), might have caused the council to consider carefully before they applied the closure to the Press. We cannot deny there has been a vast amount of gratuitous advertising done at our meetings; but it is well known that the greatest sinners in this respect have, at one time or other, been members of the council. Why should there be any difficulty in so arranging matters that our worthy secretary should, with a few strokes of the pen, make short work of such advertisements ?—Yours, etc.,

A Provincial Member.

Glasgow, 29th January, 1889.

RED WIRE v BLACK.

To the Editor of The Electrical Engineer.

Sir,—In specifications for wiring it is frequently stipulated that red wire be used for the leads, and black for the return.

Although there may be some slight advantage in this arrangement, we feel sure that no one would wish to insist upon its adoption at a sacrifice of efficiency.

We have invariably found, especially in damp situations, that the red wire shows a marked inferiority both in insulation and durability, and we shall be glad to hear whether this is confirmed by the experience of other electric light contractors.

We may add that this applies to wires of all manufacturers that we have employed.—Yours, etc.,

Drake and Gorham.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

INAUGURATION.

Many writers have divided mankind into two classes, though the names given to the classes are not always the same, so we may venture to divide companies into two classes, one of which includes those that intend to work, the other includes those who don't so intend. Happy is the managing director of the former concern, when after promotion and organisation he can invite his co-directors and the public to see for themselves that work is going on satisfactorily and successfully. Now we were among those who might be said to have written hard things about the House-to-House Company, but we never for a moment doubted the settled intention to proceed energetically to work. Financial arrangements may be looked upon with suspicion, while good, sound commercial work may receive its own modicum of praise. There is no intention to discuss the ever open question of advisability of a central station here or of a central station there, of competing companies, of overhead or underground distribution, or of alternate v. direct current supply. There is undoubtedly a new, and we hope a permanent, development of the electric lighting industry, and without demur from anywhere we fancy that the new station of the House-to-House Company at Brompton may be recorded as a proof of it. Kensington Court, the Grosvenor Gallery, and the Whitehall installations are, if not old friends, specimens of the energy of those workers who never lost hope, while that at Brompton is the work of a recently formed company, which will no doubt ask the public ere long for further support. The directors have something to show for the money previously invested, and it will be for them to make out a good case for further confidence. When the time comes for this operation, we shall probably have an opportunity of testing the statements and saying something on the subject; meanwhile our remarks will stray no further in this direction.

So far as experienced judges can ascertain, the details of this installation have been carefully thought out; and if any weakness is suspected, it may perhaps be in the mechanical details of the dynamos. It speaks well of the engineers that free access has been given to their colleagues in the profession to inspect every detail. Mr. Lowrie must have been pretty certain of himself and of his plans before he submitted them to the examination they have undergone.

The principal guests at the inaugural ceremony, described more technically elsewhere, no doubt were invited for various reasons, and their opinions upon technical matters are valueless. Most of them would know an engine from a dynamo—when they were told, but further their education has not gone. Other guests, however, at the ceremony were designers of other stations, and they were fully able to appreciate

Digitized by Google

the difficulties that have been encountered and overcome. When central stations become as plentiful as gas works, when those engineers who have designed them are reckoned by hundreds and not by units, then, and not till then, will the designing of such work be undertaken with a feeling akin to indifference, such a feeling being engendered by a thorough knowledge of what has been done in numerous cases, how it has been done, and with what amount of success. The engineers of the Brompton station have received a certain apprenticeship at Eastbourne; they have there succeeded, and have here followed the lines dictated by their own experience. Precautions have been taken to enable the plant to be increased without difficulty to about three or four times its present capacity.

Reference may be made to certain remarks of Prof. Forbes and Mr. Preece in their speeches at the dinner after the inspection of the works. Both gentlemen compared the lighting of the streets of American towns with the lighting of streets in English towns, and the comparison was not flattering to England. Mr. Preece ought to know if anyone does, for his experience with them is great, that the ruling powers of the greatest city under the sun, who should have been among the first to welcome and introduce more light, are about the most difficult to change from the error of their ways. Procrastination is writ large all over the City, and those who arrogate to themselves the ideality of business acumen seem to know little and care less about the economic value of more light. The whole cry is, It costs more. So does the advertising of Pears over that of little Pedlington Smith, and yet Pears says it pays. The City fathers can't and won't see it in this light. To them more light does not mean more business, more quickly done and at less cost: it means one penny in the pound. Perhaps the rude remarks that have been made will assist in helping the "powers that be" to screw their courage up to the required point, and to not only advertise for tenders, but to plunge boldly and manfully into the work of giving more light in London streets. We don't want anything similar to gas; we want more, more, more. The inauguration of the Brompton station will prove how quickly, after the word to start is given, plant can be erected to give twenty, forty, sixty, or a hundred-thousand lights. It seems but yesterday the House-to-House Company was floated, and yet building and plant are ready to produce revenue. Next winter ought to see sufficient progress made to enable electric supply companies to supply current to light half London. We should like to here repeat our often reiterated remarks that if the companies would only keep as prominently before them the supply of power as they do that of light, what a boon they would confer upon commercial humanity, and their own shareholders.

THE SOUTHWARK SUBWAY.

From time to time rumours, more or less authoritative, have been floating about as to the motive power to be used on this line. The report of the company, which we give elsewhere, shows that the matter is at last definitely settled, and that Messrs. Mather and Platt have the work in hand. Our readers know how strenuously we have advocated electric as against every other form of traction in this subway, and though we knew of early negotiations with Mr. Holroyd Smith, and subsequently with Messrs. Siemens, we also knew that strong efforts were being made to put aside electricity in favour of other means of traction. However, all is well that ends well, and we have no fear of the success of electricity in the hands of the Bros. Hopkinson and Messrs. Mather and Platt.

The method of construction and the system of working of the City of London and Southwark Subway mark a new departure in the methods of communication in our large towns, and will probably afford a complete solution of the problem of underground railways.

The subway consists of two tunnels, each 10ft. 6in. in diameter, formed of segmented cast-iron plates. It extends from the Stockwell terminus at Clapham-road, by the Oval and the Elephant and Castle at Newington, and then under the Thames to the City terminus at King William-street, the total length of each tunnel exceeding three miles. There will be stations at the Monument, King William-street; Great Dover-street; the Elephant and Castle; the Oval; and at Stockwell.

As the method of construction, which is entirely novel, has been already frequently described, and interests mechanical and civil, rather than electrical engineers, we need not allude to it more particularly now, but, as we have said, it is only quite recently that the system of traction to be adopted has been definitely decided.

The original Act of Parliament specified that the traffic shall be worked by means of carriages, propelled upon the system of the cable tramway, but about a year ago the success of the Bessbrook and Newry Electrical Tramway and other similar undertakings led the directors to consider the adoption of electrical working, and they entered into communication with Messrs. Mather and Platt, of Manchester, on whose behalf Dr. Edward Hopkinson, the managing partner of their electrical department, prepared a detailed and elaborate scheme.

The matter was under discussion for some months, and finally tenders were invited from the most eminent electrical engineering firms. The result has been that the scheme of Messrs. Mather and Platt has been adopted in its entirety as affording a perfectly satisfactory and feasible solution of the problem, and a contract has been placed with them for the carrying out of the entire work.

The generating plant will be placed at the Stockwell terminus, where boiler and engine plant of over 1,000 h.p. will be erected and three large Edison-Hopkinson dynamos. The current will be conveyed by a lead-covered cable throughout the whole length of the line, and Dr. John Hopkinson's system of overhead conductors will be adopted for conveying the current to the locomotives.

This system has proved a great success on a small scale at Bessbrook, and is particularly well adapted for such an undertaking as the subway.

There will be 14 electrical locomotives, each capable of developing 100 h.p., which is sufficient for moving a train containing 100 passengers at 25 miles per hour, and for providing the great power required for starting rapidly.

The trains will run at intervals of three minutes, and will consist of three cars.

In addition to the plant required for electrical traction, Messrs. Mather and Platt's contract includes the lighting of the trains and of the stations, and of the hydraulic lifts and approaches.

The experience gained by Dr. Edward Hopkinson on the Bessbrook and Newry line, which, though on a much smaller scale, is still of the same character, and which has proved an unqualified success, has solved many difficulties in connection with electrical traction, and will be of great value in the present undertaking.

Mr. James Henry Greathead is the engineer of the subway, to whose designs the entire works have been constructed. Sir John Fowler and Mr. Benjamin Baker are the consulting engineers, and Mr. Spagnoletti the consulting electrician.

CORRESPONDENCE.

LITHANODE.

To the Editor of The Electrical Engineer.

SIR,—I have been asked by our consulting electrician, Mr. D. G. FitzGerald, to forward you some samples of "lithanode," which I now do. Hitherto, by the policy of other companies who previously owned and worked the lithanode patents, it has been most jealously shielded from the public gaze, and no samples have been issued for experimental purposes to the public.

My directors, however, have decided to issue such samples in small quantities to anyone who does not mind the trouble of applying for the same, enclosing a stamped addressed label. The plates I now send you may be cut up into smaller ones by the aid of a fret saw, thus forming a powerful, though small, battery of many cells, and will give with zinc as cathode 2·375 volts per cell; each ounce of

Digitized by Google

material will give one ampere-hour discharge in ordinary diluted sulphuric acid of specific gravity 1·170. The small plate will show the best mode of contact, but carbon blocks or rods bound on to the lithanode, or Bunsen battery clamps, with platinum foil, will answer the purpose.—Yours, etc., OSWALD SWETE, A.I.E.E.

The Mining and General Electric Lamp Company, Limited, Guildford-street, S.E. January 29, 1889.

CENTRAL STATIONS WORKED BY UNDERGROUND MAINS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I have just noticed in a back number of *Engineering* (March 23, 1888) a letter, which I send you, bearing on central stations worked by underground mains. Placed alongside the repeated and positive assertions of the House-to-House Company, it appears peculiarly interesting. Some of your readers may know of other instances in practical use.—Yours, etc., ONLOOKER.

"Sir,—I have read with pleasure Mr. Geipel's paper reprinted in your issue of March 9th (page 238), and beg to be allowed to correct several erroneous assertions in that paper. It states that, with the single exception of Eastbourne, there are no electric illumination plants on a large scale worked by the current from transformers and with underground conductors. Now as concerns this country (Italy) I am happy to state that during more than two years we have three very considerable central transformer installations, supplied with the well-known Zipernowski-Deri-Blathy system, which are entirely worked by underground conductors. The largest of these working installations is that done by the Anglo-Roman Gas Company, which lights already daily upwards of 5,000 lamps, and is continually extending. The other two plants, although not so large as that of Rôme, still are of very considerable extent; they are in the hands of the Italian Edison Company, Milan, and of Messrs. Bellair Brothers, Turin.

"All the underground conductors for these installations have been manufactured by the house of Siemens and Halske, of Berlin, who have taken special precautions for ensuring an irreproachable service, and have succeeded in making cables without perceptible waste of current by induction. These conductors are composed of two highly insulated concentrical conductors, protected against external and mechanical influences by a lead sheath and a double spiral band of iron. Upwards of 40,000 metres of such conductors have been laid in Italy alone, and nobody has ever complained of them

"Should you find it desirable I can give you further details. You would oblige by publishing these remarks.—

"I am, sir, yours truly, "EMILIO MAGATTI,

"Engineer to MM. Fratelli Moleschall.

"Rome, March 14, 1888."

[We take it that the references of the House-to-House Company are primarily to be taken as relating to England, where, with certain modifications, they may be regarded as approximately correct. As a rule, the work at Eastbourne is that regarded as the pioneer underground work. In London we have now the Kensington Court installation, not altogether in its babyhood, and the Whitehall installation, both actually at work.—ED. *E. E.*]

GAS ENGINE CENTRAL STATIONS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Electric lighting makes very slow progress in Britain; we often enough hear this, and it is a truism. We have now central stations in the principal towns in England, also in Glasgow, but the difficulties thrown in the way of establishing a central supply station in a town in the North makes one wonder that even so much progress has been made. In smaller towns than those above referred to, it is advisable, if possible, to prevent the gas and electrical interests clashing; however, the gas companies do not attempt to meet you half way. In a certain place, not unknown to those who seek the country for health or pleasure, it was proposed to erect a small central station as a pioneer of more extensive development to follow later on. The gas company, however, on being asked to treat with regard to the use of their product in gas engines as prime movers in an electrical plant, gave grudgingly a very minute reduction in price, and so saddled it with conditions as to laying mains to the works and so on, that it practically throws such a proposal out.

It appears to be a prevalent opinion amongst gas engineers that the use of an engine on any gas main will cause all the lights on that pipe to flicker and pulsate even with the modern anti-fluctuators now in use. Can we wonder that electricians do not attempt to harmonise with the gas interests, and also that electric lighting is so far behind our cousins in the States?—Yours, etc.,

C. H. YEAMAN.

Glasgow, January 25, 1889.

ELECTRIC METERS FOR CENTRAL STATIONS.*

BY PROF. GEORGE FORBES, F.R.S.

(Concluded from page 80.)

Ferranti Meter.—The next meter which I wish to describe is that of Mr. Ferranti. It is one so beautifully simple in its principle as to please one at first sight. It is founded on the principle that when an electric current passes through a fluid which is placed in a magnetised space, the fluid tends to move in a direction perpendicular to the current and to the magnetic action. The magnetic poles of circular form are placed one above the other, one being a north pole, the other a south pole. Between these two is a circular insulated trough containing mercury. The current enters the mercury at the centre of the trough, and the outer rim of the trough forms the other electric terminal where the current goes out.

The original instruments were intended for currents continuous in direction, and the magnets were excited by the electric current to a moderate amount, so that the magnetism was proportional to the current. Thus the moving force was proportional to the square of the current, and the friction of the mercury being approximately as the square of the velocity, the indications of the instrument would be accurate. Of course, the law I have spoken of is only true as a sort of approximation. The friction of the indicating mechanism follows a different law and affects the result. The number of rotations made by the mercury is indicated by the rotation of a float of special construction, resting on the mercury, connected by a spindle with a train of wheel work, which indicates the total number of revolutions. The meter has also been adapted for aberrating currents, and is rendered more delicate by having an additional shunt-winding of very high resistance. This circuit is put in multiple arc with the lamps on the two mains of the house supply. The friction of the wheel train is reduced to a minimum by employing the finest and lightest mechanism which can possibly be constructed. I am sorry to say that Mr. Ferranti has not been able to furnish me with any tests or specimens of his alternating-current meter, as he is even now introducing some improvements. I am told the range is about fifty fold, and that it is very accurate. I may mention, in praise of Mr. Ferranti's ingenuity, that both Mr. Edison and Mr. Weston, in America, two of the most prolific inventors, tried to work out a similar instrument and found it ineffective. The chief difficulty was one which, until Mr. Ferranti attacked the problem, has been taken as a universal fact—viz., that mercury is unsuited for a permanent contact. They found that the mercury got covered with a film or powder which interfered with its free movement.

Aron's Meter.—I now come to a very interesting type of meter, the principle of which was first suggested in this country by Professors Ayrton and Perry, and which has been made a practical instrument by Mr. Aron, in Germany. I have lately visited the central stations of Berlin, the largest existing on the Continent. These stations are the best equipped in the way of boilers, engines, dynamos, and accessories of any low-tension system I have ever seen. There is this defect, however, that they have hitherto used a distributing system with two instead of three wires. This fault will be remedied in the future. They supply at present current sufficient for a maximum supply of 26,000 incandescent lamps of 16 c.p. And here let me protest against the practice, beginning in this country, to take an 8 c.p. lamp as the normal one. Everyone is dissatisfied with the low candle-power prevalent in London, and, as a general rule, 16 c.p. lamps have been found in actual experience in hundreds of central stations to be the most suitable. The stations also light the Unter den Linden with 108 arc lamps of 15 amperes,

* Paper read before the Society of Arts, Jan. 23.

Digitized by Google

and the Leipziger Strasse with 36 arc lamps. The former is the finest piece of street lighting ever accomplished.

All the incandescent lamps are charged for by meter, and the Aron meter is always used. Originally it consisted of an ordinary clock, with a permanent magnet for the bob of the pendulum; below this a coil of wire is fixed with its axis vertical. The current to be measured passes through this and repels the magnetic pole, thus diminishing the influence of gravity on the pendulum, and causing the clock to lose time. The loss of time in any period, as compared with a good, uninfluenced clock, shows the number of units of electricity which have passed through the instrument. It takes a long time to test such an instrument over its whole range, and I have not been able to obtain any tests. The chief inconvenience of the instrument in its old form was that a clock could not be depended upon for accuracy more than about half a minute a week. One minute a week would be the smallest registerable quantity. Suppose this means one lamp-hour, then the maximum loss of the clock in the week being 12 hours, the instrument could not register more than $12 \times 60 = 720$ lamp-hours per week. Another inconvenience was having to wind up so many clocks every week. The former defect has been got over by mounting two clocks on the same framework, one in its normal condition, the other governed by the current. The two trains of wheels are connected by a differential gear with a third train of wheels with dials and pointers like a gas-meter. This increases the range of the instrument, so as to be practical. Of course, this improvement diminishes the accuracy of the instrument (1) by introducing more work for the clocks to do, and (2) by having to deal with the ordinary errors of two clocks, and every clockmaker knows that two pendulum clocks mounted on the same frame affect each other's going, and introduce errors. The principle of this meter is very beautiful, and in the Berlin central stations the authorities speak in very high terms of its value. Complaints from customers do come in, but in those cases the meters are tested, and found to work quite well. Its range is greater than for any other meter, being about one hundredfold, I believe.

This meter has been altered to adapt it for registering alternating currents by replacing the permanent magnets by coils, or electromagnets. In the central station at Rome, which is in many points the finest and best-designed station for alternating currents which I have yet seen, it is intended to test these meters. But I can say nothing about their accuracy. I will only point out that in this case the retarding influence varies as the square of the current, whereas, with the permanent magnet, it varies as the current. This does not lead us to hope for the same satisfaction as is afforded by the type for continuous currents.

Lowrie-Hall Meter.—I will now say a few words about a meter specially designed for alternate currents, which resembles the Edison meter more than any other. This is the Lowrie-Hall meter. A battery—preferably a secondary battery—is placed on the secondary circuit of a transformer. An electrolytic cell is also placed in the circuit. Now there is no complete circuit through the battery and electrolytic cell except when lamps are in circuit, and it is only then that electro-chemical decomposition can take place. The alternate circuit does not transfer metal from one plate to another. The whole effect in this way is produced by the battery, which acts as if the alternating current did not exist. The continuous current thus flowing is proportional to the conductivity of the current—*i.e.*, to the number of lamps at work. Thus the total number of lamp-hours, or Board of Trade units, is measured by the quantity of metal lost by one plate or gained by the other. This is an extremely novel and ingenious idea. One is inclined to ask how long the battery will stand the alternating current, and whether there is much trouble in charging and replacing the secondary batteries. I am informed that these meters have been successfully at work at Eastbourne for more than a year.

Schallenberger Meter.—A very practical form of meter has lately been brought out by Mr. Schallenberger, electrician to the Westinghouse Company at Pittsburgh, an extremely ingenious and accomplished electrician. It is intended for use only with alternate currents. This is not the place to go into a scientific examination of the theory of its action. I will try to explain it in popular language. A circular iron disc is placed on a vertical arbor connected with the correcting mechanism, and also carrying a fan to introduce resistance to movement by air friction. The iron disc rotates very freely. Two diameters of this disc are chosen, inclined to each other at 45deg. A coil of wire or copper ribbon fixed to the casing is coiled round each of these diameters. One of these coils is connected with one of the wires going to the lamps, and consequently has an alternating current flowing through it. The other coil is closed on itself, and has induced currents attaining a quarter of a period later than the main current—*i.e.*, when the main current is zero. Now consider the instant when the main current is a maximum. It magnetises the iron disc, and a quarter of a period later the induced current, acting at an angle of 45deg., tends to turn the disc in a certain direction. When the main current is reversed the magnetism is reversed, and the secondary current is also reversed, and hence rotation in the same direction ensues. Thus we have continuous rotation of the iron disc when an alternating current is flowing through the main coil. It is found that for a 15-fold range the number of revolutions of the disc indicate the total number of lamp-hours, or Board of Trade units, which have passed. This is a very convenient type of meter. It does not require great delicacy of construction, and is not liable to get out of order. The objection to it is that its indications vary with the speed of reversals of the alternating current, and our best governors are not perfect, and our most reliable suppliers of electricity would be tempted to alter its indications by increasing the speed of the engines a little. But the meter remains a beautiful practical instrument, which is doing splendid work in the United States. Mr. Schallenberger promised to send me one of these meters, but I am sorry to say it has not yet arrived.

Forbes' Windmill Meter.—Some years ago, when I first realised the value of the invention of Messrs. Gaulard and Gibbs, for distributing high-tension currents in the mains and delivering it as low-tension in the houses, I felt that one difficulty in the way of adopting it was the want of a meter for alternating currents. Such a thing did not exist, and I felt certain that the public would never be satisfied with a meter whose indications depended on the speed of reversals. It seemed to me that the heating quality of the currents was the only one which would succeed, and would be equally applicable to continuous and alternating currents. I was fortunate enough to have the kind assistance of Mr. A. Stroh for perfecting the details, and eventually the windmill meter was completed, in which the heat generated in a resistance sets up convection currents in the air, which work a kind of windmill. Here the force is proportional to the square of the current, and the opposing resistance is air friction, which varies as the square of the velocity, so that it was natural to expect that the indications would be accurate, and this was found to be the case.

The windmill which I use is made of a mica disc, with mica vanes round the edge attached to it by small pieces of pith. It has a hole in the centre, in which is fitted a thin paper cone, which has at its apex an aluminium cone, supporting a steel pinion with a ruby cup in its centre. This cup rests on a needle point, and the pinion works into the train of wheels which does the counting.

When this meter was perfected, it seemed that the English demand was not great, and it was best to modify it to suit the American market. I went to America to find out exactly what was wanted, and altered the instrument accordingly. The chief objection raised to it was the difficulty of mailing it, and a fear that it was too delicate. Consequently, I strengthened some of the parts, reduced the sharpness of the needle point and provided a metallic case in place of a glass shade. A considerable number have been sent across the Atlantic in both directions without any injury by the ordinary channels. On arrival all that has to be done is to loosen a screw, so as to free the windmill and let it play upon the needle point. The electric resistance of the conductor has also been objected to. This I was able to correct by altering the form of the conductor in which the heat is produced. Its resistance is now one-hundredth of an ohm, and Mr. Schallenberger after testing, at Pittsburgh, a batch which were sent direct from the workshop without any adjustment, wrote to me saying that they are quite accurate, and that the fall of voltage, due to resistance, is quite low enough, and that they were put to work on the regular commercial circuits. Mr. Westinghouse has acquired the rights for America, and is now manufacturing them at Pittsburgh. It is the only meter which he supplies for motors and continuous currents, and it also works equally well with alternating currents, of any speed of alternation. For alternating currents he has hitherto used the Schallenberger meter. The range of this meter is about 12 to 15-fold, about the same as the Schallenberger meter. If I used more delicate wheel work, the range would be greater.

I need hardly say that the perfecting of such a meter has led to innumerable experiments. Trials have also been made of a variety of other means of utilising the heat. I would not be doing my audience justice if I did not show them one other type which I have constructed, which is very simple and effective, but which has one slight defect, viz., that it is not easy to manufacture these in numbers all exactly alike. It consists of a wire conductor covered with cotton, which absorbs alcohol from a reservoir. The electric current being passed through the wire heats it and evaporates the liquid, which is condensed in a tube, where it is measured. This quantity is an exact measure of the quantity of electricity which has passed through. This instrument has not been used on commercial circuits.

Since the beginning of September, 1887, when I first exhibited the mill-wheel meter, an enormous number of patents for meters have been taken out, but I think I have described all that have as yet proved themselves to be of practical value. Each of the meters I have described has its merits, and all are doing good work in central station distribution.

NOTES ON THE DESIGN OF ELECTRIC MOTORS.

At the last meeting of the City and Guilds of London Institute Old Students' Association, held at the Central Institution, South Kensington, on January 30, the adjourned discussion upon Mr. Albion T. Snell's paper on "The Design of Motors" was resumed.

Prof. W. E. Ayrton, F.R.S.: At the last meeting of the association we had read to us a very practical paper by a very practical man, and such a contribution from one of the old students of the City and Guilds Institute, I think, not only does great credit to this association, but is of real value to the profession which so many of the old students have, I think, wisely embraced. Mr. Snell's labours for the past few years in Mr. Immisch's factory have so thoroughly borne out the theory that was put forward some seven years ago by Prof. Perry and myself as to the difference that ought to be borne in mind in the construction of a good dynamo and a good motor, that I do not think we are likely to quarrel on side issues. At the time, that is to say in 1882, when we put forward this idea that a motor and dynamo should be constructed in a different way, I am afraid we were regarded as rather revolutionary seceders from the orthodox camp, and I suppose, in fact I feel sure, that we have not yet been received back with favour by the orthodox. It is, therefore, a great pleasure to us to find from Mr. Snell's work that henceforth the unorthodox must be regarded as the orthodox. Mr. Esson's remarks were of extreme value, because they came from another very practical man; in fact, the sort of work that these men are doing, their being able in some way or other to find time in the exigencies of commerce and the drive of business to make scientific experiments, fills me with the utmost admiration. I think it was probably due to the existence of such men in the past having been ignored, that the professors rightly earned the title they received of being "musty bookworms," and I think it will be due to the full recognition of the labours of such men that this movement of technical education is likely to lead to success. There has been, you know, considerable discussion in the newspapers and elsewhere during last year—at the British Association, for example—as to the relative value of practice and theory. It occurs to me, as it does no doubt to those here, that the discussion is rather like an imaginary quarrel between the gun and the gunpowder, as to which made the cannon-ball go to its destination. There is no doubt that the practical gun without the gunpowder would not be able to do very much. On the other hand, there is equally no doubt that the spirited mathematics of gunpowder would be wasted energy—a mere flash—a mere useless puff—had its energy not been properly controlled nor been properly directed by the practical gun. It is, in fact, by a combination of theory and practice—I may say perhaps practice and theory—that we are likely to get to success in this or in any other industrial investigation; and, therefore, if I make any remarks which appear to savour of a critical character, it is to be understood that the criticism is very far from being hostile. It will be merely suggestions I shall throw out for the purpose of enabling us to go hand in hand—practice and theory—to arrive at what we are all aiming at—that is, truth; or, put it another way, to obtain a really good motor—whatever the construction we are ultimately to adopt. It is, in fact, by theory walking hand-in-hand with practice, by the Professor co-operating with such man as Mr. Snell and Mr. Esson, Mr. Reckenzaun and Mr. Mordey, that we are likely to come to success, and not by the one fighting against the other and trying to find out whether the gunpowder or the gun makes the bullet go. Mr. Esson's remarks in regard to his experiments, I confess, were a little staggering. He brought forward statements which were to this effect—that if certain currents were sent through a machine, running at a certain speed, the E.M.F. developed was the same, whether it was worked as a dynamo or as a motor; because it is obvious that if that conclusion was universally true, then the whole theory that we propounded in 1882 as to the action of the armature in a motor—and, indeed, the theory which to a great extent has led Mr. Snell and Mr. Immisch to the success they have arrived at—would be groundless. Before the end of last meeting I was, however, able to see what was the fallacy of his conclusions. It was this. He had been experimenting on dynamos used as motors, and not on motors used as dynamos. This difference was a very important one. The armature of a good modern dynamo is, as you all perfectly well know, wound with but a few convolutions of wire, is but a weak electromagnet. Therefore, if he has succeeded in proving that the addition of a weak electromagnet to a strong electromagnet, whether with a plus or minus sign, produces but little change, I venture to think that that does not really add much to our information as to what happens in a motor. The fact that you prove that A plus a small quantity is practically equal to A minus a small quantity does not at all prove that A plus a large quantity is equal to A minus a large quantity. Immediately after the meeting, before we had left the room, I suggested to Mr. Mather that he should make the same sort of experiments that Mr. Esson had made, but not to make them on a dynamo, but on a motor, and for that purpose Mr. Mather, with the assistance of two of the students, Messrs. Drew and Wright, selected an Immisch motor, and made the experiments Mr. Esson described to you. They ran that motor both as a motor and as a dynamo. As a matter of course you run it as a motor by current supplied; and as a dynamo you have to drive it by an independent source of power. The same current was as nearly as possible maintained in the two cases, and the speed was maintained. Various currents were used for different experiments, but the same currents when the machine was used as a dynamo and when run as a motor. Owing to the field of the armature being somewhat large, there was some difficulty to get stability when run as a dynamo. Of course that was easily got over by supplying an independent source of current, so that we could work at the same part of the curve when the machine was used as a dynamo and when used as a motor. And the result, I am glad to say, from our point of view, completely disproved Mr. Esson's statements, because experiments show that when you take the Immisch motor, and run it as a motor, and afterwards as a dynamo, you get more certain conclusive results, shown in the following table:

Experiments with an Immisch Motor. Speed throughout 1,400 Revolutions per Minute.

Series A.—Armature turning WITH *the brushes.*

Amperes.	Volts at teminals.	Volts used in armature.	E.M.F. developed in armature.
	I.—Run as a motor.		
12	31	2·3	28·7
14·3	35·5	2·7	32·8
15·2	38·5	2·9	35·6
	II.—Run as a dynamo.		
12	20·5	2·3	22·8
14·3	24·4	2·7	27·1
15·2	26·9	2·9	29·8

Resistance of armature in experiments I. and II. was 0·189 ohm.

Amperes.	Volts at teminals.	Volts used in armature.	E.M.F. developed in armature.
	III.—Run as a motor.		
12	30·2	2·5	27·7
14·3	35·8	3	32·8
15·2	38	3·2	35
	IV.—Run as a dynamo.		
12	20·5	2·5	22·3
14·3	23·5	3	26·5
15·2	26·5	3·2	29·7

Resistance of armature in III. and IV. was 0·287 ohm.

Series B.—Armature turning AGAINST *the brushes.*

Amperes.	Volts at terminals.	Volts used in armature.	E.M.F. developed in armature.
	V.—Run as a motor.		
12	30·8	2·64	28·16
14·3	35·2	3·15	32·07
15·2	36·2	3·34	32·86
	VI.—Run as a dynamo.		
12	22·3	2·64	24·94
14·3	25·8	3·15	28·95
15·2	27·7	3·34	31·04

Resistance of armature in V. and VI. was 0·22 ohm.

If now we compare I., which is the most favourable when the machine was running as a motor with the brushes, with VI., which is the most favourable when the machine was running as a dynamo against the brushes, we have:

Amperes.	E.M.F. developed in armature of Motor.	Dynamo.	Difference in percentages of smaller.
12	28·7	24·94	15
14·3	32·8	28·95	13
15·2	35·6	31·04	15

This proves conclusively that there is a stronger field when the machine is used as a motor than when it is used as a dynamo. Whether it is possible to have this result, I will not attempt to discuss. Mr. Esson was rather of opinion last time that that was "physically impossible." Well, it may be a physical impossibility, but it happened in the dynamo-room below. These are the results that Mr. Mather, with the assistance of Messrs. Drew and Wright, gave me for the experiments with the Immisch motor running one way or the other. Every single result for a motor is distinctly higher than it is in the case of the dynamo. Of course, that also disposes of Mr. Esson's objection that self-induction was of no consequence. He said in mentioning some experiment when he found that $V + C R$ [reading from the *Electrical Engineer* of January 18] $= V_1 - C R$, where C was the current and R the resistance of the machine, "I conclude that the effect of self-induction might be neglected." Well, of course, that is all disposed of in exactly the same way for the same reason. He was dealing with an armature with a small number of convolutions, and not with an armature of many convolutions. If you have an armature with a small number of convolutions, the coefficient of self-induction, which depends on the square of the number of turns, and therefore increases very rapidly, is of little consequence. But that does not apply to a motor at all. There the addition of the armature field is a distinct feature in the motor, and I believe the effect of self-induction may be of considerable importance.

At the beginning of Mr. Snell's paper there are one or two statements which no doubt he will clear up by modifying the wording. He says, "It is now generally admitted that the effect of self-induction in the dynamo armature is to increase the lead, while in the motor it tends to diminish it." I am not sure whether I agree with that statement. The effect of self-induction is a twofold one. It is, of course, to diminish the current which passes with a given potential difference and given resistance. It is also to delay the current. Well, it is a little difficult to say what is the resultant effect in the particular case of a rotating armature. The two effects, you see, will somewhat oppose one another. The effect of delaying the current, no doubt, is to shift the poles round, and therefore the effect of delaying the current is to increase the lead of the dynamo, and diminish the lead of the motor. For, if you assume that there is a negative lead with a motor shifting the poles round, it will bring the line of commutation nearer to the neutral position with the motor. But if you take into account the weakening of the current due to self-induction—possibly, however, that was not what was intended—then I am not so sure that you can come to the same conclusion. It is most important to remember, when speaking of self-induction, that there are always two effects, the weakening and the retardation, and they may not always help one another. If, for example, in the case of a watt-meter used with alternate currents you take into account not merely the weakening,

Digitized by Google

but also the retardation, as you must do, to treat the question properly, the results given in the books will be found to be completely reversed. He goes on to say Mr. Mordey has pointed out that in the generator the effects of self-induction in the armature windings are opposite to those of the Foucault currents in the core; but in the motor they tend to increase each other. There, again, it is a little complicated as to what is really the effect of self-induction. There is no doubt about this, that the Foucault currents in the core of an armature are in the same direction as the currents in the winding, and therefore, whatever effect the currents in the windings may have, there will be the same sort of effect produced by the currents in the core, and therefore there is no doubt whatever that in a dynamo the currents in the core tend to weaken the field as well as the currents in the windings. On the other hand, the currents in the core in a motor will tend to weaken the field, whereas the currents in the armature increase the field, as experiments show. So far you may say it is right; that is. currents in the core of a dynamo assist the currents in the windings of the armature, and both weaken the field. In a motor the currents in the core oppose the currents in the armature, and, while the currents in the armature tend to increase the field, the currents in the core tend to diminish the field. If, instead of speaking of the effects of self-induction, Mr. Snell had spoken of the currents in the armature windings, and of Foucault currents in the core, he would have been perfectly right. The effects of self-induction is, I confess, a little complicated. As Mr. Snell has pointed out, it is of value to short-circuit the coil in the armature of a motor when it passes the brushes, and not good to short-circuit the coil of a dynamo armature when it passes the brushes. In the Immisch motors, the coils when they pass the brushes are short-circuited, and this is of distinct value for this reason: That when you short-circuit these coils you get currents in the coil which oppose the current in the armature itself, and therefore the shifting of the field, due to the currents of the armature, is balanced to a certain extent by the current of a short-circuited coil. In a dynamo it is the opposite, because in that case both currents would be in the same direction. Practically, then, short-circuiting the coil in the armature of a motor enables you to keep the brushes in a fixed position; whereas, if you short-circuit the coil in the armature of a dynamo, it tends to make the lead increase more rapidly with the increase of current in the armature. Now, of course, one of the great objects aimed at in modern machines—dynamos and motors—is to enable you to have the brushes in fixed positions without sparking when the current in the armature is increased. That object is approached more nearly by short-circuiting the coils of a motor, and would be departed from by short-circuiting the coils in a dynamo. Mr. Snell, in fact, suggested that to me some little time ago, and I may mention that, in passing, as bearing out what I have just said about the Foucault currents. On page 60 of the *Electrical Engineer*, Mr. Snell gives an expression for the torque where he says $\left(T = \frac{Z_a N t C_a}{2\pi} \ldots\right)$ in one coil of the armature. I do not know whether in working out that formula he has used some particular method of counting the lines of force. Possibly he can tell us whether he has taken some particular number as the unit number, and not used the ordinary number in the electromagnetic system. If he has, of course there is no objection to the omission of the various constants that would enter into the formula. I do not know whether he intends that. If he does not, then I confess I do not quite see how the formula has been arrived at or how you can ignore, for example, the conversion of watts into horse-power, when you express the torque in pound-feet.

Mr. Snell: It is intended to be in C.G.S. units.

Prof. Ayrton: In C.G.S. units. I am not sure whether even in that case there would not be a constant.

Mr. Snell: I will explain it when I reply.

Prof. Ayrton: I should like to know why, on page 61, he says the field strength is to be relatively greater as the *size* of the machine is increased, and all through his paper he seems to admit that for large motors it is right to have a large field-magnet and comparatively weak armature, whereas for small motors it is right to have a comparatively strong armature and weak field-magnet. It would be very advantageous if in his reply he could point out why he is led to that consideration. Of course, he may have been led to it by commercial reasons, the expense of making large armatures, being, of course, considerable. Theoretically, I do not see why you should not have a relatively large armature for the large motor as well as for the small motor. Indeed, I made some calculations with Prof. Perry, some long time ago, and we came to the conclusion that, taking the Edison-Hopkinson machine of a certain weight (46½ cwt.), that if that machine had been constructed with much larger armature and much smaller field-magnets, it would have had a horse-power of 100 or more, whereas the actual horse-power was only 48. That is to say, taking into account what theory seemed to lead to as regards the rate at which the power should increase with the size of the machine, and starting with the power of a small motor, like that of Mr. Immisch's, we concluded that the power of the Edison-Hopkinson machine, when used as a motor, was not nearly as great as it ought to have been.

Such a result would lead one to conclude, in the absence of further evidence, that the larger machine should also have, when used as a motor, a comparatively larger armature and a smaller field-magnet. Possibly, he will be kind enough to give us some information as to why ideas change as we pass from a small motor to a large motor. Then, on page 61, the reasoning seems to be a little complex—where he speaks about the internal E.M.F. of the motor as being the brake horse-power divided by the current. Of course, that is *not* the actual E.M.F. It is a kind of imaginary E.M.F., and he takes this E.M.F., which he puts as equal to the difference of potential, at the terminals minus the current with the resistance plus Lm, where Lm is the value of the "reactions of the motor armature," but I do not know that that is the right way of treating the subject. I do not see how you can subtract from the E.M.F. in that way and hope to get right results. You certainly ought to add a term to the resistance, and subtract from C R a term in consequence of the increased resistance of the armature due to self-induction, but I do not think you ought to subtract from C R a term due to reactions of the armature. Mr. Esson, at the end of his remarks (he will, I hope, speak again this evening: I will not detain you long) speaks about the relative modes of series and shunt winding in the Manchester machine in order to produce compounding. Surely there is some mistake about that!

We have downstairs a machine which can be used in a variety of ways, about which we know everything, that is to say, we know all the details of construction from the maker, we know all the details of its action from the experiments the students have made here. The particular machine can be used as a simple shunt machine by using only shunt coils, or as a series machine by using only the series coils, or it can be used as a series machine, putting the shunt coils in parallel, or as a series machine, combining the shunt coils in parallel with the series coil, and, finally, as a compound machine. Now, in that particular machine, certainly the ampere-turns in the series winding are not equal to the ampere-turns in the shunt-winding where constant P D is being obtained. In that machine the series winding occupies one-sixth almost of the whole winding on each limb of the field-magnet. That one-sixth of the volume of the series coil has 66 convolutions, and with a current of 30 amperes, which is approaching the maximum the machine ought to produce, there are 1,980 ampere-turns in the series winding on each limb. The shunt coil contains 2,320 windings on each limb, and when this machine is compounding (for it compounds extremely well at one particular speed) the shunt coil has 1·9 ampere passing through it, so that makes 4,400 ampere-turns on each limb on the machine for the shunt winding. You have, therefore, to compare 1,980 ampere-turns series-winding with 4,400 ampere-turns shunt winding. So far, therefore, from the series-winding being equal, it is not one-half of the shunt winding. Mr. Esson further considers the necessity of using so large an amount of series winding. It is large, even if you take the numbers I have given, although not nearly so large as the one he seems to imagine. He seems to think that the reason is to weaken the effect of the current going through the armature. Is that quite right? Is that the reason you want so large an amount of series ampere-turns? Is there not a totally different reason? Is it not because you are working on so high a part of the curve of magnetisation that in order to raise the volts by only a few, which is necessary to compensate for the loss of volts required to send the current through the armature, you require a large increase in the number of ampere-turns? You see, if you are working high up on the curve of magnetisation, then to increase the volts by only, say, 10 per cent., or it may be 5 per cent., which is necessary to make up for the loss of volts in sending the current in the armature, you must have a large increase in the ampere-turns. I rather think that is the reason why you want so many ampere-turns, and not in consequence of the diminution of the field due to the armature. There is one other point. I am very glad to see Mr. Snell has used the method that was suggested in our original paper for plotting out the results, namely, plotting out the curves for $\frac{E}{N}, \frac{e}{n}$, and $\frac{B.H.P.746}{n c}$. That is practically the way we treated the subject originally, and that method is no doubt an extremely good one for finding out the behaviour of a particular machine. To plot these three curves is no doubt an extremely good method of attacking the problem. I cannot sit down without expressing the admiration which I am sure we must all feel for the labours of Mr. Snell and for his kindness in bringing his paper before us, and especially let me end by saying, as indeed I began by saying, that any remarks of a critical character that I have offered are merely made good-naturedly, and not in a hostile spirit.

Mr. Reckenzaun: I did not have the pleasure of hearing Mr. Snell's paper read, but I have carefully perused its contents. I perused the paper several times in the hope of finding some points about which I might disagree, but I was unable to find fault with the practical part of the paper. My own views, which are based upon long experience, coincide with those expressed by Mr. Snell in his excellent paper. The knowledge that there is a decided difference between the reaction of the armature, when a machine is working as a motor as compared with when working as a dynamo, dawned upon me at a very early period, especially in the early days when literature on the subject was scarce, and when the paper of Profs. Ayrton and Perry was published some seven years ago. I made that paper a kind of textbook which I have been working to ever since, more or less, and I consider Mr. Snell's paper an excellent supplement to it. On an occasion, some six years ago, I used one of my little motors of ½ h.p. capacity to work as a generator. I wanted to generate a current from a dynamo, and no dynamo being at my disposal I used a motor, and I found that the same machine when running as a dynamo required 60 per cent. more speed to produce the same E.M.F. and current. This surprised me very much at the time—in fact, I was very much astonished; and in order to ascertain whether this result was due merely to the design, I made tests of every kind of dynamo that was at my disposal, and I tried each machine as a motor and as a generator, and then I compared the results. Among those machines were samples of the Burgin, Siemens, and De Meritens, and I had the pleasure of making some of the experiments in conjunction with Mr. Kapp at the time. I thought that to pick out the heaviest of these machines, which was the Burgin, it would probably give the smallest difference in the results. This machine weighed 912lb., its resistance between the terminals, cold, was 1·021 ohm, and the resistance of the armature between the brushes was ·5 ohm; it was a series machine, and I may remark that all my experiments at that time were made with series wound machines, purposely. The

Digitized by Google

results I obtained were as follows: with the Burgin machine, running at a practically constant speed, as a motor 1,076 revolutions, 17·8 amperes, 116·2 volts at the terminals, 2·67 e.h.p., 2·15 brake h.p.; running as a generator, 1,086 revolutions, which was as near as I could get it to the 17·8 amperes, 80·4 volts, 1·6 e.h.p. I then made another experiment by keeping the E.M.F. as constant as possible, and the current, and this will show how the speed varied. When running as a motor it was 728 revolutions, 19·4 amperes, 83·5 volts, 1·2 e.h.p., 1·46 brake h.p.; as a generator it made 1,100 revolutions, 19 amperes, 85·18 volts, 1·67 e.h.p. I calculate out this machine because it was the heaviest, and the one which had the heaviest field-magnets. I can only repeat that I agree in almost every part, at any rate, of the practical part, of Mr. Snell's paper, and therefore I cannot prolong the discussion any further, because I have no argument. I can only congratulate him and the profession at large on this very excellent paper which we have received.

Mr. E. W. Smith: Prof. Ayrton mentioned the short-circuiting the cores of the brushes. There are two arguments for it and one against it. Prof. Ayrton has given the one against it. Prof. Silvanus Thompson's favourite one for it is that you should short-circuit the coils just so long that they should get up the same current in the opposite direction, so that there should be no effects of self-induction when the coil is passed on the other side of the brush. The other argument is that the armature short-circuiting has not much effect in the dynamo because the armature field is so weak compared with the dynamo. Of course the thing that determines how long you make the short circuit is, whether you have little sparking or the effects of self-induction, or the effects of self-induction and no sparking.

Mr. G. Gumpel said: When he first heard of Mr. Snell coming forward to give some remarks on the subject of motors, he thought it the best opportunity of getting information on the most important subject that electrical engineers could bring forward. He believed that every indication pointed to the probability of makers turning their chief attention in the future to the perfecting of motors, and that if we could look into the future of electrical engineering, the next six or eight years would see a great development of the motor; that when we can once burn a cheap material—oxidised coal—at a low temperature, we shall have got over the difficulties of the problem of electric lighting. He thought that the present paper was the first that had been specially applied to the design of electric motors, except Prof. Ayrton and Perry's, seven years ago.

He agreed generally with Mr. Snell's conclusions. Nevertheless, he would be heretical, inasmuch as he proposed to attack the whole system on which those questions were dealt with. The relation between a dynamo and a motor had to be considered. He wholly disagreed with Mr. Snell's treatment of the subject. If there were no generators, but simply electricity and its applications, the question of the electric motors would be attacked altogether differently. He drew an analogy between the dynamo and the air-pump and air-compressor, with the object of showing that the one had the same elements of inefficiency as the other. Seven years ago Prof. Silvanus Thompson, in a paper read before the Society of Arts, introduced his subject with the remark that Clerk Maxwell, just before his death, being asked what was the greatest discovery in the last 25 years, replied, "The reversing of the Gramme dynamo." He (Mr. Gümpel) wrote to one of the papers—*Knowledge*—stating that Clerk Maxwell could not have said such a thing. It was built upon Lenz's law, which was published in *Poggendorf Annalen* in 1834.

Mr. Kilgour suggested that the interest on the cost of motor divided by the number of hours it was worked might be expressed in watts at the current price of electricity. Adding this ordinate to the ordinate representing e.h.p. supplied in Mr. Snell's diagram, this would tend to bring the point of maximum efficiency further to the left, and nearer to the point of maximum output. This point, he thought, might influence the construction of motors in some cases.

Dr. Walmesley: I have little to say, because all my points have been anticipated by one speaker or the other; but I congratulate the society on having such a paper brought before it. It is a great thing for the society, and I congratulate Mr. Snell upon the very admirable paper he has given us. Mr. Snell wishes that I should refer to a point as to the equation dealing with the back E.M.F. The meeting will have gathered from Prof. Ayrton, and know already, that it is not the electrical back E.M.F. Mr. Snell has explained to me that, although it so appeared in his paper, his intention was that it should not be referred to as internal E.M.F. of the armature. If that were so, of course then the efficiency of the motor will be 100 per cent., because the only way in which you can put energy into the motor is by making the current work against a back E.M.F. If, therefore, C is the current—a series motor is referred to in the question—E_m is the real back E.M.F. of the motor, and the total energy put in must be C times E_m, and if that is the brake horse-power you have a highly efficient motor. The way in which I would prefer to write the equation is as follows:

$$\text{Motor}: E_T - C R = E_m = \frac{\text{B.H.P. } 746}{C} + L_m$$

$$\text{Dynamo} \quad E_T + C R = E_d = \frac{\text{B.H.P. } 746}{C} - L_d$$

Mr. W. B. Esson: I should like to ask Prof. Ayrton a question about the Immisch motor, as to whether it was a drum armature or a ring armature?

Prof. Ayrton: A drum armature.

Mr. W. B. Esson: Yes: that seems to me to be rather important. Another question I would ask Prof. Ayrton is: When he sent the current through the machine as a dynamo, was the lead the same amount in a forward direction as it was in a back direction, when he used it as a motor? That also is very important.

Prof. Ayrton: That, and any further questions, I will answer later.

Mr. W. B. Esson: I do not know whether I am in order in saying much now, because I had my turn last time.

The **Chairman**: We shall be very glad to hear anything from you on the subject.

Prof. Ayrton: We shall be delighted to hear more from Mr. Esson, who made such excellent remarks last time.

Mr. W. B. Esson: Well, the first point is about the drum armature. Of course, in a drum armature, the saturation is much less in the core of the armature than it would be in a ring armature, and my experiments were made with a ring armature. In the paper which detailed those experiments, I put in a term for the self-induction, as the expression was meant to be a general one, and, of course, the self-induction becomes very important when you have a low degree of saturation in your armature. Prof. Ayrton, in describing his experiments, says in all cases the E.M.F. of the motor was very much higher than that of the dynamo; but I want to point out that when you take the difference of potential at the terminals of the motor, and deduct from that C R, you are not then measuring the back E.M.F. of the motor; you are sending a current through this motor, and, in doing so, you have to overcome, first, the electrical resistance, C R; secondly, the back E.M.F. of the motor itself; thirdly, the E.M.F. due to self-induction, and therefore you are measuring the E.M.F. of the motor, plus something which depends on self-induction. Come to the dynamo. When you take the difference of potential at the terminals of the dynamo, and add C R, you have not got the E.M.F. of the dynamo, but you have got the E.M.F. minus the term which depends on self-induction. I contend that Prof. Ayrton, in his experiments, has been really measuring the self-induction of the machine, and the difference which he has got—the difference in volts—is equal to twice the E.M.F. due to self-induction. That is on the supposition, mind you, that he uses the same back lead in the motor that he does forward lead in the dynamo. It is a very simple thing to measure this self-induction, and it ought to be measured, then Prof. Ayrton would know exactly how much to credit to this, and how much to credit to the strengthening or weakening of the field. Mr. Snell has added some new figures on the board, and he told me to-night before the discussion was resumed, that he had measured the back E.M.F. in a machine run as a motor and the E.M.F. in the same machine run as a dynamo, getting therefrom the value of the field as shown on the board. I would ask whether that was a drum armature.

Mr. A. T. Snell: A ring armature.

Mr. W. B. Esson: I find that it was not very highly saturated because I have worked it out in C.G.S. units, and the effective magnetism was equal only to 13,720 for the dynamo and 14,602 for the motor. There is only one thing that I have to add, and that is about the compound windings of the Manchester machine. In the dynamo downstairs, that Prof. Ayrton talks of, it may be that the series is about half the shunt. That is a very common proportion; it is the proportion which we have in the Phœnix dynamos, but, of course, the turns of the series wire depend upon a great many things. In our dynamos the series turns on the magnets have generally a fixed relation to the windings on the armature, but they depend upon the turns on the armature, upon the degree of saturation in the field, and upon the self-induction. I have measured the compensating effect, and I have also measured what is required to raise the E.M.F. of the machine. It is a very easy thing to do. You simply take the saturation curve of the machine by separately exciting it, allowing no current to flow through the armature; you mark the position of 100 volts, and see how many ampere-turns are required to raise it to 105. When you have done this you find how many ampere-turns you want on the field-magnets to bring the E.M.F. up from 100 to 105 volts with the full current flowing, and I find that in the Phœnix machine the ampere-turns required to counterbalance the weakening effect are exactly equal to the amount of ampere-turns required to raise the E.M.F.

While I was experimenting on this subject I consulted Mr. Kapp, Mr. Swinburne, Mr. Sellon, and some other of my friends, and in most cases they found that they had about the same effect. The most peculiar instance was furnished by the Victoria dynamo, for there I think the compensating turns were four times the amount required to actually raise the E.M.F. requisite for sending the current through the armature and series wire.

(To be concluded.)

COMPANIES' MEETINGS.

THE EASTERN TELEGRAPH COMPANY, LIMITED.

The thirty-third half-yearly general meeting of the Eastern Telegraph Company, Limited, was held on Thursday, Jan. 24th, at Winchester House, Old Broad-street.

Sir John Pender presided, and, in moving the adoption of the report, stated that the revenue for the six months ended September last had been £310,104, being an increase of £18,839 as compared with the revenue for the corresponding period of 1887. Their holding of shares in the Eastern and South African Telegraph Company had given them an increase of £7,800, the dividend having been at the rate of 12 per cent. per annum as against 8 per cent. last year; and their general traffic, chiefly South African and South American, had given them £10,531 more. The working expenses for the half-year had been

Digitized by Google

£83,332, or £3,396 more. The number of their foreign staff had been increased in order to work the triplicate cable from Porthcurnow to Malta, and extension to Zante, and the duplexing of the same. They had also opened a new station at Cadiz, having put that place in telegraphic connection with Villa Real and Gibraltar. The laying of the new cable from Porthcurnow to Malta and Zante, besides giving the Company greater security and rapidity of working, had diverted to their system a large part of the Greek and Turkish traffic which formerly went *viâ* the Continent. A greater number of messages had been carried in the past half-year than in the corresponding period of the previous year, and the work to be performed by their staff increased year by year. They had carried £5,000 to their reserve fund for maintenance of ships against £4,000 in the previous half year, thus accounting for £1,000 of the total increase in the working expenses. The repairs to cables had cost them £43,075, or £8,973 more. That was always an uncertain item in their accounts. The ships had been busily employed in maintaining the Company's system in a state of efficiency. The increase under this head was in the value of the new cable laid in, the total length being 130 miles against 38 miles in the corresponding period of 1887. A reference to the reserve fund would show that they had applied over £13,000 in reduction of capital expenditure, or in other words, although they had spent over £13,000 in extending and improving their system, the capital expenditure remained at practically the same figure as last time. The 6 per cent. debentures of the Direct Spanish Telegraph Company had been transferred to their reserve fund investments, which stood at £315,494, the total reserves of the Company amounting, after deductions, to £355,676. They paid the usual interim dividend at the rate of 5 per cent. per annum; and after providing for interest on debentures, debenture stock, and preference shares, they were able to carry £36,616 forward, or £7,219 more than in the corresponding period of 1887. When they met six months hence he hoped to have the pleasure of announcing the completion of their West Coast of Africa cable—a work which would not be finished an hour too soon. An enormous traffic was now being carried to the Cape and the Transvaal in connection with the gold speculations, and any interruption to the present cable would be disastrous. With the other cable completed, he fully believed they would be able to meet all the telegraphic requirements of the public. Their system was working thoroughly well, but to keep it in a state of entire efficiency a vast amount of work had to be performed by their ships. Being in the neighbourhood of Suakin, their vessels had given every possible assistance to the British Government while the Egyptian and English troops were in action there, and their help had been thoroughly appreciated. They had maintained their system in a thoroughly efficient state, but what he had told them showed the necessity of duplexing and duplicating the system, without which they could not possibly have carried out the work they had done.

The **Marquis of Tweeddale** seconded the motion.

In reply to remarks by **Captain Goodsall**,

The **Chairman** stated that that gentleman had left the Company's service. The paper mentioned by Captain Goodsall was established by Sir James Anderson and one or two other gentlemen interested in telegraphy, entirely for the benefit of the great system with which they were so closely connected, for the purpose of giving the best scientific opinions upon questions relating to cables. They had never taken one shilling of profit from the paper. It was true that occasionally when any important negotiations were going on he had been abroad, and in connection with such purposes he had used the Company's ships. He had found that negotiations had been far more successful when carried out in person instead of by correspondence. But for their coming into frequent communication with the Great Powers of Europe and elsewhere, he was confident that the Company would not now be occupying the high position it did. Such "excursions" as those referred to by Captain Goodsall were no benefit to himself or Sir James Anderson, while, on the other hand, they involved some sacrifice.

The motion was carried, and resolutions were afterwards passed re-electing the retiring Directors and Auditors.

DIRECT UNITED STATES CABLE COMPANY.

The twenty-third ordinary general meeting of the Direct United States Cable Company, Limited, was held on Friday last, at Winchester House, Old Broad-street.

Sir John Pender presided, and in moving the adoption of the report stated that the revenue for the half-year to December 31, after deducting out-payments, had been £34,188. The working and other expenses, including income tax, but exclusive of the cost of repairs, had been £16,476, leaving a balance of £17,712 as the net profit of the half year. Adding the sum of £6,071 transferred from the reserve fund account for dividend purposes to June 30 (that was, to the end of their last financial year), there was a total of £23,783, out of which two dividends of 2s. each had been paid for the quarters ended June 30 and September 30, leaving a balance of £11,641 on the revenue account. A further interim dividend of 3s. 6d. per share for the quarter ended December 31, being at the rate of 3¼ per cent. per annum, had been declared, and the dividend warrants would be posted that evening. There would then remain a balance of £1,017 to be carried forward. The revenue for the half-year—which included only four months at the shilling rate, the 6d. tariff having been in force up to the end of August—showed an increase of £11,185 over that of the corresponding period of 1887, but no reliable comparison was afforded by these figures, because the 6d. tariff was in force throughout the whole of the six months to December, 1887. The shilling tariff, however, had brought about some reduction in the volume of the traffic, as was naturally to be expected, but the earnings so far had been fairly augmented. The reserve fund account, after being credited with the interest on the investments and the profit on securities realised, and being debited with the outlay on the removal to Halifax and the cost of deep-sea repairs, now stood at £239,206. The special expenditure on the removal, and the deep-sea repairs, ought to be recouped to the reserve fund as soon as convenient. The investments continued, as heretofore, to be worth considerably more than they were stated at in the balance-sheet. With reference to the change in the rate, they had so far not been disappointed in the shilling tariff, though they did not get enough from it to pay a fair dividend. He hoped, however, that people who used the system—and the commerce of the world was now carried on more or less by submarine telegraphy—would get accustomed to the extra sixpence a word, and that the traffic would then go on increasing. They were giving the telegraphing public a fair trial at a very cheap rate, and he hoped that no alteration would be necessary in the future.

Mr. William Ford seconded the motion.

In reply to the remarks of **Mr. Jackson** and **Mr. Guesdon**,

The **Chairman** stated that they did invite tenders for the repair of the cable. They were submitted to their consulting engineers, who reported as to the tender which they ought to accept, and which they did accept There was no comparision between the nature of their late repairs—constituting, perhaps, the most important repairs ever made in a submarine cable—and the ordinary repairs of the short cables.

The motion was adopted.

METROPOLITAN ELECTRIC SUPPLY COMPANY.

An extraordinary general meeting of the Metropolitan Electric Supply Company, Limited, was held on Friday at the offices, Winchester House, Old Broad-street, Sir John Pender in the chair, to confirm the resolution passed at the meeting on the 8th inst., for altering certain clauses of the articles of association.

On the motion of the **Chairman**, seconded by **Mr. J. C. Parkinson**, the resolution was confirmed.

The **Chairman** afterwards stated that they were going on as quickly as they could with their installations. They had one working, and two others were in course of construction. His impression was that they would have more demands on them than they could supply for some time, but there would be no want of energy on their part to meet requirements.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts for the week ended January 25 amounted to £5,435.

Dissolution of Partnership.—Messrs. Rowbottom and Godwin, electrical engineers, &c., of Derby, have dissolved partnership.

Western and Brazilian Telegraph Company.—The receipts of this Company, after deducting the "fifth" payable to the London Platino-Brazilian Company, were £4,550.

Change of Address.—The London office of Messrs. J. G. Statter and Co., Limited, of Alliance Engineering Co., West Drayton, is now at Princes Mansions, 68, Victoria-street, Westminster.

Great Northern Telegraph Company.—Messrs. C. J. Hambro and Son announce the numbers of the Great Northern Telegraph Company's debentures of 1883 (series B) drawn for payment on March 1.

Cuba Submarine Telegraph Company, Limited.—In their report for the half-year ending December 31, this Company state that the gross receipts (including the balance brought forward) amounted to £21,904, and the available balance to £15,508, of which £4,000 has been added to the reserve, increasing that fund to £84,000. The dividend on the preference shares will absorb £3,000, and the Directors recommend a dividend on the ordinary shares at the rate of 9 per cent. per annum, tax free, £1,308 being carried forward.

National Telephone Company, Limited.—The accounts of this Company, made up to December 31, show a gross revenue of £117,726, as compared with £99,563, and the Directors have declared a dividend for the six months ending December 31 last at the rate of 6 per cent. per annum on the first and second preference shares, and an interim dividend at the rate of 4 per cent. per annum (being at the same rate as for the corresponding period) on the ordinary shares, carrying forward £10,399, of which £3,500 is set aside against an outstanding claim. The unaccrued revenue carried forward amounts to £54,385, as against £45,826.

Anglo-American Telegraph Company.—The report of this Company states that the total receipts from the 1st of July to the 31st of December, including the estimated balance of £390 brought forward, are estimated at £131,186, which is, however subject to revision upon settlement of the accounts with the Paris-New York Telegraph Company. The traffic receipts show an increase of £35,352; the total expenses, including repair of cables, etc., amounted to £51,110. Interim dividends of 7s. 6d. per cent. on the ordinary and 15s. per cent on the preferred stocks were paid, and the Directors recommend a final dividend of 15s. per cent. on the ordinary and £1. 10s. per cent. on the preferred stocks, making a total distribution for the year of £1. 12s. 6d. and £3. 5s. respectively, leaving an estimated balance of £1,325 to be carried forward.

German Union Telegraph Trust.—The report of the Directors of the German Union Telegraph and Trust Company for the period ending January 25, 1889—their final report—states that the total receipts during the time amount to £754, which, with a balance of £156 brought forward from the last account, make a total of £910.

Digitized by Google

The expenses for the same period amount to £909. Of this sum £750 is provided by the German Union Company of Berlin. The balance will be handed over to the liquidators. On January 22 an extraordinary general meeting of the Company was held, and voluntary liquidation was resolved upon. The liquidators will have the charge of distributing the assets receivable from Berlin in repayment of capital and interest. A first return of £7. 7s. 6d. per share will be made forthwith, and the balance at the end of April, or in the beginning of May. The liquidators now retire, and the liquidation will be made with all possible despatch.

City of London and Southwark Subway Company.—The report of the Directors of this Company states that, since the date of the last report, continual progress has been made with the underground work throughout the whole line, and so rapidly has it proceeded that in about three months from the present time it is expected that the tunnels—from King William-street to Kennington Oval, a distance of about 2½ miles—will be completed. The construction of the stations is also being actively carried on. The main underground works at the King William-street and Great Dover-street stations are nearly completed, and those at the other four stations are progressing favourably. During the last half-year over 3,800 yards of tunnelling have been completed, a speed unparalleled in work of a similar character. In accordance with resolutions passed by the shareholders at the last half-yearly meeting, the Directors have devoted a large amount of attention to the question of the best method of electrical haulage, suitable for efficiently working the traffic upon this line, and they invited proposals from several of the chief electrical manufacturers. After a very exhaustive examination into the details of the several different proposals, the Directors, acting under the advice of the Company's engineers, and aided by the valuable assistance of Mr. C. E. Spagnoletti, an experienced electrical engineer, have entered into a contract for the installation of the necessary machinery and plant with the well-known engineers, Messrs. Mather and Platt, of Manchester, the electrical department of whose business is under the immediate direction of Dr. Edward Hopkinson, who has had exceptional experience in electric traction. It is with much pleasure that the Directors are enabled to report the satisfactory conclusion of their investigations upon this most important subject. The contractors have undertaken to provide the power necessary to run a three minutes' service from each station at a greater average speed than that now attained on the Inner Circle of the Metropolitan Railways, and they also guarantee for a period of two years the cost per train mile at a considerably lower rate than if steam locomotives were used. The Directors have the fullest confidence that these provisions will be duly carried out and will result in the establishment of a system of underground conveyance for the metropolis of an exceptionally convenient character, and worked at such a cost as will give a satisfactory return to the shareholders. The electrical power provided includes also the lighting of the trains and stations. The Company have now purchased all the land and property required for the construction of the works, and have also acquired a piece of land exceeding 1½ acres in extent at Stockwell on which the machinery for working the line, as well as the carriage sheds and workshops can be conveniently erected. The Directors who retire by rotation are Messrs. Sampson Hanbury and C. G. Mott, who are eligible for re-election. The auditors likewise offer themselves for re-election.

PROVISIONAL PATENTS, 1889.

JANUARY 21.

1056. **Improved electrical storage battery.** Thomas Pease, 3, Kimberley-street, Liverpool.

1057. **Improvements in electric date and time hand stamps.** Charles Adams-Randall, 15, Montpelier-square, Brompton, London.

1058. **Improved phonographic system and apparatus for recording and reproducing articulate speech and other sounds.** Charles Adams-Randall, 15, Montpelier-square, Brompton, London.

1101. **Improvements in and relating to underground mains for electric conductors.** William Lowrie and Charles James Hall, 433, Strand, London, W.C.

1102. **Improvements in or relating to safety fuses and boxes therefor.** William Lowrie and Charles James Hall, 433, Strand, London, W.C.

1103. **Improved system of distributing pipes, or conduits, for containing the supply conductors for electric lighting.** William Lowrie and Charles James Hall, 433, Strand, London, W.C. (Complete specification.)

1112. **Improvements in simultaneous telephony and telegraphy.** Eugene Gwosdeff, 6, Bream's-buildings, London. (Complete specification.)

1113. **Improvements in long-distance telephony.** Eugene Gwosdeff, 6, Bream's-buildings, London. (Complete specification.)

JANUARY 22.

1118. **Improvements in apparatus for automatically switching loop circuits out of or into the main electric circuits.** Elmer Ambrose Sperry, 1, Quality-court, Chancery-lane, W.C. (Complete specification.)

1162. **Improvements in and relating to electric governors for steam or other motive-power engines.** Rankin Kennedy, 96, Buchanan-street, Glasgow. (Complete specification.)

1166. **Improved method of, and means for, testing the insulation of electric conductors.** William Lowrie and Charles James Hall, 433, Strand, London, W.C.

1167. **Improvements in and relating to switches and switch connections for electric circuits.** William Lowrie and Charles James Hall, 433, Strand, London, W.C.

1168. **Improvements in electric current switches.** William Lowrie and Charles James Hall, 433, Strand, London, W.C.

1169. **An automatic electrical machine for the delivery of prepaid articles.** George Evan Rutter, 26, Parkholme-road, Dalston, London, N.

1190. **Improved means in connection with electric current transformers for regulating the electro motive force in the working circuit.** Laurence, Paris, and Scott, Limited, and William Harding Scott, 47, Lincoln's-inn-fields, London.

JANUARY 23.

1216. **Automatic contact maker and breaker for electrical circuits.** George Edwin Fletcher, 93, Chatham-street, Edgeley, Stockport.

1229. **Improvements in adjustable suspending devices for electric incandescence lamps.** William Robert Rawlings and John Joseph Rawlings, 70, Market-street, Manchester.

1236. **Improvements in underground conduits or channels for electrical conductors.** Benjamin Verity, 55 and 56, Chancery-lane, London.

JANUARY 24.

1311. **Improvements in raising, and lowering, and extending, applicable to table pillars, table lamps, electric pillars, and to other purposes.** Harry Christie Harrold, Robert Jenkins, and Samuel Johnson, 30 and 31, St. Swithin's-lane, London.

1313. **Improvements in bleaching paper pulp and vegetable fibres by electrolysis.** Emile Marie Hippolyte Andreoli, 62, Loughborough-park, Brixton, S.W., Surrey. (Complete specification.)

1341. **An improved electrical indicator.** Charles Wells, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex.

1343. **Improvements in instruments for measuring electricity.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 55 and 56, Chancery-lane, London. (Complete specification.)

JANUARY 25.

1358. **Improvements in electrical coin-counting, valueing, and checking machines.** James Gilbert Cumming, 7, Union-street, Edinburgh.

1401. **Improved mode of generating electricity by dynamo-electric machines.** Isaac Tillman Dyer, Peter Fish, and Rebecca Charlotte Fish, 76, Chancery-lane, London, W.C. (Complete specification.)

1420. **Improvements in secondary batteries.** Frank King, 47, Lincoln's-inn-fields, London.

1421. **New and useful improvements in voltaic electric belts employed as medicinal agents.** George Allan Sykes, 30, Romberg-road, Upper Tooting, London, S.W. (Complete specification.)

JANUARY 26.

1454. **Electric meters.** Henry Francis Joel, 44, Lavender-grove, Dalston, London, E.

1456. **Improvements in electric traction.** Vittorio Giovanni Lironi, Walnut Tree House, High-road, Leytonstone, Essex.

1460. **Improvements in secondary battery plates, elements, or supports.** John Scudamore Sellon, 47, Lincoln's-inn-fields, London.

SPECIFICATIONS PUBLISHED.

1888.

2707. **Friction dynamometers.** Coupe. 8d.
2772. **Electrical safety appliances.** Hedges. 8d.
2933. **Regulating dynamos.** Haddan. (Hill.) 8d.
3223. **Secondary batteries.** Kingsland. 6d.
17,008. **Dynamo machines.** Schiödt. 6d.
17,063. **Electric spray-preducing apparatus.** Huguet. 6d.

NOTES.

Moscow.—A large central station is being opened in Moscow.

Mysore.—An electrician from England is now at Mysore fitting up electric light in the Maharajah's palace.

Arc Lamps.—The Thomson-Houston Company sold 18,500 arc lamps during the last year to all parts of the world.

Julien Company.—The Julien Company will shortly have 12 storage cars running on the Fourth-avenue road, New York.

Edison Transformer.—Edison is said to be at work on a transformer which is to be the ideal method of distributing energy over large areas.

Strand.—An influential memorial has been presented to the Vestry of St. Martin's-in-the-Fields urging them to light the Strand with electric light.

Royal Institution.—On Friday, February 8, at 9 p.m., the Royal Institution will meet to hear Sir William Thomson on "Electrostatic Measurement."

Companies in 1888.—The *Investors' Guardian* gives the following statistics of electrical companies formed in 1888: Electric, £3,026,500; Telephone, £20,240,000.

Smoking Concert.—The fourth smoking concert of the City Guilds Old Students will take place at the Manchester Hotel, Aldersgate-street, on Saturday, February 23, at 7.30 p.m.

Printing by Electricity.—The presses of the *Iowa State Register* of Des Moines, U.S., are worked by electricity. The editor says it is a good, safe and cheap power for the purpose.

National Telephone Company.—The nomination of Mr. J. B. Morgan, managing director of the United Telephone Company, has been withdrawn from the Board of the National Telephone Company.

Electric Launch for the Sultan.—A launch, with a swan's-neck prow, is now being built at Richmond for the Sultan, which will be driven by electricity. It is to be delivered at Constantinople in April.

Kensington.—Representatives of the several electric light companies met the Kensington Vestry at a special meeting on Wednesday to explain their systems. The report of the committee was adopted, one of the chief provisions being that no overhead wires were to be used.

Arc Lighting in Paris.—Paris will be brilliant with arc lights during the present year. A sum of 200,000f. has been voted for lighting the Avenue de l'Opera and the principal boulevards, from the Madeleine to the Boulevarde de Sebastopol, with arc lamps during the period of the Exhibition.

Windsor Castle.—After several trials, it has at length been decided to use the electric light at Windsor Castle. The machinery at the palace is now in working order, and a portion of the corridor will, it is understood, be illuminated by a series of incandescent lamps on the return of the Court from Osborne.

Spanish Electrical Journal.—New electrical papers are springing up as the field increases, and the late exhibition in Barcelona seems productive of result in this direction. We have this week to acknowledge the receipt of a copy of *Anales de la Electricidad*, published in Barcelona, and devoted to electrical subjects.

Wolverhampton.—We hear that a company is being formed for supplying electric light in Wolverhampton. The gentlemen who are promoting the scheme, it is said, hold positions of considerable influence in the town and district. It is understood that the necessary plant will be supplied by Messrs. Elwell-Parker.

Speed on Electric Railways.—The cars on the Sprague railway with overhead wire at St. Joseph, Mo., have sometimes been run at as high a speed as 25 miles an hour. This is approximating to the speed of a Continental railway express, so that we may evidently soon hope to see real railways work electrically.

Engines at the Louvre.—The Paris authorities have just awoke to the danger likely to occur from the engines and furnaces for the electric light which have been allowed to be erected in immediate proximity to the valuable collection of pictures in the Louvre. The whole of the engines are now ordered to be removed.

Folkestone and Dover Telephone.—The business done over the wire of the South of England Telephone Company between Folkestone and Dover proves how very great a need there existed for cheap and rapid communication. Since April last, when the line was opened, no less than 54,165 messages were transmitted up to the close of last year.

Meters Wanted for Bradford.—The installation at Bradford now approaching completion, the Corporation desire to adopt some reliable meter for measuring the sale of their currents. In another column will be found an advertisement asking companies or persons who have such meters for disposal to communicate with Mr. J. N. Shoolbred, the engineer to the Corporation.

Institution of Electrical Engineers.—The next meeting of the Institution will be on February 14, at 8 p.m., when the adjourned discussion of Prof. Jamieson's paper on "Insulation Resistance of Electric Lighting Plants" will be concluded. A paper will be read "On Certain Phenomena Connected with Imperfect Earth on Telegraph Circuits," by A. E. Kennelly, associate.

Bingley Hall Exhibition.—Our readers will see from the advertisement that the promoters of the Electrical Exhibition at Bingley Hall, Birmingham, are pressing forward with their arrangements. The whole of the power is intended to be supplied electrically, and all departments of electric industry will be represented. The committee are now prepared to receive applications from intending exhibitors.

Self-Exciting Alternating Dynamos. — Both Thomson-Houston and Ganz and Co. now make alternate-current dynamos which are self exciting. The means adopted is simply that one of the armature coils is compound-wound and connected to a separate small commutator on the shaft which commutes the current into one direction; the current from this is then used to excite the field-magnets of the machine in the ordinary way.

Gas v. Electricity.—The Imperial Continental Gas Association of Vienna, while adding to their power of light supply by the central electric light station at Schenkenstrasse, are also, it appears, increasing their gas supply by putting down a new gas works. The gasholder is to be, moreover, the largest upon the Continent. This looks as

Digitized by Google

if the Vienna company did not think their gas business was likely to ultimately suffer by the electric competition.

Birmingham.—At a meeting of the City Council on Tuesday the General Purpose Committee reported that they had considered Messrs. Chamberlain and Hookham's application for a provisional order for electric lighting, and recommended the Council to withhold consent except for a restricted area. An amendment was proposed by Alderman Powell Williams, M.P., that the Council should consent to the application for an order to light the whole of the city. Ultimately the amendment was withdrawn, and the report agreed to without a division.

Oporto.—Tenders were to be received by the Municipal Board of Oporto for lighting the town with gas up to the 7th inst. Parties tendering will have to deposit a sum of 10,000 milreis, which is to be raised to 50,000 milreis when the contract is finally adjudicated. The municipality engages to use only gas supplied by concessionaires during fifteen years, and to give them the preference, if after that period it should be decided to introduce electric lighting. At the expiration of the concession all the plant is to be delivered gratuitously to the municipality.

Small Portable Testing Set.—A new and very light portable set, designed by F. B. Badt, and manufactured by the Western Electric Company, Chicago, is described and illustrated in the *Western Electrician.* It is a little under six inches long by four deep and three inches wide, over all, and weighs 1lb. 15oz., including cell and galvanometer. The box contains a small dry cell, a detector galvanometer of 200 ohms resistance, contact key, binding posts and wires. The small weight and the use of a dry cell allow it to be carried in the pocket or tool bag, and will make this set very useful to linemen.

Australasian Electric Light Company.—The reconstruction of the Australasian Company has been attempted on terms that give call for little more expenditure (4s. 3d. per share) to that of winding up, with a prospect in the former case of possibility of a profit. The patents held by the company will consist of those of Swan-Edison, Elwell-Parker, Zipernowski-Deri, and others, and give a practical monopoly of electrical business on any large scale in the Australasian colonies. Controlling these patents in the colony, if this company cannot do the work, they maintain at least no one else can do so without their con sent.

A New Secondary Couple.—We hear from a gentleman who has had some experience with lead accumulators, and has been experimenting lately with other forms, that he has discovered a new secondary couple, giving very good results. The charge of one hour was discharged in 20 minutes after only three or four chargings; and the E.M.F. on open circuit is given as 2·60 volts. The elements are metallic, but not lead, and, as far as the inventor knows, quite original. The experiment is only upon a very small scale, but if any of our readers are interested in the matter we shall be happy to put them into communication with the experimenter.

Swinton Electric Bells.—Mr. Campbell Swinton, who has lately moved into new offices next door to Drake and Gorham, 2, Princes-mansions, has some new and very useful modifications of his electromagnetic bells. He showed us the other day a very compact set, enclosed in polished box, with a single handle, with press-knob projecting from the interior, which rings one single, clear stroke of the bell to every depression of the knob. This bell, without battery or solution to get out of order, should prove extremely useful to stand on an office table and ring in the next room, or to a factory, and also for railway or ship signalling, and for all requirements of this description.

Electric Date Stamp.—An invention for affixing the exact time and date to important documents, telegrams, etc., is being brought out by the Electric Date and Time Stamp Company, Limited, of 19, St. Swithin's-lane, E.C. The box contains battery and clock, and a stamp with the name of the user and any other lettering desired, and has a space for the date and time, which is automatically altered by electricity by the motion of the clock. The stamp is favourably reported upon by Mr. C. P. Spagnoletti and Mr. D. K. Clark, M.I.C.E., reports from whom can be seen at the offices of the company, where the stamp can also be seen in operation. The apparatus is installed and kept in working order on yearly rental.

Lugo's Storage Battery.—Dr. Lugo, of Chicago, has invented a new form of storage battery, in which the oxygen and hydrogen gases evolved are stored mechanically without chemical combination. The electrodes are of finely divided or allotropic lead, each atom of which is coated or completely covered with soft or spongy copper. The material is, therefore, not oxidisable under influence of the charging current. It is packed round conducting plates and immersed in electrolytic solution. In charging, the gases accumulate around the atoms, which act as nuclei. It appears to be an actual storage battery, in the sense that something is stored—namely, the gases. It is claimed as a new departure in the manufacture of storage cells.

A Fever Alarm Thermometer.—Mr. Wilberforce Arnold, J.P., fellow of the Medical Society of London, sends the following to the *Pall Mall Gazette* from Belfast: "A watch-shaped, or other suitable clinical thermometer, could be fixed in the axilla, etc., as easily as the smallest splint. Electrical connections should lead to the sounding of an alarm-bell in some suitable nurse's or other apartment in hospitals and sick homes, giving instant warning to the watchers of any dangerous rise or fall in the patient's temperature, and the calling of physicians or other help without an instant's loss of invaluable time. This would in every country and in all climates be the means of saving many lives every year and throughout all time."

Swansea.—The question of electric lighting is still agitating Swansea, and it has been advocated that the Corporation should purchase the existing gas works, and erect an electric light plant on the same site, so that the Corporation could supply from one station and under one control either gas or electricity. It is suggested that, no doubt, much of the engine-power at present in use by the gas company could be used for both purposes. The Corporation propose, it is said, to use a site cleared at great expense for artisans' dwellings, and the question is raised whether the Corporation would be justified in using such valuable land. If the site of the gas works were used, both gas and electricity might be supplied from the same site, as in the manner of the Vienna Gas Association.

"Everybody's Pocket Cyclopædia."—A third edition of 50,000 of *Everybody's Pocket Cyclopædia of Things Worth Knowing,* price 6d., has been issued by Messrs. Saxon and Co., Bouverie-street, a copy of which has been sent to us. It contains an immense amount of useful

Digitized by Google

memoranda and information compressed in small size, and seems to be most eagerly bought up. In the last edition sixteen pages of nicely-printed small coloured maps of the world are added. Some interesting telegraph statistics of the world are given, but we might suggest that in a further edition some really reliable and useful, but popular information with regard to electric lighting—the influx of which into "everybody's" home is now imminent—might prove more interesting to the public generally than statistics of telegraphs.

Islington.—A special meeting of the St. Luke's (Islington) Vestry was held on Tuesday afternoon, under the presidency of Mr. Churchwarden Blake, for the purpose of considering the terms of the draft provisional order of the London Electric Light Corporation. The Parliamentary and Improvement Committee submitted recommendations favouring the scheme upon certain conditions being observed. They were that the company should fully satisfy the Vestry as to its competency to undertake the work they proposed to carry out; and they should deposit a certain sum of money with the Vestry to provide for the reinstatement of any of the foot or road ways which might be opened and not properly relaid. The committee also advised that steps should be taken to secure distributing mains being laid at the sides of streets. The adoption of the foregoing recommendations was agreed to unanimously.

Exhibition of Meteorological Instruments.—The Council of the Royal Meteorological Society have arranged to hold at 25, Great George-street, Westminster (by permission of the Council of the Institution of Civil Engineers), on March 19th to 22nd inst., an exhibition of instruments connected with atmospheric physics invented during the last ten years, especially those used for actinic and solar radiation observations. The Exhibition Committee invite the co-operation of those interested, as they are anxious to obtain as large a collection as possible of such instruments, etc. New meteorological instruments or apparatus invented or first constructed since last March will also be shown, as well as photographs and drawings possessing meteorological interest. Lists of the articles intended to be contributed, with space required, should be sent in not later than March 1st to Mr. William Marriott, 30, Great George-street, Westminster.

Certificates of the School of Electrical Engineering.—In consequence of the recent reorganisation of the advanced instruction of the School of Electrical Engineers, Princes-street, Hanover-square, which is now under the charge of Mr. Charles Capito, M.I.M.E., the managers recently requested Mr. Gisbert Kapp to undertake the examination of the advanced class. One day was devoted by him to an examination in practical work, such as engine-running, boiler-firing, dynamo and lamp management, joint-making, etc., and a second to papers in mechanical and electrical engineering. Out of seven students examined, three were awarded the certificate of the school, Messrs. Hawkins, Rowlett, and Graves, the average percentage of marks gained by them being respectively 87·3, 78·8, and 65·8. A minimum of 70 per cent. in the practical work, and 60 per cent. in the two papers is a necessary condition of obtaining the certificate. As the result of former examinations, Mr. Fletcher has also recently gained the certificate.

Albion T. Snell on Motors.—M. Hospitalier, in *L'Electricien*, gives some attention to the very interesting paper written by Mr. Snell for the Old Students' Association, intending, he says, to give a complete *résumé* of this paper, "for in this work are found indications on the construction of dynamos not less useful than those which fill the work of Mr. Gisbert Kapp, on the construction of dynamos. Unfortunately, however," M. Hospitalier remarks, "scorning the C.G.S. system and the metric system (as all good Englishmen do, with few exceptions), Mr. Snell gives all the factors of his calculations in inches, pounds, and horse-power: we shall be therefore obliged to do once again, as we have already done for Mr. Kapp to a whole series of complex calculations—to reduce the calculations of the author to C.G.S. units, and the practical units derived therefrom. We trust the author will pardon us rendering more international a study which, under the original form, seems to be specially reserved for John Bull and Cousin Jonathan."

The Centenary of Ohm.—In view of the near approach of the hundredth anniversary of the birth of George Simon Ohm, which took place on March 16, 1789, a meeting was held last week in the meeting room of the Royal Society, under the presidency of the Right Hon. Lord Rayleigh, secretary of the Royal Society, for the purpose of appointing a committee to co-operate with the committee formed in Germany to promote the erection in Munich of a statue to the great physicist, to whom the science of acoustics owes no less than does that of electricity. In the course of the meeting the following gentlemen were selected to act on the English committee: Sir F. Abel, D. Atkinson, Mr. Vernon Boys, Mr. Conrad Cooke, Professors Ewing, Fitzgerald, Fleming, G. Carey Foster, Mr. Glazebrook, Prof. D. E. Hughes, Mr. Norman Lockyer, Professors Hugo Müller, John Perry, Mr. W. H. Preece, Lord Rayleigh, Professors Reinold Rücker, Stokes (President of the Royal Society), Mr. Swinburne, Sir William Thomson, and Prof. S. P. Thompson. Lord Rayleigh was elected president, Prof. Hugo Müller treasurer; and Prof. G. Carey Foster, of University College, London, and Prof. John Perry, of the Finsbury Technical College, undertook to perform the duties of secretaries, and to receive subscriptions.

Telephone in the West of England.—The trunk telephone line between Cheltenham and Gloucester has been formally opened by the Western Counties and South Wales Telephone Company, and telephonic communication has thereby been established between Cheltenham and Gloucester, Bristol, Bath, and other large towns in the West and South of England, and also with Cardiff and other provincial towns in South Wales. In Swansea the fullest and largest benefits of telephony are within reach of people. Anyone can go to the company's call offices, and can hold communication, on payment of a fee of 2d., with any subscriber who may be attached. Not only so, but, on arrangement beforehand—that is to say, by sending a halfpenny post-card—two persons, say one in Newport and another in Swansea, can arrange to meet at a certain fixed hour at one of the call offices in each town, and there, for 2d. each, they can hold a long conversation. The same arrangement can be brought about within an hour by the despatch of a sixpenny telegram. These facilities will evidently lead to much business advantage when they become generally known. The local telephone company now goes further, and is prepared to issue to all subscribers to the Telephone Exchange a free pass (on payment of a returnable deposit of

Digitized by Google

5s.) which will enable the holder to make use of any of these public call offices without payment of the 2d. fee. Telephone facilities are wonderfully increasing in the provinces.

Lambeth.—A report was read from the Electric Lighting Committee with respect to the applications made by the London Electric Supply Corporation and the Metropolitan Electric Supply Company for provisional orders for Lambeth under the Electric Lighting Acts. The committee recommended the Vestry to oppose both the applications, with the view of obtaining from one or other of such companies, or from some other company or contractor, such protective clauses and provisions as the committee, under the advice of the officers of the Vestry, might consider necessary in the interests of the parish. Mr. Andrew, in moving the adoption of the report, said the committee were ready to do everything to further the progress of the electric light, but at the same time they desired to prevent the creation of another monopoly. Mr. Penman asked whether it would not be better for the Vestry to apply for a license and then farm it out to some company. Mr. Andrew replied that the Board of Trade would not grant a license unless they were assured that the Vestry intended to carry it out. It was suggested that clauses should be inserted as follows: (*a*) "That the company should be bound to lay down mains and supply electricity in certain trunk streets within a definite time, to be settled by the order, and in side streets when required either by the Vestry or by a specified number of owners or occupiers in such streets, and that on the breach by the company of this condition the order should be cancelled; (*b*) that the cost of laying all mains in the public streets should be borne by the company; and (*c*) that all wires should be laid underground unless with the consent of the Vestry." After some discussion the Vestry adopted the committee's recommendations.

Prize Competition for Measuring Instruments. A German electrician, Herr F. Zöpke, has addressed a circular to his clients, says *Industries*, calling their attention to the importance of prolonging the life of lamps in installations by carefully limiting the pressure to that value for which the lamps are intended. He suggests that overrunning may occasionally be due to carelessness on the part of the driver, but is more often caused by wrong indication of the voltmeter. To detect a change in the calibration of instruments, he suggests that every installation should be provided with one standard voltmeter, to be carefully kept in the owner's office, and used occasionally for controlling the engine-room voltmeter, or that a standard voltmeter, provided with an alarm bell, which will ring when the right pressure is exceeded, should be placed in some convenient place. He offers such standard instruments at an annual rental of £1 and £2 respectively. As, however, the adoption of his suggestion would only mitigate the evil, by facilitating the detection of errors in the ordinary instruments, but not completely cure it, he has offered a prize of £50 for a better solution of this question. For this purpose Herr F. Zöpke has requested the Berlin Technical College to issue the following problems for this competition: "(1) The construction of a voltmeter perfectly unaffected by changes of temperature or changes of the material entering in its construction; (2) if the solution of problem 1 be found impossible, the construction of a simple registering apparatus which can be added to a voltmeter in order to record the exact time during which the normal pressure has been exceeded." It is not stated whether foreign competitors are to be excluded; but as no mention is made of restricting this competition to Germans, it may be taken that electricians of any country may compete.

Liverpool Tramways.—There seems to be a good opening in Liverpool at the present for electrical tramways, and if our electrical engineers do not bungle, the latest and best method of street traction should be speedily adopted there. The Liverpool Tramways Company have made up their minds to get rid of horses and substitute mechanical traction of some kind, but of the kind the company do not yet seem to have determined—the company's report even mentioning engines worked by regulated explosives. Steam will not do because of the narrowness of the streets; compressed air and cables are too dear. Lord Bury has written to the papers with reference to this report, pointing out that electricity is now in a far better position than compressed air or cables, saying that after preliminary experiments they had laid down a temporary plant for purposes of demonstration on one of the branches of the North Metropolitan Tramway Company, where their exhibition carriage has been running with complete success for many months past. Now that this phase is over, the temporary plant has been removed, large and powerful stationary engines and dynamos are rapidly being erected on the spot where it stood, and five handsome cars, completed and wired for the reception of the electrical accumulators and motors, stand ready in the Leytonstone works of the North Metropolitan Company's car manufactory, waiting only till engines and boilers, which are on the spot at Barking, can be placed in position. A fortnight or three weeks will see the whole at work, and a complete service of electric cars will take the place of horses on the Barking section of the North Metropolitan Tramway Company. "The Electric Traction Company," continues Lord Bury in his letter to the *Daily News*, "and their electrical friends, the firm of Immisch and Co. (between whom and the Electric Traction Company a considerable solidarity of interests exists) have already at work, with good commercial results, pumping engines in mines where pumping was before expensive and unsatisfactory. They have electric launches running, and more in construction, and theirs is the only motor which has made telpherage a commercial success. In fact, in the wide field of electric traction they have acquired a position which permits me now to discard the reserve which during the experimental stage we were anxious to maintain. We hope that you and the directors of the Liverpool Tramways Company, and others who share with you the anxiety to see electric traction on a sound system, commercially profitable, will come and see our system at work on the North Metropolitan Company's line from Barking to Canning Town."

Light without Heat.—The recent researches of Hertz and Dr. Oliver Lodge into the possibility of production of light without heat may yet result in practical outcome in our own times. At least, there is already a claimant for the first honours in this department. Mr. A. B. Worth, of Greenport, Long Island, U.S., writing to the *Electrical World*, with reference to the subject of obtaining light without accompanying heat, says: "I am induced, as a matter of protection, to place before the public my own claims upon the subject. My work in this field was commenced in the latter part of 1884, and

Digitized by Google

especially early in 1885, and has been continued, in one form or another, up to the present date. It is quite evident that when an electric current is passed through a filament a part of its energy appears in the form of useful light, and the remaining, and larger, part in the form of heat. But as light can exist and perform its various luminous, chemical, and electrical effects without the aid of heat, the latter, when emitted from the filament, is a total loss of electric energy. I have at present two or three methods, with their modifications in a more or less completed form, for overcoming this difficulty, and it is the expectation in the near future to produce a lamp the illuminating parts of which can be handled with impunity, while the same is giving forth a brilliant and soft light. Perfection will be reached when the filament will remain absolutely cold while under full action. A modified source of electricity is used in some cases with these lamps, as well as other sources of energy. The filaments are made in various shapes, some of them not at all resembling those we are accustomed to see, while in a few of the improved lamps none are used. The colour of the light emitted can be varied through the entire spectrum in certain forms of lamps. In his late address Prof. Brackett mentioned the idea of casting polarised rays of light upon the proper conductor, and causing an intermittency or alternation of an electric current. Now this is almost exactly the method shown by my drawings, and described in my papers of 1884 and 1885, except that the idea is there shown more developed. Some interesting facts in connection with this will be brought out sooner or later. A large quantity of accessory apparatus and different methods have been devised which necessarily cannot be mentioned here. Finally, I would like to put on record the fact that I have at least four distinct, and what it is thought to be practical, methods of generating electricity otherwise than by dynamos. The object of writing the above is as a means of protection, both from previous and future investigators. Progress has been greatly hindered from the beginning, and is at present, from the lack of funds necessary to perfect and introduce work of such new character and large dimensions, otherwise commercial results might possibly have been obtained about one year ago."

City Lighting.—The new Commission of Sewers was opened in state on Tuesday. Mr. George Manners was unanimously elected to the chair. The Streets Committee brought up a report on the subject of electric lighting, submitting draft conditions with a view to advertising for tenders. The report suggested that the main thoroughfares and public streets of the entire area of the City should be lighted by electricity, and, for convenience, divided into three districts, for all or any of which the contractors should be at liberty to tender. The first district comprises the area bounded on the north by the City boundary, on the east by Aldersgate-street, on the south by the Victoria-embankment, and on the west by the City boundary. The second is the central part of the City, and the third the eastern district. The contractors would be granted the exclusive right of supplying electricity for private purposes within their respective districts, but there were provisions regulating the amount to be charged to private consumers and for the division of profits by the reduction of charges after a dividend of 10 per cent. per annum was earned. The discussion of the report was adjourned. We believe we are correct when we state that the new Commission is animated with an active desire to deal with the matter at once, and that we may shortly look forward to a considerable "boom" in electric arc lighting in the City. In these desires the Commission have most people's hearty support. London is yet the most backward of all the capitals of Europe in its public lighting, but now we are going to stir, we trust the stir will be a satisfactory one in all respects. The area of the City which is to be lighted is as follows: District No. 1, West District, comprising the area bounded on the north by the City boundary, on the east by Aldersgate-street, St. Martin's-le-Grand, St. Paul's-churchyard (north side), Creed-lane, and St. Andrew's-hill, and thence along Queen Victoria-street to Blackfriars Bridge. On the south by the Victoria Embankment, and on the west by the City boundary. No. 2, Central District, and comprising the area bounded on the north by the City boundary, on the east by Finsbury-pavement, Moorgate-street, Princes-street, thence across Mansion House-street, along Walbrook and Dowgate-hill; on the south by the River Thames, and on the west by part of Upper Thames-street, St. Andrew's-hill, Creed-lane, St. Paul's-churchyard (north side), St. Martin's-le-Grand, and Aldersgate-street. No. 3, East District, comprising the area bounded on the north and east sides by the City boundary, on the south side by the River Thames, and on the west side by Dowgate-hill, Walbrook, Princes-street, Moorgate street, and Finsbury-pavement. The whole of the main thoroughfares in each district are to be lighted, and the following is a list of those thoroughfares: District No. 1 (west)—Holborn, Holborn-viaduct, Newgate-street, Charterhouse-street, King-street, Long-lane, Snow-hill, Chancery-lane, Fetter-lane, St. Andrew-street, Shoe-lane, St. Bride-street, Farringdon-street, New Bridge-street, Old Bailey, Fleet-street, Ludgate-hill, St. Paul's-churchyard (north side), District No. 2. (central)—Barbican, Beech-street, Fore-street, London-wall, part of (west of Moorgate-street), Gresham-street, Cheapside, Poultry, Watling-street, Cannon-street, part of (west of Dowgate-hill), Queen Victoria-street, Upper Thames-street (west of Dowgate-hill), Aldersgate-street, St. Martin's-le-Grand, St. Paul's-churchyard (south and east sides), Wood-street, King-street, Queen-street, Cripplegate-buildings, Milk-street, Aldermanbury, and Aldermanbury-postern, Coleman-street, Basinghall-street. District No. 3 (east)—Liverpool-street, Houndsditch, London-wall (east of Moorgate-street), Old and New Broad-streets, Bishopsgate-street Within and Without, Lothbury, Threadneedle-street, Cornhill, Leadenhall-street, Lombard-street, Fenchurch-street, Aldgate, Aldgate High-street, Gracechurch-street, Mansion House-street, King William-street, Cannon-street (part of, east of Dowgate-hill), Eastcheap, Great Tower-street, Upper Thames-street (east of Dowgate-hill), Lower Thames-street, Arthur-street East, Minories, Princes-street, Moorgate-street, Finsbury-pavement, Arthur-street West, St. Mary-axe. So far as the Commissioners are able to do so, they will grant to the contractor the exclusive right of supplying electricity for private purposes within the district during the term of the contract. The contractor will be required to supply electricity to any owner or occupier of any premises within a distance of 25 yards of mains, provided the owner or occupier enters into a fair agreement to defray or divide the cost of the service main, and to pay for the supply of the electricity. The contractor can charge the consumer for the amount of electricity supplied, either (1) by meter or (2) by agreement.

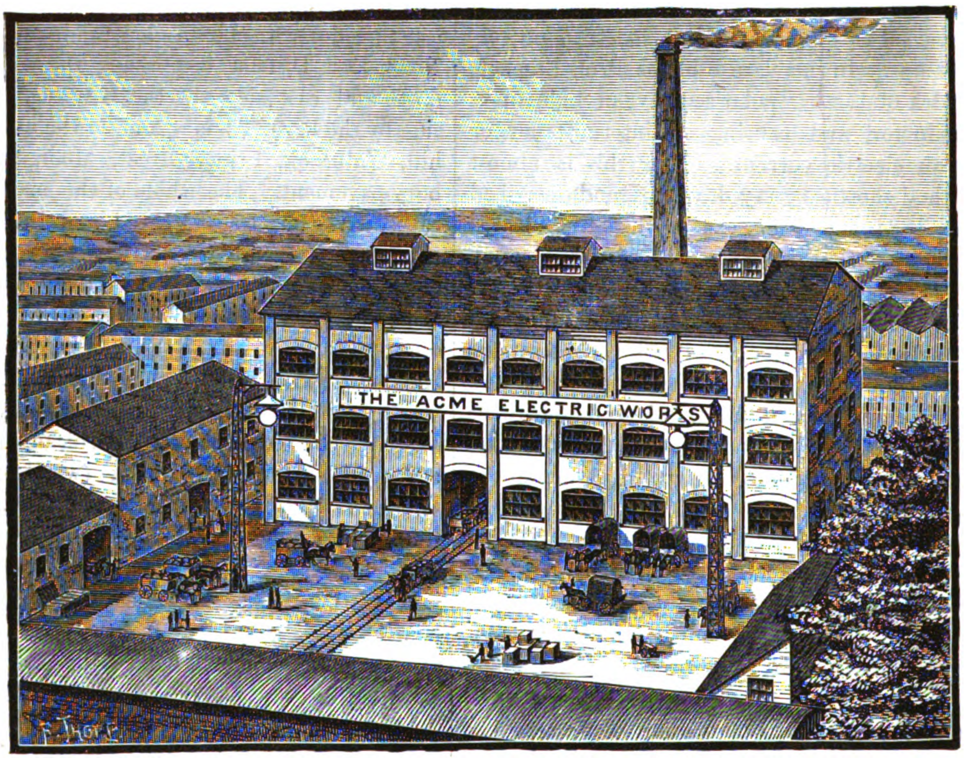
ELECTRICAL ENGINEERS.—V.

THE ACME ELECTRIC WORKS.

The firms of electrical engineers we have hitherto described have either been those formed at the beginning of the period of electric lighting activity, who have had laboriously to struggle through the days of depression and early experiment, or those who were already fully-formed companies who have taken up the more modern development of electrical engineering as a branch of their other electrical or engineering work. The Acme Electric Works, however, is an example of the sudden attainment of business success, due, at first, to the manufacture of a thoroughly good speciality, and carried forward by the constant and increasing demand for electrical apparatus and fittings on all sides consequent on the rebound of the electric lighting industry into good financial activity.

The Acme Electric Works are situated in Ferdinand-street, Kentish Town, near the works long occupied by Messrs. Immisch and Co., and are best reached by the North London Railway from Broad-street to Kentish Town station, which is within three minutes' of the works. Mr. Arthur C. Cockburn, A.I.E.E., who has the management of these works, was for some considerable time demonstrator to Prof. Ayrton, and afterwards to Prof. Sylvanus P. Thompson, at the Finsbury Technical College. It was here he made some accurate experiments on the fusing point of wires, specially with reference to the employment of electric cut-outs, the results of which he embodied in new forms of cut-out with loaded fusible wire, which he patented, and they were brought before the electrical world in the well-known paper before the Society of Telegraph Engineers. The success attained was immediate; large orders flowed in, and Mr. Cockburn relinquished his professional post to embark in the more lucrative business of manufacturing. A new form of quick-break switch was also devised by him in conjunction with Mr. Thomas, and arrangements were made by which these specialities should be manufactured, together with other electrical apparatus and instruments, at the Acme Electric Works, then situated in Tabernacle-street, Finsbury. The requirements of the business speedily became too great for these premises, and fine works were obtained at the present address, a view of which is given in our illustration. These works have been carefully laid out with special tools for manufacturing not only the switches and cut-outs, but all kinds of electrical accessories and instruments connected with electric lighting and engineering.

The works comprise some 12,000 square feet of floor space in three floors, with other premises for brassfounding, ironforging, battery making, carpentering, and lacquering behind the main building. The ground floor is occupied with the engine-room, lathes stores, and general offices. The machinery in use is mostly light lathes and drills, etc., and the power is obtained from one 4 and one 8 h.p. nominal Otto gas-engines, working to 24 h.p. One of these, it may be interesting to remark, was the gas engine originally put down at the Finsbury College. After his experience with steam-engines at other works, Mr. Cockburn elected for gas-engines in these, and is greatly pleased with the result, giving a strong testimonial to the Otto engines. Not only is there no worry in looking after the furnaces, but the actual cost of running, as shown in the monthly bills, is far less than with coal. The engines can be started at any moment, there is no banking up of fires, and the running of the engine requires no extra men. Extra power can also be thrown on at a moment's notice if required to test dynamos for customers. It is intended to shortly put down another gas-engine and a 500 light dynamo for completing the lighting of the works.



View of the Acme Electric Works, Kentish Town.

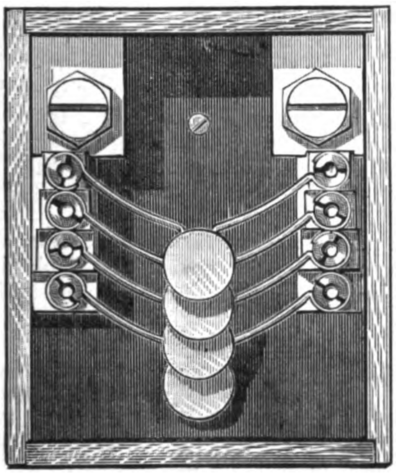
In the engine-room some large cone pulleys are being fitted up, so that dynamos can be tested at any desired speed. One of the features of these works, as will be seen further on, is that of electrical testing generally for clients; but besides this, it is intended that all dynamos and motors—whatever the make of machine—that are put in installations, as well as arc lamps, will be tested here before being sent away. A railway runs from back to front of the premises to facilitate loading and unloading from the waggons in the street.

STORES DEPARTMENT.

As the works are laying themselves out for supply of all kinds to the trade of electrical fittings, a considerable amount of space is taken up with stores in both raw and finished state. Casing of all kinds is stocked: wire and cable for installations; metal in plenty, rod, bar, and sheet—for screws, terminals, and parts of switches, etc., and steel and iron for magnets. In one large storeroom are large numbers of the various parts of switches and cut-outs, etc., stamped and partly finished, ready for making up in quantities. Battery pots and materials are stored in large numbers; bells and pushes, and Morse instruments, of which latter some dozens are in stock ready for dispatch.

Digitized by Google

A very large quantity of glassware, shades, globes, etc., are stored for use in electric light installations. Ayrton and Perry ammeters and voltmeters are another speciality which this company have right to manufacture, and large numbers of the new spring instruments are kept in stock. Besides this, special stocks of Cock-

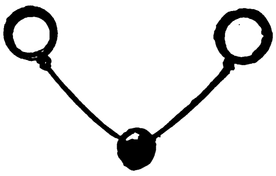


Step-by-Step Cut-Out.

burn's switches and Cockburn's cut-outs are kept: of the latter in all sizes, from ½ ampere to 200 ampere fuses, as many as 30,000 are kept in stock ready for immediate delivery.

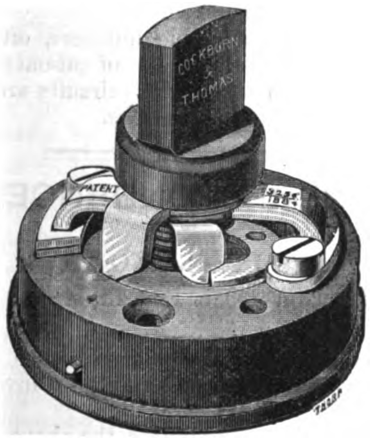
WORKS DEPARTMENT.

The works department is under the management of Mr. Sudworth, and is worked separately from that of the supply department, and a very complete system of ordering and checking out goods on order is adopted for quick delivery. The floors are arranged with long lines of light shafting, supplied by the Mechanical Appliances



Cockburn Fuse Wire.

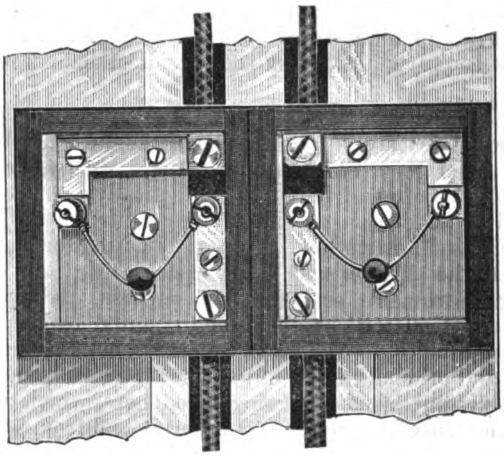
Co., Old-street, E.C., and a large number of light lathes and drills are fitted down the centre of each room, with vices and benches at the windows. The arrangement is very neat and convenient, with the newest and best type of tools for the purpose, carefully thought out and arranged by Mr. Cockburn, who seems to have quite a talent for mechanical organisation. The lathes and



Cockburn and Thomas Switch—Round Type.

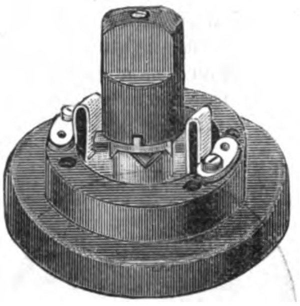
drills have all been specially designed and made for the requirements; the drills by Pfeil and Co., and the lathes by W. Cook, of Vauxhall-walk, all similar and interchangeable. A point worthy of note by users of shafting is the use of Bell's asbestoline, to which Mr. Cockburn gives high praise. Lubricators for the new lubricant were put in at the request of the Bell's Company, and have given most excellent results. The asbestoline is a kind of lard, very little is consumed, the shafting never runs hot, and no trouble at all is given, and no trace of oil, usually a great source of dirt and annoyance, is found from drippings on the flooring from the oilcups.

In this department we see cut-outs, switches, switch-



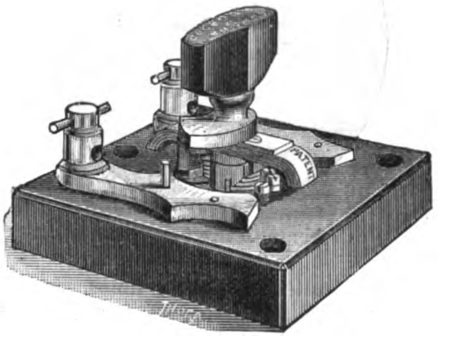
Double Pole Cut-Out.

boards in abundance in all stages of manufacture; wall-plugs in ebony and walnut; electric bells for the Admiralty; large numbers of telephones and telegraph apparatus. Here it may be mentioned that the Acme Works have a contract for making telephones and instruments for the New Telephone Company; as many as



Small Switch.

200 telephones a week have been supplied, and the company also make all their switchboards, and, in fact, most of their apparatus. Numbers of Ayrton and Perry instruments in various stages of completion occupy one section; they are the makers of the old form of these instruments, and also have the present exclusive right of manufacture of the new form of hot-wire instruments lately described by Profs. Ayrton and Perry. Terminals, caps, washers, screws, etc., are made in large quantities with special machinery, not only for use on the instruments made in the works, but also for the trade.



Cockburn and Thomas Switch—Square Type.

Behind the main building are two sets of outbuildings—one used as foundry and battery shop, and the other as carpenters' and lacquering departments. The foundry has lately been fitted up with smiths' fires and anvils, and with self-contained blast furnaces for brassfounding. The battery shed is used for making up Daniells and Leclanché cells. Ten carpenters are kept constantly at

Digitized by Google

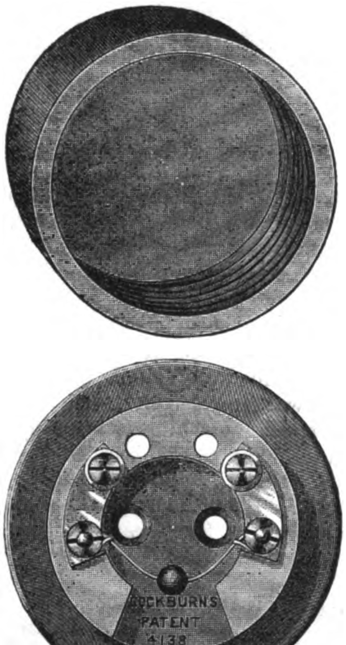
work in the carpenters' shop, principally making cases for instruments, and bases for switches and switchboards, etc. Coil winding for magnets and bells goes on here also, in which work girls are employed; as, also, in lacquering. One special department is arranged for the manufacture of the little "Cockburn fuses." A caretaker lives in the upper portion of these premises, and a staff of men is kept near at hand in case of sudden call for emergencies, or for installation work. A total of 130 men are now employed, including the outside staff.

Testing Department.

A special feature in these works in the future will be a testing laboratory, which is now being fitted up, designed by Profs. Ayrton and Perry, and practically carried out to their ideas under the superintendence of Mr. H. B. Bourne, of the Central Institution. This will be used for standardising all the Ayrton and Perry instruments, and recalibrating instruments sent for that purpose, and will also enable electrical tests of all kinds to be undertaken, under skilled assistance, for the trade, inventors, or experimenters. A new and original universal instrument—details of which are not yet published—is being fitted here, which will be able to measure from 0·1 to 600 amperes, and from 1 to 500 volts, in one instrument. Power will be arranged for tests of dynamos, etc., and a set of accumulators will supply current for testing small motors as well as lamps. Facilities for practically testing the fusing points of cut-outs of all types are also arranged.

Specialities.

The illustrations show the new form of the well-known Cockburn patent cut-out, mounted on china vase, with china cover. The little fuse of these cut-outs is shown separately, weighted with lead shot in the centre, to give a quick and clean break on slightest softening of the wire by excessive current. The fusing current in all cases is very very little over the maximum allowable current, and certainty of action is admirably secured.



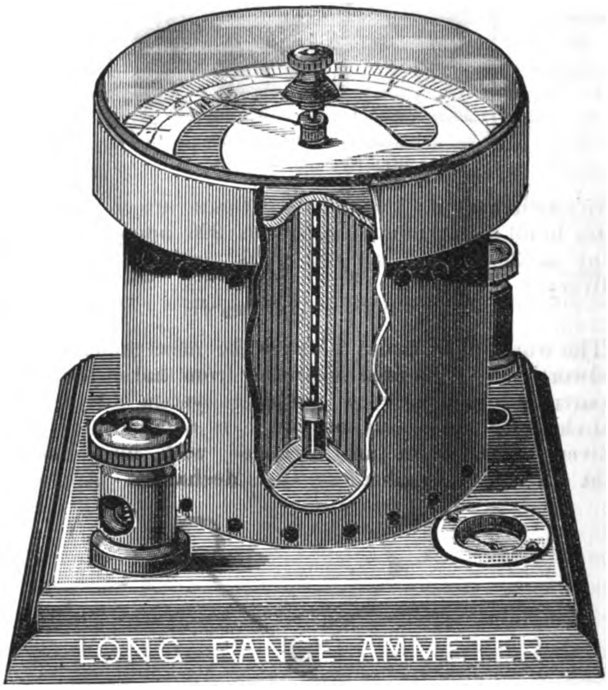
Cockburn Cut-Out on China.

The fuses are mounted on eyelet holes, easy to quickly fasten, and are put up in quantities for use in cardboard boxes, in sizes to go at from 1 to 200 amperes. The form used for double-pole cut-outs is also shown. Many thousands of these cut-outs are manufactured for use in installations all over the world. The General Post Office has some hundreds in use. The Royal Arsenal also has adopted them. The large size cut-outs for heavy currents are made as shown, with four successive steps of fuse wire, one behind the other, for ease of manipulation or of altering the safe carrying power.

Two forms of the Cockburn and Thomas quick-break switches are shown, which are made in very large quantities. These have already been described in the technical, and the action is well known. Suffice it to say that the connecting-piece is loose from the handle, which releases a spring, and breaks circuit very sharply and suddenly. They are made in slate, china, or serpentine, with either plain or ornamental covers, and are in great request for better class electric light installations. A newer type of small switch is also shown. In this the pull of the spring is downwards; the handle has a star-shaped projection fitting into the slot, and on turning the connection is quickly broken without possibility of the circuit being half on or off. It is a neat and simple little switch.

Instruments.

Electrical instruments of various kinds are made at these works—galvanometers, detectors, telegraph instruments, telephones, bells, etc. The principle speciality is of Ayrton



Ayrton and Perry Long Range Ammeter.

and Perry measuring instruments, of which the longe-range ammeter is one of the most in demand. New forms of these instruments are being perfected, and will shortly be brought on the market.

Double-pole Switches and Switchboards.

Switchboards and various arrangements of double-pole switches, with corresponding cut-outs arranged on the same base, are made in considerable numbers, often designed specially for installations; and sets of cut-outs, on slate or china bases, for distributing various circuits are also manufactured for use in large installations.

CORRESPONDENCE.

DOES INVENTING PAY?

To the Editor of the Electrical Engineer.

Sir,—There are few more fascinating occupations than inventing; and probably there is no branch of science or of engineering that is more prolific of inventions than electricity.

To electrical engineers, therefore, the above question will naturally present itself with greater interest than to almost any other body of men.

Everybody has heard of Graham Bell's lucky hit, of Mr. Swan's splendid *coup* on the advent of his lamp, and, more than all, of Edison's marvellous rise from a train boy to his present position. Tales, too, reach one's ears of this and that man who is drawing so many thousands per annum for some simple apparatus that we feel quite sure we could

Digitized by Google

have invented very much better—if it had only occurred to us. It was just our luck that it did not occur to us.

Sad to relate, however, it must be confessed that, as a rule, inventing does not pay. It is very much like gold-digging. We hear of the fortunate ones who make a lucky find, but we hear nothing of the hundreds and thousands who find nothing, or worse than nothing, who lose health, fortune, and the chance of rising in an honourable, if plodding, humdrum employment. To understand the apparent paradox that fortunes are made by inventors, that still greater fortunes are made through invention, and that humanity at large has its path smoothed for it by invention, yet that inventing does not pay, it is necessary to go into the question of cause and effect. It is necessary to remember that, unfortunately, a man has but one head, one pair of eyes, one stomach; and that nature will only allow of that one set of apparatus working for a certain number of hours per day. Further, that to invent anything, however apparently simple, requires usually the expenditure of a very great deal of time, of money, and of thought. Also, that after the invention is, to all appearance, complete, the rough test of actual work has to be applied; and this test often discovers sources of failure the inventor never dreamt of. This little thing which worked so beautifully at home utterly refuses to do so in public. That part of the apparatus upon which so much time and labour had been expended, is found to have been designed upon principles and to conform to conditions that are the exceptions and not the rule in practical every-day life; and all this demands more time, more money, more thought, and, moreover, take years from the inventor's span.

And even when all these difficulties are surmounted; when the apparatus not only works in private, but in public, too; when the inventor's trembling hands have been rewarded at last by success in full view of those cold eyes that only want to see whether the thing works or not, and who only then give a qualified approval—"It works all right so far; will it stand such and such a test?"—who know nothing of the inventor or his struggles, and probably care nothing; to whom that which the inventor considers a grand triumph is only to them fairly good—what then?

Supposing all these dread ordeals to be safely passed. Are the inventor's troubles over? Not a bit of it. They have only just commenced. He is like the proverbial young bear. The troubles he has gone through are as nothing to those he has yet to face. "What," says some sanguine inventor, "do you mean to tell me that when I have made my apparatus work in public—mind, in public, sir—that my troubles are to come?" Assuredly, my dear sir; if not, you will be as lucky as the proverbial man who is better off than if he were born rich. Anyone can lead a horse to the water, but no one can make him drink. It is not anyone who can invent, and those who can sell their inventions are fewer still.

Remember, if your invention is to succeed, it must be able to advantageously displace apparatus that is now doing the work; and, further, it must so advantageously displace it that the buyer or user of the apparatus is a gainer pecuniarily by his purchase. You may prove, if you like, that your apparatus is a better one, that it does its work at a smaller cost; but will the user gain if it is out of order half the time?

Take the telephone, for instance, which is a remarkably favourable example of an invention. A merchant keeps so many boys to run between his two or more places of business, carrying messages, parcels, etc. He is approached on the subject of having telephonic communication between them. He likes the idea immensely. He will be able to *hear* if his employés are at work, etc., etc., and it will cost him less than the sum he now pays his boys—if all works well. Besides, he will not be everlastingly annoyed every time those urchins get playing marbles, etc.

But supposing that for one day in the week, at uncertain intervals, he cannot rely on his telephone, where is his gain? His business must go on; therefore his boys are kept, and the telephone becomes an expensive luxury, and Mr. A is apt to give his experience to his friends as he comes to and goes from business: "I like the thing immensely if it would only work. Do you know, I can tell which of my clerks is speaking to me—when it is in order; but it gets out of order so often I can't depend on it."

And so his friends conclude to wait. "A tried it, and had to give it up; always out of order, I shall wait; daresay the atmosphere has something to do with it; doosid clever thing, but too delicate for me," etc. And that, readers, is what rules the market value of an invention. Suppose someone calls on you to ask you to buy a new—anything. A chair, if you like. Haven't you a hundred reasons why your old one is good enough, though, perhaps, the minute before you were anathematising it?

And it is this long period of probation, the creation of a *clientèle*, which makes inventing so hard and unprofitable, unless it be the inventing of new pleasures. It is the finding a buyer for your invention. While you are going about to this and that possible purchaser, that stomach of yours, and, possibly, other stomachs depending on you, require to be fed three or four times daily. Your back, and theirs, require clothing. Other events demanding expenditure transpire, and so it may happen, and often does, that when at last success does come, if it does, all-round success, work in private, work in public, sale of invention, etc., the whole of the proceeds have been eaten up beforehand.

Therefore, for a new year's gift the writer would give *Punch's* warning. To those about to invent, don't. If an idea comes in your way that can be worked out at little cost, benefiting you in your knowledge of the science, follow it for that benefit, but don't expect further reward.—Yours, etc.,

SYDNEY F. WALKER.

CENTRAL STATIONS WORKED BY UNDERGROUND MAINS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I read with much interest the letter from "Onlooker" in your last week's issue, but I regret that that gentleman has not carefully read the claim which is being put forward at the present moment by my company—which is that the station which the company has recently opened in Kensington is the first completed station in the metropolis designed for the accomplishment of electric lighting over a large area by means of underground mains.

At some future day this claim will only have a historical interest, but my directors would be sorry to put forward a claim which was incorrect, and in doing so they do not by any means ignore the work which is being done by the Kensington Court Electric Light Company; but from Mr. Erskine's recent letter in the *Times*, it is evident that the company do not claim to be working over an extended area.

It would be out of place to trespass upon your space by drawing attention to the various opinions which have been held from time to time as to the proper area for electric lighting, but it will be no doubt of interest to your readers to know that a high-tension system, such as that which has been installed by us in our Kensington station, is able to claim the power of coping with a large area, which a low-tension system, like that adopted by the Kensington Court Company, could not cope with.

Your correspondent's information in reference to the Zipernowski-Deri-Blathy system is most interesting; but as they have have not laid down a central station in the metropolis, the gentleman signing himself "Onlooker" must see that Signor Emilio Magatti's letter has no bearing whatever upon what he calls the repeated and positive assertions of the House-to-House Company that theirs is the first completed station in the metropolis for carrying out the work in the manner described.—Yours, etc.,

H. ST. JOHN WINKWORTH,
Secretary, House-to-House Electric Light Supply Company, Limited.

Bishopsgate-street, E.C., February 5.

Electric Organ.—An electric organ has been erected at Parkstone Church, near Bournemouth. The keys and pedals, which are at a considerable distance from the instrument, are controlled by electromagnets.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months.
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places	4s. 10d.	...	9s. 8d.	...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

SUPPLY COMPANIES AND THE BOARD OF TRADE.

We know that according to Shakspere "Divinity doth hedge a King," while according to our own experience civilised humanity is hedged round by legislative restrictions innumerable, so that perforce he must walk along a very "strait" road. In fact, the acme of civilisation seems to be found in the shibboleth—restriction. From our earliest childhood to the last moment of life the one great text to be learnt seems to be "A man must not." The ending may be "marry his grandmother," or "take a walk along this road." The early commercial pioneers in any industry have a hard time in learning what they "must not" and what they "may do" without incurring legal disabilities of an awkward character. Nobody knows what he may do till he tries, and then the most innocent action may be met by restrictions in every direction, while other work of a more sweeping character goes scot free. When an attempt is made to introduce a new industry like the electric light industry, where conduits radiate from a centre to points of actual use in every direction, the difficulties of overcoming vested interests are enormous. Rights here and rights there have to be acknowledged and provided for, and this, in addition to the overcoming what may be termed the conservative inertia, which necessarily exists in all civilised communities, as well as direct and interested opposition.

The Board of Trade in its circular to the vestries has determined one point which electric supply companies must not do. According, as we read the circular, no supply company can by leave of the vestry take up the roads to lay mains. The company must, in the first place, obtain statutory powers, and—well, does it follow that, having the statutory powers, the company can proceed in opposition to the local authority, or must its consent also be obtained? This question is necessary, because statutory powers *may* in exceptional cases be granted, in spite of the opposition of the local authority. It may, therefore, happen that a supply company will occasionally find itself in the position most aptly described as being between the "devil and the deep sea." It may have statutory powers, but not the consent of the local authority, just as it may have the consent of the local authority without having statutory powers, although in the latter case there should be no difficulty—except increased cost—in complying with all the requirements.

It will be better to give the full text of Mr. Calcraft's circular, which reads as follows:

"Board of Trade (Railway Department),
"London, S.W., January 29, 1889.

"Sir,—I am desired by the Board of Trade to state, for the information of the Vestry, that their attention has been called to the fact that certain streets in the parish of . . . . have been, and are being, broken up with a view to the laying of mains

for the supply of electricity by persons having no statutory powers under the Electric Lighting Acts 1882 and 1888.

"The Board of Trade have been advised that no member of the public (and a company not possessing statutory powers would be in the position of a member of the public) can, either with or without the 'assent of the local authorities, interfere with public highways in such a way as to cause obstruction to the public, even though such obstruction were limited to the time during which they were executing their work.'

"It is, in the opinion of the Board of Trade, very undesirable that mains for the supply of electricity should be laid down in any street being a public highway by persons possessing no Parliamentary powers.

"The applications for statutory powers now before the Board of Trade show that there is considerable competition in the metropolis for the privilege of supplying electricity, and the difficulty of dealing with these applications in the general interest of the public will be materially increased if individuals or companies have laid mains without statutory powers, and, consequently, without the obligations which the Legislature has imposed for the protection of the interests of the public.

"It must also be remembered that the financial interests of electric undertakings which occupy streets with their mains, and supply electricity to the public, without statutory powers are by no means secured in the same way, and to the same extent, as if they possessed those powers; since, in the first place, their works run the risk of being stopped by the direction of a court of a law, at the instance either of some public authority, or of anyone who may at any time, now or hereafter, feel himself aggrieved; and since, in the next place, they do not possess the remedies for enforcing against their customers their charges, which the Legislature has given to those who obtain statutory powers.

"The status of applicants to the Board of Trade, and through them to Parliament, should be such as to ensure perfect equality to all, and there is danger that this might not be the case if any persons, either being or about to be applicants for statutory powers, were in the actual occupation of streets.

"It has become, therefore, necessary to consider the action which may have to be taken in view of the facts above referred to, and I am desired to request the early observations of the Vestry upon the points mentioned."

We have no doubt this circular has been drafted principally for the reason indicated in the fourth paragraph—the excessive competition in various parts of the metropolis—and to the efforts of some of the companies to follow Josh Billings' advice as given in the second line of the well-known distich:

"Happy the man whose cause is just,
Twice happy he who gets his blow in fust."

There has been a race to be in possession, evidently with the idea that possession is nine-tenths of the law, and there would be far less likelihood of getting the cold shoulder than by taking the chance of obtaining statutory powers among half-a-dozen strong competitors. We are not quite sure but that our sympathies are somewhat in the direction of the last line, and the company that has risked ten thousand pounds on laying mains will probably succeed in getting statutory powers for that particular district against those who promise to do the work. At any rate, there can hardly be two opinions as to what is past—whatever may be held as regards the future. There has been a race—let those who are in remain in, and those who are out seek new fields of operation.

With regard to the fifth paragraph of Mr. Calcraft's circular, depend upon it most of the directorates engaged in electric lighting operations in London at the present day are about as wideawake as you can make them. They will be able to take pretty good care of their own interests without any grandmotherly interference of the Board of Trade. As for the ability to buy and sell electric energy, and generally to get accounts in from their customers, that may be left to raise a smile upon the face of the unsophisticated aborigine—"Golly, massa, me hab light for noting." Worthy householders will think twice before they put any trust in circular phrases, and if they agree to buy so much electric energy will expect to pay for it—or take the consequences. As regards the penultimate paragraph, the position is described by reference once more to Josh Billings. The hurry of the man in possession has been taken with the one great object continually before him—to be in a position of inequality with his competitors. Whether his position is better or worse—*quien sabe?*

MOLECULAR PHYSICS AND THE NATURE OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I have before me a MS. paper, written a few years ago, on "Molecular Physics in High Vacuo," with a sequel essay on "The Mean Free Path of Atoms," in connection with the celebrated Crookes' experiments.

The subject is now renewed by an American electrician, Dr. P. H. Vander Weyde (*Electrical Engineer*, January 4th, 1889.)

His style of writing is by no means clear, and his statement of facts is very bald after a pretentious historical treatment of the subject. His version of the facts may be summarised thus:

(1) That dry air is a bad conductor of electricity, or what he calls a "good non-conductor." With ordinary power, it is an insulator; but with high power, a spark of 6in. may pass through it.

(2) That in proportion as air becomes attenuated, it becomes more and more conducting, up to the limit of ordinary air-pump capacity, when the aurora-like Geissler tubes are so familiar.

(3) That when the exhaustion exceeds one million-fold, air becomes a perfect non-conductor, evincing new properties, justifying Mr. Crookes' claim for a new fourth condition of matter, "as far removed from the gaseous state as gas differs from liquid."

What chiefly concerns me herein is the statement, which is the chief object of his paper, that Mr. Crookes has provided the true explanation of the new facts.

Of course, I object to his introductory estimate of both astronomy and chemistry, the former as dealing with the

Digitized by Google

infinitely great, involving motions which are *indestructible*, "a perfect *perpetuum mobiles*." The latter with atoms immensely distant in proportion to their size, endowed with a miraculous "everlasting motion, as indestructible as is the motion of the planetary bodies."

We hold that both these assumptions are unwarrantable, if not wantonly absurd. I would rather moot that the facts or modern conceptions of astronomy, in harmony with all other facts, evince a wonderfully vast picture of life and death; that the intervals of planetary life may be vast in common with all the other features of a wonderful cosmos, but that these motions spring *from adequate causes*, and that all pass through the stages of infancy, maturity, and death.

As to the size of atoms or their distance apart, I have endeavoured to show that the whole thing is a mistake—that no experiment or calculation has ever been made for either, and the estimates, which are enormously discrepant, can only refer to the distance apart from centre to centre. When able men like Sir Wm. Thomson and others talk of the size of atoms or of their distance apart, they talk loosely or with inexactness.

I am tempted to quote the above paper at page 5. Mr. Fowler Preston says, according to the mathematical results obtained by Clerk Maxwell and others, "the molecules have a mean distance apart of $\frac{1}{7000000}$th of an inch, or ·000000143in.; Mr. Crookes estimates 21 millions to the inch; Clerk Maxwell, 50 millions; and Sir W. Thomson has hitherto estimated 500 millions to the inch, but now extends the range to 2,500 millions." From seven to 2,500 is a tolerably wide range, and if this is the kind of ground Mr. Vander Weyde likes to explore I envy not his taste. As to the mean free path of these atoms, extending from four millionths of an inch to 60 million miles, and their miraculous kinetic motions, I have said enough on these points, and pass them by here, except that the following is quite new to me: "The number of atoms in one cubic inch of the common air we breathe is represented by a series of more than 20 figures (rather vague!), and they are in constant continual motion to the number of 10 millions per second (yet more vague—what does he mean?); while the velocity is so great, that if moving in a straight line they would pass through a space of 11,000ft. per second."

Clerk Maxwell has shown that hydrogen must bombard its fellow atoms or the sides of a vessel with a mean velocity of 6,097ft. per second, "beyond our best artillery practice," in order to account for the observed pressure; as if that phenomenon were not simpler and better explained without a huge scaffolding of mathematical analysis based on a miracle of assumption.

The distinction between solids and liquids is curious: "When the amplitude (in solid bodies) becomes so great that the atoms turn over, and commence to rotate around their centres, the body reaches its melting point, and becomes a liquid. As the velocity of rotation becomes greater the liquid becomes hotter, until a new set of phenomena takes place. The atoms are projected into space, and in place of rotating they are propelled and repel one another, and as millions upon millions exist in the small space of one cubic inch collisions take place by billions, and we have the gaseous condition. If this be not wanton trifling, what is it?" How does he know that atoms vibrate so and so in solids; that in liquids this vibration is changed to rotation, while further heat changes this rotation back again to vibration on a larger scale, etc.? But perhaps the greatest absurdity of all is the new fourth condition, or "radiant matter."

Besides a full refutation of this in the paper referred to, I have since jotted down the following note: "A so-called radiator mill is shown, driven by the supposed mechanical stream of *radiant matter*. But the electromotor power from the induction coil is removed, and the platinum wire which had acted as the negative pole is now heated, and the dark heat *vibrations*, impinging on the vanes, set up the rotation precisely as before." Surely this tells very strongly against the "radiant matter" theory. Light, heat, and sound *vibrations* are dynamic affections, and either will set a mill rotating. The vanes of a windmill radiate, but we don't call such mill a radiator. Mr. Crookes tells us what are the distinguishing properties of "radiant matter."

(1) "Radiant matter, when interrupted by solid matter, casts a shadow." This is precisely what takes place with the radiant forces of light, heat, and sound.

(2) "It exerts mechanical action where it strikes." This is precisely what radiant force does in the window-breaking intensity of loud concussions.

(3) "It is deflected by a magnet." This is precisely what takes place with the radiant or linear lines of polar force.

(4) "It produces heat when its motion is arrested." This is precisely what takes place when the radiant affections of light and heat are arrested.

Mr. Vander Weyde says: "Heat and light will both pass through a vacuum perfect enough to obstruct absolutely the passage of electricity." But here, again, and throughout what follows, we have the interminable confusion subsisting between matter and force, and all depends upon the meaning he attaches to the vague term "electricity." It is commonly held that electricity is convertible into heat and light! But that is only true of the dynamic *force* of electricity, and in principle it is equally true of the hydraulic *force* of water, but we do not say that water is so convertible, and we know that the ions of electrolysis are material and inconvertible, and also that the electric current is absolutely inconvertible, seeing that the quantity of electricity going into a lamp is the exact measure of the current passing out.

There is no more consumption or conversion of this electricity in electric lighting than there is water consumed or converted in the production of hydraulic effects of any character or magnitude whatever. Anyone wishing to further entertain this subject may peruse the above paper on application to—Yours, etc.,

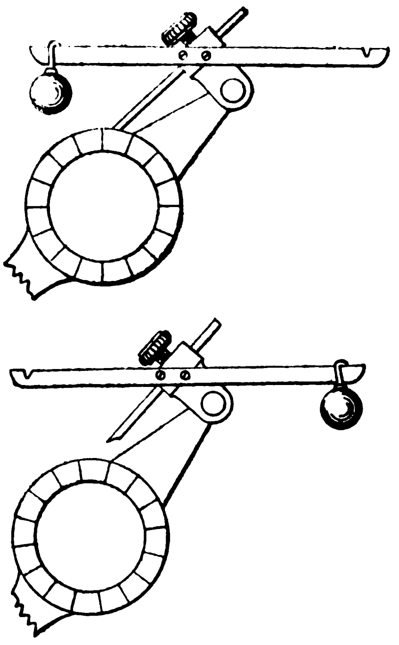
SAM. E. PHILLIPS, F.C.S.

Wokingham-road, Reading, Berks.

BRUSH-HOLDER.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I enclose a sketch of a new form of brush-holder which ought to be used on every dynamo intended for



practical use. I have found from experience that no form of holder in which a spring is used is satisfactory for two reasons—firstly, because the spring is sure to become soft and useless through the heat to which it is raised; and secondly, because it is generally next to impossible to get the man in charge of the machine to keep the right amount of tension on the spring. If the machine sparks, he will, in nine cases out of ten, increase the tension, with the result that the commutator will be worn out in a few months. I have known this happen in a great number of cases, and have often seen the brush-holders (even in machines by the best makers) tied over with string to increase the pressure of the brushes on the commutator.

In the case of the brush-holder shown in the sketch the

Digitized by Google

balls can be easily adjusted to give the exact amount of pressure required to give a good contact with the least possible wear and tear, and after leaving the factory there is no chance of damaging the machine by increasing the pressure. This may seem a small point, but it is just the neglect of these small practical details in the construction of electrical apparatus which so hinders the progress of electric lighting, especially in the case of isolated plants, where a collection of spare parts cannot be always kept on hand.

I do not know of a dynamo in the market (with the exception of one of Parson's high-speed machines) which is fitted with any form of gravity brush-holder. In every case some more or less complicated piece of apparatus is used, controlled by one or more springs, which costs considerably more to make, is not in any way more efficient, and is constantly getting out of order.—Yours, etc.,

Duart House, Lee, Feb. 5. W. M. HITCHCOCK.

INFORMATION WANTED.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—In your issue of Jan. 4th, this year, in reviewing the different firms, you stated that Messrs. Immisch and Co. had made for the Wharncliffe Silkstone Colliery a self-contained locomotive (which I presume is worked by secondary batteries). Could you kindly give me a few more particulars? I should like to know how much the engine weighs, and how much it can draw; whether the wheels are single or coupled, and what size, and what kind of gearing is used. If you think of publishing a sketch, would you kindly let me know? I am afraid that I have asked more questions than you like to answer, and would take up too much space. Any information will be thankfully received. Yours, etc., A. M. BUSHELL.

36, Queen's-road, Bayswater.

EXTRAORDINARY PHENOMENON OF LIGHTNING.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—This (Saturday) evening, February 2, at 7.35 p.m., wind N.W., sky cloudy, thermometer 38deg. F., a tremendous fireball, about two metres in diameter, accompanied by a fearful explosion of only two seconds' duration, descended from the sky, which seemed to split into four quarters upwards, showing a *bluish* fiery light. The explosion was unlike thunder, and more like a fearful detonation of explosives, which was followed by a snowfall of only two minutes' duration, leaving 1½in. of snow on the ground, the atmosphere being after splendidly pure. It would be interesting to know if this phenomenon has been observed in this and other quarters, and under what condition.—Yours, etc., ERNST FAHRIG.

Stamford Hill, London, N., Feb. 2, 1889.

ON THE RELATIVE PROPORTIONS OF RING ARMATURES.

BY R. S. DOBBIE.

Being a great admirer of the ring armature, the value of which the French Senate and Chamber worthily acknowledged by awarding the Volta prize to M. Gramme, I think that a few remarks on the proportion of the radial depth to the axial length would be interesting to many readers of this journal. In the design of a dynamo the mass of the armature is the first thing to be taken into consideration. A given weight of iron can be arranged in many ways, each of which under similar conditions of peripheral speed can give equally good results. For instance, the performance of an armature in which the radial depth of core is half the radius, and placed in a system of magnets adapted for it, can be equalled by an armature in which the radial depth is, say one-tenth the radius of ring, the fields in this case also being adapted to it, and the conditions of speed, mass, and total strength of magnets being the same in both. And not only does this hold good here, but also with the drum armature, which I look upon more as a modified Gramme ring, in which the radial depth of core nearly equals the radius of the armature, than a modified Siemens shuttle armature. A drum armature with equal speed and field can be strictly compared with one of the ring type of equal mass.

The core of any armature has three important functions to perform. First, to use a conventional term, it acts as a path for the lines of force from the field-magnet; second, it has magnetic lines of force induced in it by the action of its own coils; and third, it acts as a support to these coils. Each of these functions involves the following conditions respectively: First, the path for the inducing magnetism from the fields, and hence the surface presented to the pole pieces *must be large*; second, the lines of force generated in the armature *must be few*; and third, the shape or proportion of the ring influences the *length of a convolution* compared to its mass. Since the circle is the shortest line which can enclose a given area, theoretically considered the circle should be the section of a Gramme ring; but the difficulty of constructing this shape has led to the almost universal employment of rectangular sections, with the corners rounded for convenience of insulation and winding. Let us now consider the effect of lengthening the rect angular section in proportion to the radial depth of the ring. We have here six rings, Figs. 1 to 6, in which the sectional area, a (= 16 square inches), and the mean radius, $m\,d$ (= 12in.), are equal in all the rings. It will be seen that the length of one convolution, l, creeps up in a startling manner, and it is obvious that if this were the only consideration, the square section (barring the circle as impractical) should be selected.

But there are other points before us, such as the clearance between the core and the pole-pieces, which I will call the inductive space, and which must be small in a radial direction and large in area. For the sake of illustration and comparison, we will suppose that 50 per cent. of the angular breadth of the ring is covered respectively by pole-pieces, first on the outside surface only, as usually practised, which area is designated by p_1 in the tables accompanying the figures; second, by pole-pieces on the outside and the two sides, as in Mordey's dynamo, and designated by p_3; and third, by pole-pieces on the outside and inside, as in the Fein and Sperry dynamo, and designated by p_2. It will be noticed that at the stage of elongation shown in Fig. 4, the value of p_3 ceases to be larger than p_2. It will thus be seen that the longer we make the ring the greater is the surface presented, but so also is the length of one convolution, l.

As the ring, as just stated, serves as a path for the magnetic lines of force, it is evident that the area of the field should be in proportion to the area of the armature, and the area of the pole-pieces should also be proportional to a given area of field-magnet. This latter point is one that I have never yet seen any hard and fast rules laid down for. Now, theoretically, it is evident that the sectional area of a field-magnet should be equal to twice the area of the ring (remembering that in every ring the lines of force from the field-magnets have two available paths). For example, those shown in the figures being 16 square inches, the field-magnet should be 32 square inches; that is, supposing that things could be so arranged that all the lines of force from the field-magnets could be utilised in the armature, and, of course, assuming that the saturation was the same in both. In practice, the magnets are generally made of metal inferior to that of the armature; but as the latter contains quite a percentage of inert matter in order to carry out the necessary lamination, and as constructors are more and more awakening to the fact that wrought-iron magnets are cheapest in the end, the balance becomes more equal; so that in the end we can, in practice, allow only for a waste of lines of force, and if, indeed, it is worth while, a little difference in favour of the superior metal that armatures are usually made of.

From my own observation I have found that the area of the armature, multiplied by two, is ample, if the field-magnets are of wrought iron, and the length of the inductive space is small (not exceeding ⅜in. in the above example). The fields should be nearly, if not quite, saturated in order to ensure steadiness; but the magnetism induced in the armature should be considerably short of

Digitized by Google

saturation, as an armature will heat even if laminated, should it be magnetised to saturation, thus still further reducing the necessity of difference between the respective areas. And here let me make a note about lamination. It is often found that constructors use extremely thin sheets separated by the very thinnest paper, which by no means *thoroughly insulates* one plate from its neighbours. I believe that it is a useless refinement to have the disc forming the armature thinner than one-sixteenth of an inch. If these are really substantially insulated, so that after being turned true the plates have a resistance of over 10,000 ohms between each other, or, more practically speaking, will not allow an ordinary magneto bell to ring through, it can be relied upon that *insulated lamination* has been properly carried out.

Taking, therefore, for the sake of argument, the ground that the area of a field-magnet is twice that of the ring, let us return to the question, How large should the surface of the pole-pieces be? Referring to the figures, and assuming that 50 per cent. of the angular breadth is enclosed by pole-pieces, we then have for the different shapes, ignoring the circle as impractical, the values shown in the tables accompanying each diagram.

as the many examples we can all call to mind show that after a certain limit is reached it is useless, and even detrimental, to go beyond; but the angular breadth can be reduced with advantage, and *more poles may thus be presented to the ring.*

One more point is brought out by comparing the figures. The difference between the internal and external diameter of the square-section ring, Fig. 2, is far greater than in Fig. 5, and if both were wound with, say, one layer of wire, inside and out, with no overlapping, the difference in number of turns would be *20 per cent. in favour of the long ring* (Fig. 5). It will thus be seen that while the length of a coil becomes greater as the ring increases in length, so does the internal diameter of the ring, thus allowing a greater number of turns, or a thicker wire, to be used.

Referring again to Fig. 2 and Fig. 5, we have 16in. and 20in., respectively, as the length of one turn—that is, a difference of 20 per cent. in favour of the square section, Fig. 2; and as the E.M.F. is proportional to the number of coils, and the current is proportional to the resistance, we have things balanced, and only have to choose between the difference of constructional advantages in them.

D, External Diameter of Ring; d, Internal Diameter of Ring; $m\,d$, Mean Diameter of Ring (equal in all the figures); a, Area of Cross-section (equal in all the figures); l, Length of One Turn of Wire; p_1, Total Area of Pole Pieces, embracing 50 per cent. of outer periphery only; p_2, Total Area of Pole Pieces, embracing 50 per cent of outer and inner periphery; p_3, Total Area of Pole Pieces, embracing 50 per cent. of outer periphery and the two sides.

So many machines have the surface and also angular breadth of the pole-pieces so enormous, compared with the section of the field-magnets, as to be simply ridiculous. On such machines I need hardly add that the "beautiful spark playing around the brushes" that is so much admired by country cousins is ever present. There is no doubt that the present tendency is in the direction of narrower pole-pieces. I do not remember seeing a continuous current machine in which the area of pole-pieces was less than 1·5 that of the field-magnets, and I have yet to hear of any machine being condemned on account of having the area of the pole-pieces too small. I know from practical experience that about 60 square inches of pole-piece is ample for a magnet about 6in. in diameter—*i.e.*, 28·2 square inches—and four such magnets and pole-pieces could be presented to the square section ring, the pole-pieces embracing the outer periphery and the two sides (p_3).

I think that modern practice in alternating current dynamos where the area of the pole-piece frequently equals the area of the field-magnet, might be at least considered in the construction of continuous current machines, as both are fundamentally the same in principle. The resistance of the inductive or air space is overrated by constructors,

In conclusion, it will be seen that the various forms have their own peculiar advantages. The square section has the advantage that the length of one turn is a minimum for the area of the mass enclosed. If the pole-piece embraces the outer periphery and the two sides with 50 per cent. angular breadth, the area offered is ample. In rectangular sections the area of pole-pieces increases faster than the length of one turn. The winding is more symmetrical and lamination is more easily carried out; but if the length is increased beyond a certain limit the length of a turn becomes objectionable.

These questions will afford ample exercise for those inclined to grapple with them. So many minutiæ are involved, that a careful consideration of the conditions to be fulfilled is very necessary to success, and opinions as to the advantages of the various forms can by no means be given off-hand.

The subjects touched upon in this paper suggest many others, such as the number of poles, length of inductive space, and its relation to area of pole-piece and area of field-magnet, together with the ratio of radial depth of core to the mean radius of ring. These are subjects that give abundant material for further study.—*The Electrical World* (New York).

ELECTRIC METERS FOR CENTRAL STATIONS.

The following discussion took place upon the reading of Prof. Forbes' paper on the above subject (given in full in our last and previous issues) at the Society of Arts:

Mr. R. E. Crompton said he had had some practical experience with the Aron meter, but it had been principally through a third party—Mr. Miller, who could have spoken with much more authority as to its performance. They had at first enormous trouble with it, but were eventually successful, and it was through Mr. Miller that many of the improvements had been made. They commenced with another form of meter, which was not satisfactory, and which was now superseded by the Aron meter. In its original form the clock was started by a detent when the current was turned on, but that gave endless trouble, as the clock did not always start, and consequently they lost, not only a record of the rate between the visits of the attendant, but actually lost all record, as the meter registered back, which was a very serious affair. Mr. Miller made some suggestions which resulted in the simple clock which was now employed, and ran for 30 days, and since then many of the difficulties had been removed. He had recently spent some time in Berlin, and found that they were thoroughly satisfied with that meter, but he should say that it only registered the current supplied to incandescent lamps, whereas the success of the Berlin station depended on arc lamps, which formed about three-fifths of the whole, and they were charged mostly by contract. At Kensington they had never sold current otherwise than by meter, in which he believed they stood alone. At Liverpool, however, there was a central station which worked largely by meter, and by one which had not been mentioned—viz., the Chamberlain and Hookham, which, he was told, had been working there for some weeks, and proved as accurate as the Aron, and was in some points superior, though he did not know the particulars. He could endorse what had been said about the use of the Edison meter in America. He believed no meter had been more aspersed, but at the same time it had done infinitely more real work than any other, and it had been very unwisely neglected in this country. At the time Mr. Ferranti was bringing out his meter, Mr. Kapp and himself were experimenting on exactly similar lines, but Mr. Ferranti was a few days earlier in applying for his patent. With regard to lamps, if Prof. Forbes had had practical experience in lighting private houses, he thought he would advocate 8 c.p. lamps, because we had to compete with gas and keep down the annual bill. The greater part of the expense of lighting was incurred for passages, staircases, and so on, and for this purpose a unit a little over eight candles answered extremely well. Everyone who saw the so-called 16 candle lamps worked at the volts at which they were sent out by the Edison-Swan Company, admitted there was a great waste of light when used in such situations. These lamps originally yielded 18 candles, or more, but since the improvement in the manufacture of the lamps, they had been able to work them slightly in excess of what they were marked. Those marked eight candles and 97 volts could be worked at 102, and yielded about 11 candles when new, and when quite old the original eight. Customers who could buy the larger lamps if they liked preferred the smaller ones, and more than three-fourths of those in use were the smaller unit. This was not so in shops, clubs, or hotels, where larger lamps were more satisfactory; but to make the electric light spread rapidly, and not frighten the people by the cost, the smaller lamps should be encouraged. He greatly admired the magnificence of the Berlin central station, but it was very costly, and he thought the same result could be obtained in England for very much less money.

Prof. Ayrton, F.R.S., after paying a tribute to the modesty displayed in the paper, which he would endeavour to emulate, said he should like to break a lance with Prof. Forbes on the old dispute as to whether electricity should be charged by quantity or by energy. It seemed to him that people were somewhat influenced by the meters they had to supply, and naturally liked people to pay for a thing the meter would measure rather than that the meter should measure the thing they ought to pay for. No doubt, if it were possible to maintain a constant potential difference between the supply mains, the total quantity supplied in a given time was all that need be considered, but this constant difference of potential was not maintained. Prof. Forbes admitted there was a 2½ per cent. variation; but that amount of variation in the volts meant a very great difference in the amount of light, which was really what the customer thought about. He did not care about volts, watts, or anything else; he bought light, and wanted a meter to measure what he was paying for. A variation of 2½ per cent. in volts—and it was more in practice—meant a considerable drop in the light, which was about proportional to the cube of the volts, minus a constant, as shown by the experiments made by Prof. Perry and himself on several types of incandescent lamps some years ago. The other day he was in St. James's Hall, during an afternoon performance, when the light went down so much that the gas had to be turned on full. Supposing you were paying by current, you would pay not much less than if the right voltage were maintained between the terminals, and if a few more lamps were turned on the total current would be the same, but the light obtained would be nothing near the same, so that during that half-hour the customer would be paying the full gas bill, and the full electric light bill as well. In fact, so far from employing a meter which took no notice of any variation in the volts, as was advocated by Prof. Forbes, he was not sure but that the meter ought to take into account some higher power than the first of the volts, so that it would measure, perhaps, the integral of the product of the current into the square of the volts, seeing that the light fell so rapidly with the fall in the volts; but whether this was done or not, they certainly ought not, he thought, to be satisfied to neglect variations of even the first power of the volts on the indications of the meter. There was one point about the simplicity of testing which Prof. Forbes had not referred to, which existed in retarded clock meters, but in no others. During the time you were not using the electricity you could check the accuracy of such a meter, because the clock, which was simply retarded when the current was supplied, was not retarded at all when there was no current passing, and you could therefore compare the going of the meter during the day with any respectable watch, and with which it ought to keep time. No one of the other meters could be tested in that way. A way Prof. Perry and himself suggested some years ago of getting over the possibility of cheating in an ergmeter for measuring the product of the current into the volts, had a pendulum wound with wire, the wire round the pendulum being a shunt to the main circuit. By putting a magnet near the clock the consumer might prevent it being retarded so much, but it was proposed to occasionally reverse the current in the whole system, which could easily be arranged, and the result would be that anyone who tried to cheat by the use of a magnet would be as likely to increase his bill as to lower it. He agreed in the objection which had been raised to contacts in meters, but there was one meter, patented some years ago by his colleague and himself, which was not open to the same objection, though it had two contacts. It was a motor, the field-magnets of which were wound with thick wire, and there was a continuous circuit through them—no make or break at all. The rotating armature was wound with very fine wire of high resistance, and there were two brushes to lead the shunt current through the armature, and any changes in the resistance of the contact of these brushes made very little difference in the total resistance of the shunt circuit. There were no brushes in the direct circuit, and any slight amount of dirt which in time accumulated under the brushes in the shunt circuit introduced very little error. He ought to mention in passing that the ergmeter had no defect, in that it measured what the customer ought to pay for. If the supplier could keep a constant difference of potential between the terminals, then the ergmeter became a coulomb meter, but if the supply were variable the ergmeter checked the supplier if he did what he ought not to. He thought Prof. Forbes must be in error in speaking of fluid friction being proportional to the square of the velocity; with small velocities the retardation was not proportional to the square but to the first power of the velocity; with a velocity, such as existed in the beautiful instruments on the table, the vanes were not moving much faster than the needle in a ballistic galvanometer, and the damping correction of that instrument was, as was well known, on the principle that the retardation did not vary with the square of the velocity. Indeed, their own motor ergmeter, in which fluid friction was used, and which was patented in 1882, was based on the principle that the friction was proportional to the first power of the velocity. There they wanted to measure the time integral of the product of the current passing through the field-magnet, and the current passing through the armature, which integral was directly proportional to the energy. The force-causing motion was proportional to the product of the two currents, and if it were assumed that for slow velocities fluid friction was proportional to the velocity, the distance travelled through by the armature would be proportional to the watt seconds, or, in other words, to the total energy supplied. If the retardation were proportional to the square of the velocity, the meter would not have worked satisfactorily. While on the subject of fluid friction, he would allude to one defect with all these motor meters which had prevented them improving and introducing their own motor ergmeter. You wanted simpler fluid friction, not solid friction. You must not have the friction of mechanism, and therefore it was necessary to reduce the dials and recording mechanism to such very minute dimensions, and to make them so delicate, that great difficulty was introduced. That was the great difficulty with the Ferranti meter; if he had no recording mechanism his meter would have been perfect; but the friction introduced by the dial mechanism was a great difficulty, and he understood that though Mr. Ferranti had many thousand lamps at work where the current was measured by these meters, he was not yet satisfied with them, and was sending to America for machinery to make more delicate dial mechanism. The retarded clockmeter had no such defect, as the mechanism was not driven by the current. In one sense it was a defect to have to introduce another motive power, but by so doing you got over the difficulty he had mentioned. The friction of the mechanism introduced no more inaccuracy than was to be found in a good chronometer. With a motor meter it was absolutely necessary to reduce the dial mechanism to the smallest possible dimensions. His colleague and himself owed a debt of gratitude to Dr. Aron for the way in which he had carried out the principle they had put forward, and, as his agent had wisely commercially acknowledged their claims to priority, there was perfect accord. He was a little surprised to hear of the success of the Lowrie-Hall meter, which was based on the assumption that the alternate current, when passing through a voltameter or an electrolytic cell, produced no decomposition; but this had been found from the experiments made by his students, an extremely difficult condition to arrive at. It meant that if you sent an alternate current through a voltameter no gas would be produced, but, in fact, you could easily get a considerable amount produced, and you could get copper deposited with a current making many thousand alternations per minute. He was much surprised, and at the same time much pleased, to hear that this difficulty had been successfully surmounted. At the end of the paper Prof. Forbes had briefly described a meter which gave its indications by means of the evaporation of alcohol. A meter on the same principle was made at the beginning of last year by Mrs. Ayrton, mainly by her own experiments at home, though tests upon it had been subsequently made by her at the Central Institution. In that case, water was evaporated by the passage of the current; the water fell through a tube, and, according to her design, worked a recording mechanism, and was finally carried back to the reservoir to be re-evaporated. He had nothing to do with the invention himself,

Digitized by Google

and had, in fact, rather discouraged it, in consequence of the difficulties of such an investigation. He, therefore, now penitently desired to place her meter on record.

Messrs. Shoolbred, Smartt, and **H. Swan** also joined in the discussion.

Prof. Forbes, in reply, said he was very sorry Mr. Miller had not been present to give his practical experience, but he understood that at Berlin the single clock-meter was found more successful of the two types of Aron meter, and he was surprised to hear Mr. Crompton intimate that was not so at Kensington.* He was very sorry there had been any meter which had been successfully employed in central stations which he had not described. He was aware that Messrs. Chamberlain and Hookham had devised one, but did not know it had been in practical work, and he should make it a point to learn more about it. Since Prof. Ayrton had expressed a desire to break a lance with him on certain points, he should be quite willing to discuss the point in a few sentences. Prof. Ayrton tried to reduce his proposition to an absurdity; and he would endeavour to do the same with what Prof. Ayrton had said. It was intimated that those who made meters did not make them to satisfy the wants of the customer, but tried to make the wants of the customer meet the performance of the meter. The customer wanted to measure the quantity of light, which was proportional to the cube of the volts, and there was no doubt about it, according to Prof. Ayrton, the erg was the proper thing to measure, since this is what his meter measures—whilst he (Prof. Forbes) said the coulomb was the thing to measure—the total quantity of current passing through. He said no. When the lamps were burning down very low it was a great shame the customer should be charged almost as much as when they were burning brightly. Now, supposing he were supplied by meter and charged by ergs by the volts multiplied by amperes. Those who supplied the current would want to send a greater pressure through the lamps than the customer wanted, and so break them down, and the customer then would not only be injured by having his lamp destroyed, but insulted by being asked to pay more in his meter account for this. He thanked Prof. Ayrton for his information about another inventor who had been working on the same line as himself; a great many had tried evaporation, but he had not seen one which made the results proportional to the current going through the meter. With regard to the cost of meters he had very little information. In America the idea was that they ought to cost about £1 to manufacture, and sell at about double that price, but he did not think they would come down to that in this country. They would probably sell for from £4 or £5 up to £18 to £20.

The **Chairman**, in proposing a vote of thanks to Prof. Forbes, said it was quite true that he felt it extremely depressing to walk through the dull and dismal streets of London after coming from New York, which was brilliantly lighted by electricity; but on hearing such papers as this, he felt that there was a possibility of that depression being removed. He himself lived in an atmosphere of electricity, his own house being lit by it, and whenever he went to see his friends he could only pity them for living under the depressing influence of gas; and he hoped the day was not far distant when others would be as comfortable as himself. He believed we were on the eve of a boom in electricity. Only yesterday the Commissioners of Sewers of the City of London decided on issuing a specification and inviting tenders for lighting the City, and it was to be hoped that, before the end of the year, Fleet-street, Ludgate-hill, and Cheapside would even surpass the famous Unter den Linden. With regard to 16-c.p. or 8-c.p. lamps, he agreed with Mr. Crompton that when Prof. Forbes had had more practical experience of the fitting up of private houses, he would come to the same conclusion as Mr. Crompton and others, that the proper candle-power to use in houses was 8 or 10. In a large hall it would be absurd to use such lamps, but there really ought to be a new system introduced, as Mr. Shoolbred had said, of speaking of lamps not by candle-power, but of so many watts. The standard lamp in his practice was one of 50 watts. If people in the colonies or abroad sent home indents for an electric installation for so many thousand lamps no one would know what they wanted; but if they sent for so many lamps of so many watts they would know exactly what to send, the proper dynamo to give the current, and the batteries required to maintain it. Throughout the Post Office they commenced with 16 candle lamps, but found that 10 candle gave all the light required. The real question was not so much the power of the lamp as the proper distribution of the light. When you had decided on the amount of light required to read or write, or to do any particular work, it was easy to calculate whether the lamp should consume 30, 50, or 100 watts, because that simply depended on the position in which it was placed.

The vote of thanks was carried unanimously, and the meeting was adjourned.

Mr. J. W. Swan writes to the *Society of Arts Journal* as follows:

"Prof. Forbes has given us an admirable *résumé* of the present state of electric current meters, or at least such of them as have come into practical use. If he had extended his view so far as to embrace experimental meters, it would have been necessary for him to have given—not a lecture, but a course of lectures. The number of meters to be described would have been increased tenfold. Of this number, some that I have made, would, perhaps, have been thought worthy to come into the record. His lecture occurs at an opportune moment, when large projects are afoot for the distribution of electric current from central stations, and when, therefore, electric meters are an imperative necessity.

"Nothing more strikingly illustrates the rapid progress made during the last seven years in the use of electricity, especially in connection with lighting, than the fact that at the beginning of this period there was no such thing as an electric meter, and now there are thousands of electric meters in actual use.

"I remember very well when the details of the Electric Lighting Act of 1881 were under discussion amongst experts, the question whether electric current could be charged for by meter was asked by the Board of Trade, and it had then to be admitted that there was no instrument known that would measure electricity as a gasmeter measures gas. I ventured to express the opinion that although it could not be denied that that was the case, yet the principles upon which meters could be constructed were well known (the principle of electrolysis, as seen in the Daniell's battery and the voltameter, was the best known and most obviously applicable at the moment), and that considering how invariably under such circumstances supply followed closely on the heel of demand, I felt no doubt whatever that as soon as central stations were ready for the meters, the meters would be ready for them. This forecast has been fully verified by the fact; and from the exhibit we have had placed before us to-night, coupled with the indication afforded by the Patent Office of an extraordinary amount of inventive activity concentrated on this subject, it looks almost as if the demand was not merely about to be supplied, but supplied super-abundantly. Meanwhile, although we have got several kinds of meters, all of them reflecting the highest credit on the ingenuity of the inventors, if I single out any one of these as especially deserving of mention for felicity of idea, and exquisite development of the idea, I should certainly have to mention the exceedingly beautiful meter of Prof. Forbes.

"I do not remember how many it possesses of the thirteen qualifications which Prof. Forbes told us should be possessed by an ideal meter, but certainly in his they will count up to a goodly number. I believe I am right in thinking that it was the first of those meters which measure both continuous and alternating currents. How surprisingly the supposed disabilities of alternating currents have melted away in the presence of that all-solving sun—necessity. Now we have not only motor-meters, but also electrolytic meters for alternating currents. Truly, 'All precious things discovered late, to those who seek them issue forth'; and at last I suppose we shall have our ideal meter.

"The things most lacking in the best of the meters shown to-night are want of range and want of simplicity. Range and simplicity were two of Prof. Forbes's thirteen points. To put the first of these into figures, I should say that the range should be at least 1 to 100, instead of 1 to 15 or 20, the range of those meters which so far have the greatest number of the 13 points. In respect of simplicity, and consequently of cost, I think all the motor meters leave much to be desired.

"The experimental meter which Prof. Forbes showed us last, if he can conquer the difficulties of detail that stand in the way of its being made a practical instrument, as he has conquered the seemingly as great difficulties of detail in the case of his windmill meter, would, I think, score most of the thirteen points. Certainly it would have the very great merit of simplicity and wide range, and I earnestly hope that he will persist in the endeavour to perfect it."

* It was pointed out, however, that Mr. Crompton had said that the single clock-meter *was* used. Prof. Forbes was pleased to find he had misunderstood Mr. Crompton.

NOTES ON THE DESIGN OF ELECTRIC MOTORS.*

BY ALBION T. SNELL.

DISCUSSION.

(Concluded from page 102.)

Prof. W. E. Ayrton: In reference to Mr. Esson's very pertinent question, I would say that the lead—that is to say, the actual position of the brushes—was unaltered during the time of the experiment; as a matter of fact it cannot be altered. The Immisch motor does not require any alteration of lead with variable current. The armature was rotated in the different experiments in both ways, so that any advantage that could be obtained by there being a lead would have been obtained for the motor when the armature was rotated one way, and for the dynamo when it was rotated the other, and the numbers that it would be right to take would be the highest values of back E.M.F. in the motor when rotated one way, and the highest values of forward E.M.F. for the dynamo when rotated the other way. The highest values of forward E.M.F. are lower than those of the back E.M.F. when the armature is running the other way. There is no question, therefore, as to the lead being more advantageous in the one case than in the other—the lead was suitable for a machine as a motor and equally suitable for a machine as a dynamo: that answers Mr. Esson's question No. 1. Now, with reference to Mr. Esson's question No. 2. He said on the last occasion "with a current flowing in the same direction through the machine, the armature is revolved, of course, in the opposite direction, the brushes having the tips rounded so that their ends do not turn up." We did not round the tips of our brushes, because that was not necessary, but otherwise we did exactly what Mr. Esson described, and I can only say that we found the result to be as I have already described. I do not mean to say that I neglect for a moment what Mr. Esson has said to-night about self-induction, but he now adds, "you ought to have a correction to make your results equal to mine." All I can say is that we did exactly what is said in the *Electrical Engineer*, and we did not find that in each case $V_1 + CR = V_2 - CR$, as he did, but, on the contrary, we found the $V_1 + CR$ was different from $V_2 - CR$, the result for the dynamo being less than the result for the motor. What he now remarks is, however, perfectly true, that there might have been a term added for self-induction, but does he not rather uphold that self-induction is of no consequence in these machines? He said last time, "I have concluded from this that the effect of self-induction might

* Paper read at the City and Guilds of London Institute Old Students' Association, January 30.

Digitized by Google

be neglected." Well, cannot we conclude that the self-induction might be neglected?

Mr. W. B. Esson: No.

Prof. W. E. Ayrton: Of course I do not want to in any way evade the question by a little bit of special pleading, for I value Mr. Esson's suggestions far too highly to attempt to evade them by any mere special pleading, but, if you will allow, I will put down the gist of Mr. Esson's remarks that he has just made. If there be an effect of self-induction, then you may say that in the dynamo $E = V + C(R + r)$, and in the motor $V = E - C(R + r)$. Well, now, if r has an important value, then in order to get E from V, which, of course, is the thing you measure, you ought to add something larger than C R in the case of a dynamo, and you ought to subtract something larger than C R from V to get E in the case of a motor. No doubt, so far, what he says is correct, that we ought to have added something larger than C R to get E in the case of a dynamo, and we ought to have subtracted something larger than C R from V to get the result in the case of a motor. That is, no doubt, true, and that is exactly what Prof. Perry and I pointed out in our original paper years ago, but Mr. Esson, on the other hand, did not follow that course when he made his experiments, and he concluded, to use his own words, that the armature cannot, by any physical possibility, help the field in the motor. I do not think he has proved his point, and possibly he has the same opinion about our experiments. I think, really, that the proper way, with reference to what Dr. Walmsley has written down, is not to express the loss of power in a dynamo or motor as a loss of potential difference, or E.M.F; I think that is rather misleading. I did not make the mistake which Dr. Walmsley thought might have been made. I did not imagine that Mr. Snell meant by E_m what is commonly called the back E.M.F. of the motor. He means a kind of fictitious back E.M.F., but I think it is a mistake to introduce this fictitious back E M.F., this less E.M.F. We do not know that there is any less E.M.F. The proper way is, I believe, to write the thing as we put it in our paper some seven years ago—that is, that the power supplied to the motor, C V, is used up in two ways. It is first divided into two parts, C^2R and Cv. C^2R is the amount of watts that is immediately turned into heat. Apparently, that term may also be divided into two parts—(1) $C^2 R_0$, where R_0 is the ordinary resistance of the armature at rest; and (2) $C^2\,np$, where n is the speed of rotation, and p a term depending on the self-induction of the armature. Lastly, there is Cv, which is *wholly* spent in producing mechanical power. This power is employed partly in overcoming the mechanical friction of the bearings; partly in overcoming the magnetic friction due to Foucault currents; and, lastly, in doing useful work on the tool driven by the motor. That seems to me the proper way to divide up the thing, and not to introduce an imaginary E.M.F., because really we have no proof that there is any such negative E.M.F. existing. A certain number of watts are used up in two ways in a motor, and loss is produced. The heat due to magnetic friction is really of exactly the same kind as the heat due to mechanical friction. In both cases motion is produced, and that motion is employed in grinding metal against metal, and in the other case it is simply used in grinding metal against a possible ether resistance. But in $C^2 R_0$ you have a direct conversion of electric energy to heat. That seems to me better than expressing the loss as an imaginary E.M.F., which is to be subtracted from the true back E.M.F. of the motor. I do not object because I think Mr. Snell meant E_m to stand for the true back E.M.F. for a moment.

Mr. A. T. Snell: No, no.

Prof. Ayrton: I do not object to that; but what I do object to is the introduction of an imaginary loss of E.M.F., which I do not believe exists at all. You use the power of the motor in foolish ways. It is your fault, and not that of the motor, which you are using badly, if by making metal grind against metal, or metal grind against ether friction, you put a brake upon it, and say it is a marvellously bad motor, because the brake has been put on by bad engineering or bad lamination, and so mechanical work is wasted in heat. It may be all one to you whether you have lost the money paid you in receipt of a debt or whether you never received payment, but it is not by any means all the same to the debtor. So it may be all one, as far as the tool is concerned, whether some of the mechanical power developed by the motor has been wasted, or whether that amount of mechanical power was never produced at all; but surely it is very different theory to the electrical engineer, seeing that the deficit must be grappled with in totally different ways.

Mr. Albion T. Snell, in reply, said: Mr. President, and gentlemen, my primary object in writing this paper was to elicit discussion, and I do not think I have failed in that object, for both my mathematics and practical results have certainly been handled quite as roughly as I wished them to be, and I think this debate has given us some very important fresh data which will set us all thinking, and probably enable us practical men to make better machines in the future. But I had also a second reason, and that was to bring before this association a new departure in the method of motor design—that is, that a motor should be designed primarily with reference to the torque, and not with reference to the horse-power. I am sorry to say that this point has been missed, and the discussion has not turned upon what I regard as a very important feature in motor design, but it has rather turned upon the reversibility of the dynamo. My mathematics all through, I should state, are intended more to be of a graphical character than strict mathematics according to the Cambridge view, and I fully agree with Prof. Ayrton that these equations will not stand with mathematicians, but to practical men, with all deference to Prof. Ayrton, I say that this equation *here* is of more importance than *these* equations (Prof. Ayrton's analytical expressions for losses in motor), for the simple reason that we use *these*, but cannot use the others. When we make a motor, the most important point is to know where we lose most of our energy, whether by ohmic resistance, or by friction in the bearings, hysteresis, or Foucault currents. The formula here (board) gives me exactly the loss. I was under the impression that the term $\frac{\text{B.H.P.}\ 746}{n\,c}$ did not appear in Prof. Ayrton's paper, but I am pleased to hear that I have been forestalled in it. I fully recognise the priority of the term. I have had such an amount of criticism that I hardly know where to begin, but I think I will take Prof. Ayrton's speech to commence with. I will first of all say a few words on the design of motors with reference to the current. You know there is a certain current which a motor will work at without undue heating; that we have primarily to determine, and with that current we can do a definite number of foot-pounds per revolution. If a motor is designed to run at, say, 100 volts, and it comes out at 80 volts, it is not of much importance, we merely get less power out of it, but if it has to run at a higher current the motor is useless because it will overheat; and in a dynamo, what we have to look to is the number of volts, because we are going to run lamps at a certain voltage. Thus we do not care so much about the number of amperes, but look primarily to the E.M.F. on the terminals. Mr. Esson has certainly brought forward a very strong view of the opposite side of the main question, but I think that he has rather overlooked certain parts of my paper, particularly in the commencement, in which I practically concede to him almost the whole that he has argued to-night (Mr. Esson, hear, hear). I said distinctly, to begin with, that in large dynamos which were used as motors the same results will not be obtained as with small motors used as dynamos. Now, almost the whole of the experiments which I referred to have been made with machines designed expressly as motors, and not dynamos; but as showing how the armature ran as a motor, compared with the same armature ran as a dynamo, I made some experiments a few days ago on a machine expressly designed as a dynamo. [Formula shown on board.] I take the well-known formula $Ea = K\,\mu\,a\ Nt\,A$, which gives the internal E.M.F. in terms of a constant, the number of turns of wire, the cross-section of the armature, and the value of the magnetism per square inch. The values of the internal E.M.F.'s are severally 381·2 + 302·8 volts, $Nt = 576$, and $A = 59$ square inches. On calculating you will find that the value of the induction in the dynamo is 14 Kapp lines, in the motor it is 14·9. Where does the extra magnetism shown by that formula come from? If the views that Prof. Ayrton and myself have put forward do not account for that extra magnetism, I am fairly at a loss to account for it. I unfortunately, have no mathematical data to prove where this extra magnetism is gained, but it does exist, I am sure, and the experiments that Prof. Ayrton has made with the assistance of his students during the last few days with one of the Immisch motors, fully confirm the experiments that I have made during the last three or four years. Mr. Gümpel has pointed out that although all engines are capable of being used as air-compressors and pumps, yet they by no means make good pumps or good air-compressors. That is obvious, I think, and the same thing really applies to a dynamo and motor. A dynamo may be a good motor, and a good motor may be a very fair dynamo, but it does not follow by any means. Prof. Ayrton made some remarks with reference to self-induction in the armature tending to increase the lead in the dynamo, and decrease the lead in the motor; well, I find that, almost without exception, the lead in a motor is less than the lead in a dynamo, that is, for the same machine, and the difference in machines of the Manchester type is oftentimes so marked that in the dynamo there will be a lead of 30deg., whereas in the motor there will only be a lead of 5deg. Unfortunately, we cannot get inside a dynamo, and we do not know how the lines of force are distributed, but I will try and explain it this way. [Explains on board diagrams showing change of resultant pole with the position of brushes.] The difficulty would appear to be that the position of the resultant axis of magnetism of the armature varies with every alteration of current. If the field, for instance, is increased very much, the pole probably would be very far forward, and right underneath the corner of the pole of the field; but if the current is decreased the chances are it will go back, or *vice versa*. Prof. Ayrton was kind enough to call attention to an oversight in my paper in the expression that I have put for the torque. My equation—it is really in C.G.S. units—is quite correct as it stands, I think. At any rate, I know it appears in all the text-books, and if I am wrong the text-books are wrong. In my paper I dealt with foot-pounds and Kapp lines, and, therefore, I ought to put the constant down; but Dr. Walmsley has been kind enough to write it out, and I will put it on the board. [Equation put on board.]

$$T = \frac{Ca\ Nt\ Za}{2\,\pi} \cdot 00004432.$$

That is the equation I used, but I forget what the constant is. Prof. Ayrton raised another point as to making the magnetic field relatively stronger as the size of the machine is increased. Well, experience seems to point to the fact that as a machine gets larger it is advantageous to increase the size of the field, but I am willing to concede that the principal reason is that of cost. A large armature is very costly, and as a rule, with big machines, the question of weight does not come in, so that it is better to make a small armature with a relatively powerful field than it is to make one with a large armature and a weak field.

Prof. Ayrton: You have no reason except the cost?

Mr. A. T. Snell: Practically none. But I would say that the larger the machine the greater is the leakage, the leakage through space is greater, and the result is that we have a greater difficulty in maintaining a given concentration of magnetism in the armature. Suppose we want to realise, say, 16,000 C.G.S. units in the armature, we should have to put on an increased field of 10 per cent., it may be, over what we should use in the case of a 1 or 2 h.p. machine. I am thinking now of about a 50 h.p. machine. But I can state this most distinctly, that in all cases where a dynamo and motor have to be designed with a given armature, a very much smaller field can be used for the *motor* than for the

Digitized by Google

dynamo. I am not sufficient mathematician to give you the reasons for this proportion. If we could thoroughly analyse the very important equations that Prof. Ayrton has just now put on the board, we could find the value of the constants in the usual way, but the matter is practically an extremely difficult one, and that is why I have dealt with the matter in a practical rather than a strictly mathematical manner. With reference to the use of the quantity $\frac{\text{B.H.P. } 746}{n c}$; it is, you can see at once, really an E M.F. The brake horse-power × 746 brings the total quantity into watts. We do not know what the E.M.F. is there at the time, but we do know what the current is, and if we divide by this current we must have a quantity of the order of volts. I prefer to call it the *effective* E.M.F. of the motor, and that is what we want. The theoretical back E.M.F. is not of so much use to us as the actual effective number of volts; if we have that, we have the practical measure of our machine. I would like to cordially thank Mr. Reckenzaun for the interesting speech that he made this evening, for the strong support that he has given to the views that I have been advocating, and I am pleased to find that a dynamo in one case required 60 per cent. more speed than it did as a motor. This thoroughly bears out the results of my experience. I shall be very pleased to take the hints that have been given to me this evening about the alterations in the equations and so on, and I am also obliged to Mr. Kilgour for his remarks upon the subject of efficiency. I did not quite catch the pith of his remarks, but I think I know what he meant. The diagram is for a Sprague motor, and I hope Mr. Sprague will pardon me for saying that his motor is not efficient, but the curve of the diagram shows it thus. [Diagram on board explained.] The machine should be designed so that although we do not take maximum work out of the motor, the work is done at a more efficient part of the curve. This is a most important point in the design. I hope before long to have an opportunity of putting before you what I would call the curves for a normal Immisch motor. I have only to thank you for the kind manner in which you have received my paper, and I shall have very much pleasure in taking advantage of the criticisms that have been so liberally given.

COMPANIES' MEETINGS.

TAUNTON ELECTRIC LIGHTING COMPANY.

The second annual general meeting of the shareholders of the Taunton Electric Lighting Company, Limited, was held at the Castle Hotel, Taunton, on Monday evening. Mr. W. H. Fowler, J.P., the chairman of the directors, presided.

The **Chairman** read the following report and balance-sheet: "The number of shares allotted is 951, on which the sum of £4,750 has been received. The accounts for the year show a profit of £355. 18s. 2d. Your Directors recommend that a dividend of 6 per cent. be paid free of income-tax. This will take £272. 0s. 5d. The balance carried on for a reserve and depreciation account, including the amount from 1887, will be £207. 13s. 9d. In addition to the Taunton business, the Company has carried out temporary installations in Bristol, Bath, and Exeter. Deputations from various places have visited Taunton during the past year, for the purpose of inspecting the Company's works, and the lighting arrangements of the town; the general testimony being that it is the most successful installation in central station lighting yet carried out in the United Kingdom. The machinery has been maintained in excellent working order, those portions of it which are continuously wearing out being made good and charged to income account. The present engines are rather extravagant in their consumption of fuel; your Directors therefore recommend that, as the demand for private lighting is rapidly increasing, engines of the highest possible efficiency should now be put down, using the present engines as duplicate plant only. This will effect a saving of nearly £200 per annum in coal, water, and oil. It is desirable also to largely increase the electrical plant to enable your Directors to cope with the increasing business, and they therefore propose to offer, at par, the remaining share capital of the Company. Should the applications for shares exceed the number offered, the present shareholders will receive priority of allotment in proportion to the number of shares they now hold. Three of the Directors retire by rotation, and are eligible for re-election—namely, Messrs. Bale, Withycombe, and Potter. The auditor, Mr. Albert Goodman, retires, but is eligible for re-election, and offers himself accordingly. Balance-sheet: Capital Account—Receipts—To share capital—954 shares at £5 each, £4,770; less calls unpaid, £20; total, £4,570; debentures, £3,000; balance, £129. 0s. 10d.; £7,879. 0s. 10d. Expenditure: Plant, machinery, etc, including business taken off, apparatus, formation, and preliminary expenses, £7,879. 0s. 10d.; balance brought down, £129. 0s. 10d. Income Account: Income—Rents for lamps; electrical apparatus, etc., sold; installations carried out, £2,471. 14s. 10d.; stock in hand December 31, 1888, £340. 19s. 10d.; £2,812. 14s. 8d. Expenditure: New apparatus and renewals, £541. 17s. 10d.; wages and salaries, £529. 18s. 3d.; hire of plant, etc, for temporary installations, £261. 19s.; Directors' fees, £37. 16s.; interest on debentures, £146. 1s. 9d.; bank interest, £30. 3s., making with other items a total of £2,305. 1s. 8d.; stock in hand December 31, 1887, £151. 14s. 9d.; balance, being profit, £355. 18s. 3d.; £2,812. 14s. 8d. Assets—rents and accounts for installations, due, £1,203. 6s. 6d.; stock in trade, £340. 19s. 10d.; balance from capital account, £129. 0s. 10d.; £1,673. 7s. 2d. Liabilities—Balance due to bank, £617. 19s. 1d.; liabilities, £575. 13s. 11d.; balance, £479. 14s. 2d.; £1,673. 7s. 2d. Profit and loss account—profit, year ending December 31, 1887, £315. 15s. 5d.; balance brought down, £123. 15s. 11d., profit, year ending December 31, 1888, £355. 18s. 3d.; £479. 14s. 2d. Dividends (5 per cent.) paid for 1887, £191. 19s. 6d.; balance, £123. 15s. 11d.; total, £315. 15s. 5d.; dividend at 6 per cent., £272. 0s. 5d.; balance carried forward, £207. 13s. 9d.; £479. 14s. 2d. Cash account—receipts—balance at the bank, December 31st, 1887, £376. 8s. 9d.; receipts—capital account—shares, £4,750; less, December 31, 1887, £4,365, £385; income account, £1,760. 3s. 10d.; balance due to bank, £617. 19s. 1d.; £3,139. 11s. 8d. Payments—Cheques not presented, December 31, 1887, £364. 12s. 11d.; liabilities due December 31, 1887, £92. 13s. 8d.; expenditure—capital account, £7,879. 0s. 10d.; less, December 31, 1887, £7,118. 3s.; £760. 17s. 10d.; expenditure—income account, £2,305. 1s. 8d.; less, unpaid, £575. 13s. 11d., £1,729. 7s. 9d.; dividends paid, £191. 19s. 6d.; £3,139. 11s. 8d."

The **Chairman**, in proposing the adoption of the report, said it was a very satisfactory thing that at the end of their second year they were able to pay an increased dividend, and at the same time to make proper provision for depreciation of plant, and for any extraordinary expenditure that might come upon them. They had carried forward a sum of £207. 13s. 7d., and as the machinery was kept at its highest efficiency he thought they could consider they were fully justified in paying an increased dividend. At the same time it was absolutely necessary to enlarge their plant, and they would be unable to do so unless they had further capital from the general public. If others were prepared to back him up, he would put a further sum of £500 in the Company, because he was fully satisfied that the thing would be a success, provided they made it large enough to meet the demands of the general public. He thought they were all greatly indebted to their managing director (Mr. Massingham) for the way in which he had attended to the Company's interests and the supervision of the works. He then moved that a dividend of 6 per cent. be paid free of income-tax to be payable on the 13th inst.

Mr. Lance seconded the report.

Mr. Massingham, in moving the re-election of Mr. Bale, said it gave him great pleasure to ask the shareholders to re-elect that gentlemen, because Mr. Bale was a man of very enlightened views. He showed that by becoming a shareholder in the Electric Lighting Company, although he was at the same time a large shareholder in the rival concern in the town (the Gas Company), he had seen that there was plenty of room for the electric light in Taunton, and he had supported that company from the beginning. Referring to the report he said all would agree with the Chairman that is was a very satisfactory and encouraging one, because they would find that the revenue had increased by 45 per cent., and owing to that increase they were able to pay an additional one per cent. dividend. He thought it very probable that next year they would be able to pay 7 per cent. dividend because there was a large number of customers awaiting to be supplied, a demand which could not be met at present owing to the smallness of the plant. Until they had got better and larger plant they would not be able to supply all that was demanded. They started three years ago with one dynamo, now they had six, and larger ones were required. New ones would be provided, and the old ones still be used when necessary, in case, for instance, of a breakdown. Breakdowns in Taunton hitherto had fortunately been very "few and far between." Everyone knew that this, like all other inventions, were liable to accidents. Breakdowns occurred in older and well-tried concerns. He instanced the case of a town in Wales, where the whole town was thrown into complete darkness owing to an explosion in the gas works. He believed that theirs was the most satisfactory installation in England. Among other gratifying features was the proposal to largely increase the plant and lay down more efficient engines. The engines now used had given satisfaction, but they were not of the highest and best type obtainable, and while they were very serviceable when the supply was not so great, they had reached a state of success that enabled them to buy better ones. He thought the purchase of new machines would result in the saving of £200 a year, and that meant a dividend of 4 per cent. on the capital. He went on to state that the greater the supply the cheaper would be the cost of the production, and as the demand increased they would, doubtless, be able to reduce the price to the consumer. He was pleased to hear that the Chairman had intimated his willingness to purchase other shares in the Company, and he thought from the applications that they had had they would have little difficulty in raising the capital they proposed. One matter he wished to refer to was the standards from which the arc lamps were suspended in the streets of Taunton. He thought the town authorities ought to erect better ones now, after the pattern of those to be erected at Bath. The present standards were erected only as temporary ones while the electric light was being tried as an experiment. The standards answered their purpose very well then, but now that the electric light had passed from its experimental stage and was proved to be a success, he thought permanent ones should be erected. He hoped the Corporation would see the advisability of providing more suitable standards.

Mr. A. Chapman seconded the re-election of Mr. Bale. He had no doubt that Mr. Bale would continue in the future to be the same useful member on the Board of Directors that he had been in the past.

The motion was carried.

Mr. Bale returned thanks. In doing so, he said the success of the undertaking in which they had embarked had been secured in a great measure by the very conscientious and unremittent attention which the Directors generally had given to the work. It had been a pleasure to him to work with them.

Mr. A. Steevens proposed the re-election of Mr. Withycombe. He said that Mr. Withycombe had shown his confidence in the undertaking by having his hotel lighted at considerable expense by electricity. He was sure, from what they knew of him in all relations of life, and especially as a business man, it was highly desirable that he should be re-elected on the Board of Directors.

Digitized by Google

Mr. Bale seconded the motion, which was carried, and **Mr. Withycombe** suitably responded.

Mr. A. Goodman proposed the re-election of Mr. Potter, which was seconded by **Mr. Down,** and carried.

Mr. Potter, in returning thanks, said they might congratulate themselves on the fact of their continued existence. The report presented at that meeting went to discredit the prognostications made at the birth of the electric light movement that it was such a weak and sickly concern that they could not possibly exist. Many of their kind friends, with the kindest possible intentions, advised them not to invest in that Company, and have nothing to do with the work whose existence was so precarious. There were some grounds for the fears of their friends, perhaps, because some previous undertakings of the kind had not had a very prosperous life. Their Company, however, had proved beyond a doubt that the new illuminant could be made a prosperous, good, and paying concern. There was another thing they might congratulate themselves on, and that was that a company that had adopted the Thomson-Houston system never ended in disaster or disgrace. Although the present system was not a perfect one—it was not claimed for it that it was—they claimed that it was the most perfect system yet introduced into this country, and they had proof of this in the fact that larger towns than Taunton, such as Exeter and Bath, had adopted the same system with success. That it was successful in Taunton no one would attempt to deny now. The first year of their existence they not only claimed but fairly earned a dividend of 5 per cent. That dividend was not taken out of the share capital, as had been alleged, but had been fairly obtained from the profits. This year they had been able to declare a dividend of 6 per cent., an event unprecedented in the history of electric lighting in this country. Their position, now, was just this. They had outgrown their premises, and they had an increased demand for the light, which rendered it necessary that they should seek larger premises, and lay down additional plant, and to do this it was necessary that the remaining share capital should be obtained. If this were done, there was every probability of the dividend being increased next year. But their prosperity had not been purchased by loss to any other company. So far as he was aware the introduction of electric light had been attended by nothing but good. It had unquestionably benefited the town. It had earned for the town a reputation which nothing had previously given it; it had drawn public attention to the town, and this had resulted in the people finding out what a desirable place of residence it was, and he believed that at the present time there were fewer villa residences to let in the neighbourhood of Taunton than there had been for the last 10 or 15 years. He hoped, in conclusion, that every shareholder would secure the additional capital being taken up, and he was sure that in the future, as in the past, success would be assured.

Mr. Bale proposed the re-election of Mr. Goodman as auditor, which was seconded by **Mr. Massingham.** The latter thought the Company had been exceedingly fortunate in securing Mr. Goodman as auditor. From the fact that Mr. Goodman held the position of Director on the Taunton Gas Company he was exceptionally well qualified to audit the accounts. If Mr. Goodman were their bitterest enemy instead of their greatest friend, he could not be more careful and searching in looking over the accounts.

The resolution having been carried, **Mr. Goodman** returned thanks and spoke of the advantages that would accrue from the increased capital being obtained.

Mr. A. Goodman moved a vote of thanks to the Directors, which was seconded by **Mr. Waldegrave,** and responded to by the **Chairman.**

Mr. Potter moved a vote of thanks to the Chairman, **Mr. A. Lewis** seconded the motion, and the **Chairman** responded, this bringing the meeting to a close.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The ordinary general half-yearly meeting of the Anglo-American Telegraph Company, Limited, was held on Friday at Winchester-house, Old Broad-street.

Viscount Monck, who presided, in moving the adoption of the report, said that during the past half-year they had had, as the shareholders were aware, a good many repairs effected in their cables. They had been executed entirely by the Company's own steamer, and, therefore, at first cost. Their deep-sea cables had been all in good order except the original French cable of 1869, upon which the Company had had very considerable repairs to make. That was the oldest cable now transacting business in the Atlantic, and it was put into thorough working order. As to the expenditure which had been incurred, independently of repairs and renewal of cable, the board had endeavoured to reduce it as much as possible, and if the shareholders would take the trouble of comparing two or three of the annual reports and examining the details of the outlay, they would find that it was but a very small portion of the expenditure over which the Directors could exercise any direct control. They had debited themselves with £2,000, the estimated cost of the law suit now pending between the Company and the Paris and New York Telegraph Company—an item which would not again appear in the accounts. As to the Company's income and prospects, if they did not give rise to any effusive jubilations, they were at all events more satisfactory than had been the case at recent meetings. He then referred at some length to the experiment of a sixpenny word rate, which, he said, had been tried for a year and proved conclusively to everyone concerned that in the present condition of Atlantic telegraphy such a tariff would not pay. They had therefore increased the rate to 1s. a word. The experience they had had of the latter rate was not sufficiently extensive to enable them to form an opinion as to whether it would be satisfactory or not; but this he could say—that up to the present time it had not been unsatisfactory. At any rate, whatever might be the result, he hoped that by the exercise of moderation and forbearance to their adversaries they would ultimately fix on a tariff which, without bringing to the shareholders such large returns as would induce further competition, would yield a moderate and remunerative dividend on the money they had invested in the concern.

The **Marquis of Tweeddale** seconded the motion.

Mr. Smith (York), **Mr. Jackson,** and **Mr. Guesdon,** congratulated the Directors on the favourable condition and prospects of the Company, and on the memorandum of agreement which had been entered into between the Company and its rivals, whereby peace was established for at least 12 months, with the probability at the end of that period of a permanent working understanding being arrived at.

The **Chairman,** in reply to a question, said he could not state what would be the probable "life" of the 1869 cable; but wherever it had been picked up for repair in favourable conditions at the bottom of the sea, it was found to be as good as it was when originally laid.

The report was adopted, and the retiring Directors and Auditors were re-elected.

GERMAN UNION TELEGRAPH AND TRUST COMPANY.

The eighteenth and final ordinary general meeting of the German Union Telegraph and Trust Company, Limited, was held on Wednesday last at Winchester House, Sir James Anderson presiding.

The **Chairman** said that he was somewhat disappointed that the hopes held out at the last meeting of the shares getting very nearly par had not been fulfilled. Since then, in December, they had broken the cable, the cost to repair which had been no less than £7,684, which, of course, had to come off the payment on shares. He had been startled to find the money sent over to them in marks, and an allowance of 5d. in the pound had to be agreed to in consequence. They would receive, he believed, £7. 6s. per £10 share, and he hoped they would ultimately get about £2. 4s. 9d. more, to make a total of £9. 10s 9d.—that is, if affairs turned out as they expected. As this was the final meeting he had nothing further to do than to move the adoption of the report and balance-sheet for the period ending January 25 last, which showed receipts amounting to £754. 5s., which, with a balance of £156. 3s. 5d. brought forward, made a total of £910. 8s. 5d., the expenses of the same period being £909. 9s. 7d., of which sum £750 was provided by the German Union Company of Berlin, the balance to be handed to the liquidators.

Mr. Hermann Gustav Erichsen seconded the motion, which was carried.

The **Chairman** then said he was sorry the German Government had taken the business from them, but all they could do was to submit, although he believed the Company would otherwise have been successful.

An extraordinary general meeting was afterwards held, when the **Chairman** moved, and **Mr. Erichsen** seconded: "That the resolution passed by the extraordinary general meeting on January 22, 1889, 'That this company be wound-up voluntarily,' be, and the same is hereby confirmed."

The motion was carried without discussion, with one dissentient.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for the past week amounted to £4,796.

Great Northern Telegraph Company.—The receipts for the month of January amounted to £22,400.

West Coast of America Telegraph Company.—The traffic receipts of this Company for the month of January amounted to £6,125.

Eastern Telegraph Company.—The receipts of this Company for January were £65,835, as against £56,164 for the same period of 1888, or an increase of £9,671.

Eastern Extension Telegraph Company.—This Company's traffic receipts for the month of January were £41,820, as against £39,878 for the same period of 1888.

Western and Brazilian Telegraph Company.—The receipts of this Company, after deducting the "fifth" payable to the London Platino-Brazilian Company, were £3,691.

Direct Spanish Telegraph Company.—The receipts of this Company for the month of January are estimated at £1.880, as against £1,943 in the corresponding period of last year.

Telegraph Construction and Maintenance Company.—Including the interim dividend of 5 per cent., the Directors of this Company propose to pay 20 per cent. for the past year.

West India and Panama Telegraph Company.—The receipts of this Company for the half-month ended January 31 show a decrease of £509, as compared with the corresponding period.

Taunton Electric Lighting Company.—A dividend of 6 per cent. has been declared, as against 5 per cent. last year. The Directors ask for more capital in order that they may give attention to the question of domestic lighting.

National Telephone Company, Limited.—The Directors of this Company have declared a dividend for the past half-year at the rate of 4 per cent. per annum, leaving a balance to be carried forward of £10,399, of which £3,500 is set aside against an outstanding claim.

Digitized by Google

London and Provincial Lighting Company.—Mr. Justice Chitty has appointed Mr. Lionel H. Lemon, chartered accountant, official liquidator of the London and Provincial Electric Lighting and Power Generating Company, Limited, in place of Mr. W. Lott Grimwade.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during January was 3,922, estimated to produce £3,100, against 4,064 messages, producing £3,366. The traffic receipts for October, estimated at £3,300, realised £3,316.

Crompton and Co., Limited.—The Directors of this Company, at their meeting held on the 31st ult., declared an interim dividend of 7 per cent. per annum upon the preference shares of this Company for the five months ending December 31 last. They have also decided to pay at the same time the 4 per cent. interest to same date upon the amounts paid in full in advance of calls.

Companies of the Month.—The following electrical companies were registered during the past month :

Electro-Galvanic Machine Company, £1 shares	3,500
Miners' Lamp Electric Lighting Company, £5 shares	3,000
Maxim-Weston Electric Company, 3s. shares	75,000
Newcastle-upon-Tyne Electric Supply Company, £5 shares...	50,000
Newcastle and District Electric Lighting Company, £10 shares	50,000

India Rubber, Gutta Percha, and Telegraph Works Company, Limited.—The report of the Directors of this Company for the year ending December 31 last show the net profit for the past year to be £57,157. 14s. 2d. Adding £9,530. 3s. 5d. brought forward, and deducting £20,800 interim dividend paid in July, there remains a disposable balance of £45,887. 17s. 7d. The Directors recommend the distribution of a dividend of 10s. per share, free of income-tax, amounting to £20,800, making, with the interim dividend, a total payment for the year of 10 per cent., and leaving £25,087. 17s. 7d. to be carried forward. The Company's general business continues to increase; but competition is as keen as ever, and only a low rate of profit can be made. The submarine cable work of the year has consisted of several items of small amount. The works are now occupied in the manufacture of about 800 miles for the Eastern and South African Telegraph Company, to be laid in May on the West Coast of Africa, in extension of the West African Telegraph Company's cables manufactured and laid by this Company. The Company's works and machinery are in efficient working order. Mr. Scott and Mr. Henderson, the Directors retiring by rotation, offer themselves for re-election. The Auditor, Mr. Weise, retires, and is re-eligible.

PROVISIONAL PATENTS, 1889.

DECEMBER 11, 1888.

18,035A. **An improved ampere gauge and connections, parts of which are applicable to other electric appliances.** Sir William Thomson, 115, St. Vincent-street, Glasgow. [Note. This application having been originally included in No. 18,035, dated 11th December, 1888, takes, under Patents Rule 23, that date.]

18,035B. **Improved apparatus for continuously measuring and recording potentials or currents.** Sir William Thomson, 115, St. Vincent-street, Glasgow. [Note. This application having been orginally included in No. 18,035, dated 11th December, 1888, takes, under Patents Rule 23, that date.]

18,035C. **Apparatus for regulating electric potentials or currents.** Sir William Thomson, 115, St. Vincent-street, Glasgow. [Note. This application having been originally included in No. 18,035, dated 11th December, 1888, takes, under Patents Rule 23, that date.]

JANUARY 28, 1889.

1480. **Electric meters and motors.** Arthur Wright, George Herbert Alderton, and George Joseph Philpott, 3, Clement's-road, Preston Park, Brighton.

1500. **Applying electric light to cycles.** Richard Martin Presland, Lyme-grove, Mare-street, Hackney, and Ernest Henry Glover, 40, Selborne-road, Walthamstow, Essex.

1510. **Improvements in electrical transformers.** William Morris Mordey, 46, Lincoln's-inn-fields, London, W.C.

1535. **Improvements in the construction and working of dynamos.** Illius Augustus Timmis, 2, Great George-street, Westminster, S.W.

1537. **Improvements in or relating to electric incandescent lighting.** Alfred Julius Boult, 323, High Holborn, Middlesex. (Stefan Doubrava, Austria.)

JANUARY 29.

1573 **Certain improvements in electro-magnetic transmitters (port-electrics).** Cecil Urquhart Fisher, 1, Furnival-street, Holborn. (John Thomas Williams, United States.) (Complete specification.)

1611. **Improvements relating to multiplex electric telegraphy.** Mark Wesley Dewey, 45, Southampton-buildings, London. (Complete specification.)

JANUARY 30.

1673. **Improvements in the construction of secondary batteries.** Gustave Philippart, 6, Bream's-buildings, London, E.C.

1677. **An automatic electric switch.** George Herbert Whittingham, 323, High Holborn. (Complete specification.)

JANUARY 31.

1757. **A new or improved automatic coin-freed machine for giving electric shocks.** Joseph Mason, 76, Chancery-lane, London, W.C.

1768. **Automatic circuit changer for electric currents.** Philipp von Hertling, 89, Chancery-lane, London, W.C.

1775. **Means and appliances for holding electric accumulators on vehicles.** Michael Radcliffe Ward, 9, Warwick-street, Regent-street, London.

FEBRUARY 1.

1823. **Improvements constituting a combined translator and indicator for telephonic purposes, part of such improvements being applicable also, either in such combination or otherwise, for preventing or lessening induction between translators placed near together.** Alfred Coleman and Hubert Fielden Jackson, 55 and 56, Chancery-lane, London.

1827. **Improvements in telephones.** Max Salmony, 45, Southampton-buildings, London.

1839. **A combination electric arc light.** Charles Wells, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex.

1846. **Improvements in the application of heat produced from liquid hydro-carbon and water burners to the production of light and electricity, and in apparatus for this purpose.** William Boggett, 34, Southampton-buildings, London, W.C.

1850. **Improvements in the method of constructing the armatures of dynamo-electric generators and motors.** Walter Thomas Goolden and Henry Willock Ravenshaw, 46, and 47, Temple Chambers, E.C.

FEBRUARY 2.

1855. **An improvement in insulators and appliances for fixing, tightening, and retaining telegraph wires, electric wires, and other wires or ropes.** Herbert Hobson, Shepherd Rushton, and Alfred Wood, 111, Long-street, Middleton, near Manchester.

1861. **Improvements in and connected with galvanic batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

1865. **Improvements in telephone apparatus to be designated as a telephone receiver rest.** Joseph Bushell and George William Hughes, 5, Harrington-street, Liverpool.

1892. **Improvements in electric motors and means for regulating the same.** Alfred Julius Boult, 323, High Holborn, Middlesex. (Lemuel W. Serrell and Harvey L. Lufkin, United States.) (Complete specification.)

1903. **Improvements in electric motors and electric meters.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London, W.C.

1904. **Improvements in dynamos suitable especially for use as motors.** Sebastian Ziani de Ferranti and Francis Ince, 24, Southampton-buildings, London, W.C.

1911. **Reducing the difference of potential between the component wires of coils over which alternating electric currents flow or pass.** Walter Thomas Goolden and Henry Willcock Ravenshaw, 46 and 47, Temple Chambers, Temple Avenue, E.C.

SPECIFICATIONS PUBLISHED.

1888.

249. **Measuring electric currents, &c.** Roe. 8d.

1024. **Electric cells.** Pyke and Barnett. 8d.

3515. **Telephonic apparatus.** Collet. 8d.

9254. **Controlling devices operated by the thermic effects of electric currents.** Drake and others. 8d.

14,772. **Measuring electric currents.** Redfern. (Brillié). 8d.

17,668. **Electric railways.** Short. 8d.

NOTES.

Nuremberg.—The firm of Schuckert and Co. has been formed into a limited company.

Electric Dogcart in Rome.—An electric dogcart belonging to a rich American is to be seen running in the streets of Rome.

Elmore's Copper.—It is expected by the inventors that Elmore's process will work a revolution in the copper trade, almost as great as Bessemer's in the steel trade.

Royal Institution.—A paper will be read to-day, Friday, at the Royal Institution, Albemarle-street, at 9 p.m., by Prof. A. W. Rücker, on "Electrical Stress."

Books Received.—Reynier on the "Voltaic Accumulator," translated by J. A. Berly (Spon); "The Elementary Principles of Electric Lighting," by A. Campbell Swinton (Crosby Lockwood).

Farnborough.—The Empress Eugénie has just had telephonic communication established between her residence and the stables. The work was satisfactorily carried out by Mr. Julian, of Basingstoke.

Concert.—The next concert to be given by the Electro-Harmonic Society will be held in the Banquet Room of the St. James's Hall Restaurant, on Friday, February 22, when an excellent and varied programme will be given.

The Ice Carnival.—Arrangements are being made by Mr. Whiteley, the director-general of the proposed ice carnival at the Royal Albert Hall, in March, to light the hall with electric light, which will give the snowy scene a novel and beautiful effect.

Another Consolidation.—The Westinghouse Company have made another annexation, and the interests of this company are now identical with those of the United States Electric Lighting Company. There are now practically only four strong electric light companies in the field in the United States.

Electric Defence against Burglars.—Owing to the recent burglaries, the Hornsey Local Board has given permission for the police authorities to be connected to the telephones belonging to the Board now used for fire alarm purposes, thus giving direct communication at various points with the police stations.

Reading.—The plant at Reading is being put down by Messrs. Laing, Wharton, and Down on a site known as the "Island." It will consist of two Thomson-Houston dynamos of twenty 1,200 c.p. arc lamps, driven by twin 9 h.p. nominal Armington and Sims' engines. The boilers are 25 h.p. in duplicate.

Backing Electric Cars.—One of the incidental advantages experienced with electric traction for tramcars, is the ability to easily back and take up passengers. This is a point which is much appreciated by ladies and elderly persons, and is in reality an advantage in point of time to the company in picking up passengers.

Coal-Dust Furnace.—Perret's patent furnace for burning coal-dust alone in boiler furnaces is being brought out by Messrs. Bryan, Donkin and Co., Bermondsey. The firm have some 140 at work, and when coal-dust can be obtained it affords a very cheap method of obtaining power. Mr. D. K. Clark, M.I.C.E., has published a favourable report upon the furnace.

School of Electricity at Columbia.—The Columbia College (U.S.) trustees have determined to establish a post-graduate department in electrical engineering for practical work combined with theoretical training. The department will begin in a small way at first. An instructor and assistant instructor in electrical engineering will be appointed. The situation will probably be in New York city.

Electrical Church Bell.—A substitution of church and school bells is introduced by Messrs. Watt, Winnall, and Co., Atlas Works, Stepney, the action of which is electrical, and does away entirely with bell-ropes. The armature is so arranged that a stroke first one side and then the other is given in the same way as ordinary bell-ringing. The bell is also useful for factories and railway bells.

Newcastle.—Two companies have applied for permission to the Newcastle Town Council to lay down wires for electric lighting purposes. It was virtually agreed as to the arrangements between them, but details have yet to be settled after a joint meeting between the respective companies and the committee. A report will be drawn up and printed, and discussed at the next meeting of the Council.

Resume of the Brussels Exhibition.—We have received, by the courtesy of M. Bandsept, who acted as engineer-in-chief to the electrical section, a very neat and useful little book, being a *résumé* of the electrical exhibits, section 47, of the Brussels Exhibition of last year. The various exhibits and novelties are described in detail with abundant information, and illustrations are given of the principal apparatus.

Students' Meeting.—A meeting of the students of the Institution of Electrical Engineers was held last Friday evening, Mr. J. Rance, jun., A.I.E.E., in the chair. A paper was read by Mr. F. L. Horn on "Insulation Resistance," dealing with some of the practical difficulties in obtaining good insulation on electric light circuits. A discussion followed, in which Messrs. G. H. Nisbett, R. W. Paul, and Rance took part.

Visit of American Engineers.—One hundred and seventy members of the American engineers have pledged themselves to a visit to England during the Paris Exhibition, and arrangements are practically completed with the various societies in England for their entertainment. Those who have engineering concerns likely to be special objects of interest would do well to notify their permission or request of a visit to our American visitors.

"Star" Light.—The *Star* has adopted electric light as a novelty on its paper-distributing carts. A small storage battery is placed in the boot of the gig, and communicates with a 10-c.p. incandescent lamp fixed at the top of a rod which rises 3ft. or 4ft. above the highest point of the vehicle. Altogether 32 carts are employed in distributing the paper. Each accumulator carries a supply of electricity sufficient for two days, and is charged on the premises of the newspaper.

Perth.—Messrs. P. and P. Campbell, of the Perth Dye Works, have had two new alternating current dynamos fitted in connection with the electric lighting of their works, for the purpose of securing light in case of a breakdown of the large engines. Eight extra lamps have also been fitted up in the dyehouse. Messrs. Campbell have now 40 arc lamps and 100 incandescent lamps in their works. The dynamos and lamps were fitted by Messrs. Normand and Sons, Limited, Glasgow.

Digitized by Google

Austria.—A new large central station is to be erected by Ganz and Co. at Marienbad, Austria, on the Zipernowski system. The station will be near the railway station, and current will be sent 1½ miles to transformers. Two 50,000 watt machines are to be employed. There will be 35 arc lamps of 12 amperes, and 100 incandescent lamps of various candle-powers for the public streets. After midnight, the incandescent lamps only will be lighted. For private lighting there will be current for 2,500 incandescent lamps.

A Useful Fault.—A good tale of masterly inactivity comes from South Australia. A man who had got lost in the bush wandered about for four days without finding his way, when, worn out with fatigue, he came across the telegraph line. If he only knew the Morse alphabet and had an instrument! He despaired, but suddenly the brilliant idea came into his head to cut the wire and camp on the spot. A dead break was naturally at once found on the line, and telegraph linesmen were sent out to discover the fault, and happily came upon the wanderer in time to save his life.

A Small Motor.—M. Trouvé has made for experiments on aerial navigation a small motor, weighing 0·090 kilogramme, which can do two kilogrammetres of work per second, and can be contained in a cube of three centimetres' edge (1¼in.) This motor, which is made entirely of aluminium, raises itself to a height of 22 metres in a second. A one-horse motor constructed on the same plans would weigh 3·5 kilogrammes (7¾lb.). These electric motors will afford facilities for the study of the efficiencies of screw-propellers for aerial navigation, and of experiments on the best form to give them.

Electric Type Matrix.—Mr. Capehart, of Minneapolis, has brought out an electric machine which acts as a typewriter in a novel way—to produce stereos direct for printing. The machine works upon dry cardboard, and stamps upon this a perfect matrix for casting a plate, "justified" and ready for working. The movements are electrical, and it is stated that it prints faster than three good printers, besides greatly saving in type and in distribution. Thirty of these machines are being made, it is stated, at Minneapolis, and a trial of printing a newspaper direct from the matrix is to be made. It will be interesting to inspect a paper printed by this machine.

Lighting Railway Tunnels.—A new era in railway engineering has possibly been inaugurated by the complete lighting of the Hoosac Tunnel with incandescent lights. There are 650 16-c.p. lamps employed for this purpose on the Westinghouse system, with 40 miles of lead-covered cable. The railway company's objects are to afford greater safety to the travelling public, as well as to facilitate workmen's operations in the tunnel. The wiring is arranged in twenty sections of 50 volt lamps on transformer circuits. For long tunnels, such as the Mont Cenis and others, this method of lighting may prove sufficiently advantageous to be adopted for supplying light underground along the route.

The Electric Omnibus.—Further runs have been made with Radcliffe Ward's electric omnibus. This time it has gone through the City, Queen Victoria-street, Lombard-street, Cheapside, etc., to Oxford-street, and down Regent - street to the depot. Again, on last Friday, a run was made — not in the early morning, but in the thick of the forenoon traffic, through the busiest streets, taking its place amongst other vehicles, steering in and out in the ordinary daily traffic. The electric omnibus in the ordinary streets has now become the subject of an illustration in the illustrated papers. Mr. Ward and his electric bus are rapidly getting a European reputation.

St. Martin-in-the-Fields Vestry.—A letter was read from the Board of Trade at the Vestry meeting on the 7th inst., stating that their attention had been called to the fact that certain streets in this parish have been broken up for the purpose of laying electric mains by persons having no statutory powers under the Electric Lighting Acts, and that such proceedings materially increase their difficulties in dealing with applications for the privilege of supplying electricity, and that they are advised that the proceedings are illegal and undesirable. This letter was referred to the Parliamentary Committee. The Vestry was then made special, according to notice, to consider an application from the House-to-House Electric Lighting (Storage) Company for consent to a provisional order. This was granted.

Telegrams from the Continent.—In the course of the debate in the Berlin Reichstag last Friday upon the estimates of the German Postal and Telegraph Departments, Dr. von Stephan, the Postmaster-General, declared that by agreement with the British Government the *grundtaxe* of 40 pfennige hitherto charged on telegrams to England would be abolished from April 1 next, and the word rate reduced from 20 to 15 pfennige. Dr. Stephan added that direct communication would be established between the central telegraph offices in Berlin and London, and that 14 wires would be available. Negotiations having a similar object in view were proceeding with Holland and Belgium, and the establishment of direct communication between Hamburg and Liverpool was also contemplated.

Light Without Heat.—Mr. E. G. Acheson writes to the *Electrical World* pointing out that a patent was issued to him on December, 1887 (calectric generator), on the production of electric currents from heat energy, by causing the heat to enter an electric conductor, and therein acting upon it by changing lines of magnetic force, and will fully cover the production of electric energy, even up to such rapidity of oscillations as have been found necessary for light waves. There is, he thinks, no doubt but that this is the method by which energy will be caused to pass from point of production to point of consumption, and that, too, in the near future. He does not wish to discourage experiment by others, but mentions that patents on these oscillatory motions are even now broadly covered, and form the basis of continual experimental work and researches.

Prizes for Electric Light Motors.—The Council of the Society of Arts, on report of the judges —Prof. Kennedy, F.R.S., Dr. John Hopkinson, F.R.S., and Mr. Beauchamp Tower—awarded one of the society's gold medals to each of the following competitors: In Class A ("Motors in which the working agent is also produced"), for steam-engines, Messrs. Davey, Paxman, and Co., Standard Iron Works, Colchester, for an 8 h.p. compound portable engine: In Class B ("Motors to which the working agent must be applied") for engines worked by illuminating or other gas: British Gas-Engine and Engineering Company, for a 6 h.p. nominal Atkinson "Cycle" gas-engine; Messrs. Crossley Bros., Limited, for a 9 h.p. nominal "Otto" gas-engine; Messrs. Dick, Kerr, and Co., for an

Digitized by Google

8 h.p. "Griffin" gas-engine. The report of the judges in detail will be published shortly.

Alternating Tramway Motors.—A system of distribution for street tramways is proposed by Mr. W. L. Silvey, of Lima, Ohio, for use with alternate current motors. In this, high-tension currents of 2,000 volts are used with transformers to reduce the pressure to 40 or 50 volts, and by this means the advantage of the series and the parallel systems are combined. The system is an overhead one, and the transformers are placed either on posts along the track, with the carriers or trolleys connecting to the low-tension wires, or with transformers on the roof of each car, with the carriers connecting to the high-tension car. The low tension on the motors makes the matter of insulation of the motor very easy. Switches are done away with entirely by the use of a choking coil on the secondary motor circuit. When alternate current motors become commercially successful, a method of working of this kind will probably be most useful and practical.

Cupidoscope.—An amusing electrical novelty is brought out by Messrs. J. and C. B. Gibson, 46, Cockburn-street, Edinburgh, for diversion at evening parties and bazaars, and its use will tend at once to break down that initial restraint so often felt at these assemblies. The cupidoscope is a small box containing bell and battery, and a number of lids and pointers. Gentlemen and ladies range themselves in two rows. The first gentleman takes charge of the instrument, and calls upon No. 1 lady to open the lid of the cupidoscope numbered one, and to set the pointer to the number of the gentleman she fancies, afterwards closing the lid, so that her choice is only known to herself, and so on through the whole company. The pushes are then pressed to see who have chosen mutually. After this has been seen, the handle at the end is pressed back, which sets all the pointers to zero ready for use again, so that no choice, unless reciprocated, is known to the company. Hearty amusement will result, and perhaps, even—who knows?—lead to "electric matches."

Patent Decision.—A decision has been given by the Supreme Court of the United States in the case of the Bate Refrigerating Company against Hammond, which is felt to be of considerable importance, but the actual bearing of which seems still to be in considerable doubt. The American patent is granted on condition that it is in force only so long as a foreign patent is in force. The Supreme Court does not, it appears, as, indeed, some papers have made out, overthrow this, but reaffirms it; but in contravention of the opinion of the lower court, it holds that the Canadian patent (which is for five years, but can be extended to fifteen), by reason of its being extended, has never actually expired. This decision will revivify some of the early electrical patents, amongst which are some of Edison's early patents, and, it is thought, strengthen their position; but it is not so sure that other and earlier patents will not also be revivified, and we hear it stated that a patent of Dr Woodward's, of August, 1874, clearly describing a carbon in an exhausted glass receiver, and setting forth, with illustrations, the subdivision in parallel of the incandescent circuit, will remain in force by this decision. The importance of this patent, it is said, has been felt by financiers in America, and very large sums are said to have been offered for the rights of this patent, which may prove to be valuable. We must evidently wait, to see the effect of the decision on the American companies.

Electric Light Buoys.—Atlantic liners have had sometimes to wait for six hours at New York, after straining their utmost for quick passage across, because of the difficulty of entering the channel at night. To facilitate the piloting of steamers, New York Harbour is now lighted by electric light buoys, fitted with incandescent lamps of 100 c.p., which are fed by a current generated on shore and conveyed by cables laid under the sea. The work has been carried out under the direction of Lieut.-Commander Mackenzie and First Lieut. Millis, of the United States Navy, for the Lighthouse Board. The lights are coloured white and red, and mark the deep channel. They are fitted with strong protecting glasses and iron ribs, mounted on the top of long wood spars, 45ft. long, and shackled at the bottom to a cast-iron sinker weighing two tons. The lamps project some distance out of the water. The whole of the top, containing lamp and connections likely to get out of repair, is removable bodily. The cables employed are 32,000ft. of three-conductor cable used as mains, and 15,000ft. of double conductor used at the buoys. The station is situated at Sandy Hook, and is admirably arranged with boilers, engines, and dynamos, all duplicated. Special precautions have been taken to secure good insulation and facility of testing, and altogether the system is well worthy of imitation. Details of the fittings are shown in the *Electrical World* for Feb. 2.

The Submarine Electric Torpedo Ship.—The preparation of the submarine torpedo vessel "Peral," says the Madrid correspondent of the *Daily News*, will be complete on February 20, when the official experiments will be made, including the blowing up of an old wooden corvette in the Bay of Cadiz. Lieutenant Peral is so confident of the success of his invention that he has prepared plans and estimates for building in the Spanish dockyards forty larger submarine torpedo vessels of 130 tons each, at a total cost of twelve millions of pesetas for the whole squadron, and half a million of pesetas for establishing 10 stations on the coasts of Spain and Morocco, where these vessels would get the electrical accumulators replenished. Lieut. Peral says 600 men and 160 officers would be required to man his submarine vessels, which would always be kept ready for war, with electricity stored on board. The crews would be exercised four times each year in torpedo manœuvres. One year would suffice to get the squadron built, and electrical stations fitted up at Barcelona, Mahon, Valencia, Carthagena, Passages, Bilbao, Vigo, Ferrol, Cadiz, and Ceuta, the latter two stations being selected because Lieut. Peral thinks Spanish interests and aspirations require powerful means for action in the Straits of Gibraltar. He declares that the new submarine vessels can be used not only for the defence of the coasts, but might be taken out in tow for offensive purposes by larger war vessels, on condition that the latter carried machinery and means to replenish the reserves of electricity indispensable for navigating and maintaining the fighting powers of the submarine craft.

The British Association.—Since it was decided by the members of the British Association for the Advancement of Science to hold their annual gathering in Newcastle this year, says the *Newcastle Chronicle*, the local secretaries have been most indefatigable in carrying out the necessary arrangements. They have attended to their duties at the offices, in the Literary and Philosophical Institute, most zealously, under the direction of the hon. secretary (Prof. J. H. Merivale). Nothing also will be wanted on the part of leading gentlemen of the dis-

Digitized by Google

trict to ensure the great objects in view, a cordial welcome to the distinguished visitors and highly successful and instructive meetings. According to present arrangements, a large number of halls will be engaged. On Wednesday evening, the 11th September, the practical business of the association will begin by the delivery of the president's address. Then from the following day until the 18th the members will devote themselves to the reading of papers and discussions on the same. On the evening following the delivery of the president's address, and also on the 16th, a lecture will be delivered, and on Saturday night a lecture, it is expected, will be given for the benefit of the working classes generally. On one of the evenings a soiree will be held, whilst during the whole of Thursday, the 19th, the members will visit various places of interest in the locality. So favourable was the impression made of the visits to Tyneside in 1838 and 1863 that it is morally certain the visit of the association to Tyneside this year will rank amongst the most successful of the meetings of recent years, and will be as profitable to all concerned as any of its predecessors.

Electrical Coast Communication.—We are glad to hear that an important arrangement is about to be carried out which promises to be of great benefit to fishermen and shipowners. The Plymouth Chamber of Commerce recently suggested to Lloyd's society that it should permit its men at the various signal stations to send two telegraphic reports daily to adjacent ports free of charge. Each of Lloyd's signal stations has at present a private wire connecting it with the Post Office telegraph system, paying a royalty to the Post Office for every message despatched. Lloyd's society, after some correspondence, has generously recognised the importance of the question, and the honorary secretary of the Plymouth Chamber has been officially informed that the society will gratuitously perform the service described provided the Government forego their royalty upon such messages. The reports so sent would be exhibited at some conspicuous place in each port, and the Plymouth Chamber has undertaken to arrange for the gratuitous exhibiting of these reports at the various centres. The Chamber is also in communication with the Government departments on the subject, and it is hoped that within the next few days there will be authority for announcing that the Government are also prepared to do their share of this valuable work in the same generous spirit as that displayed by Lloyd's society. The signal stations belonging to Lloyd's at present occupy 22 of the most prominent positions as headlands and islands along our coast. The free connection of these to the ports is an important advance on the marine economy of the nation, and it is to be hoped that the connecting of the coastguard and lifeboat stations and lighthouses with the telegraph system of the country will very shortly follow.

The Submarine Cables.—The English and French Governments, it is stated by the Central News, have failed to arrive at an agreement respecting the purchase of the Anglo-French cables from the Submarine Telegraph Company. At the time when the British Government decided definitely not to renew the concession to the Submarine Telegraph Company it was understood that the two Governments should purchase the cables of that company at a valuation, and it is alleged that a promise was given by the British Treasury to that effect. The French Government, however, is now objecting to the purchase of these cables upon any terms, on the ground that they are too old for satisfactory working, and that it would be preferable to lay new and better cables. Mr. W. L. Jackson, M.P., of the Treasury, and Mr. Patey, of the General Post Office, went to Paris recently, and had prolonged conferences with M. Coulon, Minister of Posts and Telegraphs, on the subject, but without altering the opinion entertained by that gentleman. Since these conferences in Paris M. Coulon has sent engineers from France to inspect and test the submarine plant and cables in conjunction with the English Post Office engineers. A thorough examination was made at Dover, as well as at East Dean, near Eastbourne, and as a result of these investigations, the Central News learns, reports have been forwarded to Paris which are by no means favourable to the purchase of the submarine cables. It is believed that the British Government will yield to the wishes of France in this matter, and that entirely new cables will be constructed for working between the two countries. It is somewhat significant, too, that although an agreement has been signed by Belgium and England for working the Anglo-Belgium cables, these have not yet been bought, nor has the British Treasury made any offer for them. It is probable that if new cables are laid between England and France, they will also be laid between England and Belgium. This new development of affairs is a hardship upon the Submarine Company, but it is difficult to see how, in face of the determined opposition of France, the cables of that company can be purchased by England.

Electric Census Taker.—Statisticians may be interested to learn that an electric tabulating system has been invented by Mr. Herman Hollerith, of Washington, to sort the returns of the census cards, or other statistics embodying groups of facts or figures. This apparatus is fully described and illustrated in the New York *Electrical Review* of January 26. Relays are used to control the circuits of the receiving boxes of the cards. When, for example, a card punched for "native, white and male," is placed in the press, the corresponding relays are actuated, thus forming a secondary circuit through the magnet native-white-male, thus operating the corresponding counter or sorting box. In this manner any desirable or possible combinations of the data recorded on the cards may be tabulated. For the more complicated combinations special relays, with multiple contact points, are constructed. It will generally be found that a scheme can be arranged which will bring the most complicated tabulation into a comparatively simple mechanical arrangement. If, for example, there are 10 facts, each of which should be tabulated in combination with 10 other facts, there will be 100 combinations which would require that number of counters. However, as this work is entirely mechanical, such checks can readily be arranged as to secure absolute accuracy in the results. In this note reference has only been made to the population statistics of a census and the army health statistics. This method, however, is directly applicable to many other forms of statistical compilations, among which may be mentioned the statistics of registration of births, deaths, and marriages. Dr. John S. Billings, a well known American authority on statistical matters, says: "It is comparatively simple, not liable to get out of order, and does its work rapidly and accurately. I have watched with great interest the progress in developing and perfecting this machine, because seven years ago I became satisfied that some such system was possible and desirable, and advised Mr. Hollerith, who was

Digitized by Google

then engaged in census work, to take the matter up and devise such a machine as is needed for counting various combinations of large numbers of data, as in census work or in vital statistics. I think that he has succeeded, and that compilers of demographical data will be glad to know of this system."

Halifax.—A letter was read at the Halifax Town Council from Mr. Holroyd Smith in connection with the Anglo-American Brush Electric Light Corporation. The letter, dated January 28th, was as follows: "Dear Sir,—I beg to confirm the verbal proposal made to you respecting establishing the electric light in Halifax—namely, that if the Corporation would be good enough to accord me their undivided support, I am prepared to apply to Parliament for the necessary orders under the Acts of 1882 and 1888, to purchase or lease the land required for a central station and be at the entire cost of the installation, including buildings, engines, dynamos, instruments, overhead distributing wires, transformers or batteries for the houses and shops, with wires, lamps, etc., and to apply the electricity to users by meter at 8d. per unit (which is equivalent to gas at 4s. per 1,000). In order to secure a sufficient number of users to warrant the large outlay necessary for a successful enterprise, it is further asked that the Corporation light the public buildings, such as the town hall, the library, Bank Field, etc., and should the number of glow lamps exceed 1,000 a special liberal discount would be allowed. Further, that the streets be lighted by arc lamps of, say, 2,000 c.p., to be erected and maintained at a rental of £27 per lamp per annum, the number of lamps to be not less than 25, distributed as the Corporation may think fit. If the Corporation favourably entertain my proposal, and a sufficient number of users undertake to adopt the light, I am in a position to commence operations at once.—I am, yours, respectfully, M. Holroyd Smith." A second letter was read from Mr. Holroyd Smith referring to the contemplated enlargement of the gas works, and asking the Council to defer any project of that kind in order that electric lighting might have a fair trial. A proposal was submitted by Messrs. England and Foster, solicitors, on behalf of the inhabitants, saying that over 60 persons had agreed mutually to put down plant and take the light when provided, and immediately the consent of the Corporation has been obtained, it is intended to form a company, called the Halifax Mutual Electric Light and Power Company, Limited, for the purpose of carrying out the system, and an influential board of directors has been already secured. Arrangements, it was stated, have been made with the Schmidt-Douglas Electric Company, Limited, of London, Manchester, and Bradford, for putting down the necessary plant requisite for supplying the electric current. Permission to take overhead wires over various streets would be asked. Letters were also read, asking the Corporation to countenance their rival projects, from Messrs. Blakey, Emmott, and Co., suggesting a preliminary supply from their works until a central station were completed, and from Mr. J. R. Smith. The Mayor suggested the letters had better be referred to a committee, and the following gentlemen were appointed to deal with them: The Mayor, Aldermen Midgley and Pollard, and Messrs. J. W. Davis, J. Bairstow, J. Binns, J. Oddie, W. Utley, and W. Brear.

Southwark Electric Railway.—Some interesting details of the working of the electric railway for the South of London were given at the meeting of the City of London and Southwark Subway Company, held on Tuesday, at Winchester House, Old Broad-street. Mr. C. Grey Mott presided, and referred with satisfaction to the extremely rapid progress which had been made in the construction of the line and works, and stated that they anticipated that the whole of the line would be completed within six or eight weeks, with the exception of a small portion at the Stockwell end. They had obtained a large piece of land at the Stockwell end, where they proposed to concentrate the whole of the engines required in connection with the working of the line, whether for the traction of the carriages, the hydraulic lifts, the lighting of the stations and carriages, the works in connection with the repairing of the engines and carriages, and the general repairing shops. Since the last meeting they had made a very important contract with Messrs. Mather and Platt, of Manchester, for working the line by electric power. The locomotive expenses connected with the ordinary working of an English railway varied from 7½d. to 1s. a mile, according to the special circumstances of the traffic and the nature of the line. The average cost of working a steam locomotive might thus be taken at 9d. a mile, whereas Messrs. Mather and Platt estimated the locomotive expenses on their subway at 3d. a mile, and they had entered into a guarantee for two years that in no circumstances should the cost exceed 3½d. a mile, or they would themselves pay the whole of the excess. On the other hand, the ordinary railway train would carry an average of, say, 250 passengers, whereas trains on their subway would only seat a little over 100. It would therefore require nearly two and a half of their trains to equal the average capacity of one English steam locomotive train, which, however, ran throughout the greater part of the day not one-quarter filled, there being consequently an enormous dead weight, which was earning no return. On their subway they would have very much less dead weight to move. On the Inner Circle Railway a 10 minute service was run, though other trains entered certain of the stations, and thus made the service a more frequent one than 10 minutes but on the subway it was proposed to run a three minute service. The result of that would be that whereas on the Inner Circle there were six trains an hour, on the subway there would be 20 trains in the same time. They ought, therefore, to obtain a traffic larger, proportionately, than that on the Inner Circle, but if they carried anything like that traffic, he believed they would be able to earn such a dividend as would place their shares at a price which would be satisfactory to all the shareholders. Messrs. Mather and Platt had undertaken that their trains should run at a speed equal to 15 miles an hour, including stoppages, whereas he believed that the speed at which the Inner Circle trains ran was 12 miles an hour, including stoppages. The total time occupied in going from King William-street, City, to Stockwell by the subway would be no more than 12 minutes, and to Kennington Oval no more than 10 minutes. Hitherto, as many of them were aware, the journey to the Oval had been long and tedious. They had also arranged with the firm mentioned for lighting the trains, stations, and works by electricity. He hoped the proprietors would consider, in view of what he had stated, that they had a fair and satisfactory prospect before them; and he trusted when they next met that he would be able to announce that the line was open, or else to name the day on which their trains would start running.

SOME PECULIARITIES OF ELECTRO-DEPOSITION.

BY ALEXANDER WATT.

In depositing metals from solutions of their salts by electrolysis, the eye of the experimentalist is often attracted to some unusual condition or form of the deposited metal for which at the moment he is unable to account, and which in some cases even further reflection fails to elucidate. Such phenomena, however, scarcely deserve to be passed by without some attempt being made either to account for them, or at least to bring them to the notice of other observers who may have witnessed similar effects under like or other conditions. In calling attention to a few of the many "peculiarities" of electro-deposition which I have met with in my own practice, I do so more for the purpose of recording the facts than with a view (except in one or two instances, probably) to suggest explanations which, for aught I know, may be beyond the reach of any of us. In order that the peculiarities referred to may be considered individually, I purpose describing them under separate headings, giving the name of the electrolyte in each case from which the result was obtained, as also the conditions under which it was electrolytically treated, and I shall be much pleased if any of the readers of this journal who may have met with similar freaks of electro-deposition should feel disposed to offer such explanations as they think may account for them.

Refusal of Bright Metallic Surfaces to Receive the Deposits.—It is a well-known fact that on highly-polished surfaces of metals the electro-deposited metal can seldom be made to adhere with tenacity, but more especially is this the case with cold solutions. It is true that a mere film of gold or silver may be deposited upon polished brass or german silver which will stand the friction of the moist revolving scratch-brush, but a stouter coating would inevitably "strip" or peel off the underlying metal, unless the brightened surface received a previous scouring with pumice-powder and water, or a coating of mercury by dipping the article to be plated in the ordinary mercurial solution used for such purposes. And this disinclination of metals to adhere to bright metallic surfaces is more particularly noticeable, I believe, when we attempt to coat any given metal with the same metal. Indeed, I have before had occasion to express my firm belief that metals do not adhere well to their kind when deposited by electrolysis, and I am even disposed to think that each time an article is removed from a bath for the purpose of examining it, even for an instant, that the subsequent deposit forms a distinct layer upon the previous film, and not a perfect continuation of the original deposit. In the case of nickel this is often noticeable in a marked degree, and I have known a rod of brass, or "stop" suspended from the negative conducting rod of a nickel bath to be coated with innumerable layers of the metal, each of which curled up and separated from its predecessor, although the rod had never been removed from the liquor. In this case there is little doubt that each time the bath was used from day to day, the new deposit which took place upon the rod formed a separate and distinct layer upon the surface of the metal which had been deposited on it the day before. In connection with this latter view, and the disinclination of metals to deposit upon bright metallic surfaces, the following curious result was obtained some time since when pursuing a course of experiments in the electro-deposition of zinc. In these experiments it was desirable to deposit zinc upon thin sheets of the same metal, for which purpose the purest commercial article was procured. In most instances the plates of sheet zinc, before being used as cathodes, were pickled and scoured, so as to present a clean and slightly rough surface; but on one occasion the plates—which presented the usual bright surface of rolled zinc—were not so carefully prepared as I have indicated, the result being that the deposited zinc only partially covered the cathodes of the same metal, while at the same time the film was absolutely non-adherent, and could be stripped off the zinc plates by simply lifting the metal with the point of a penknife, and then gently pulling it away from the bright surface of the zinc cathodes. On examining the deposit before it was removed, it was found to be riddled with holes, through which the bright sheet zinc was quite visible, while a portion of the stripped metal when held up to the light presented a very peculiar retiform appearance, the metal (zinc) being at the same time perfectly reguline, tough, and chemically pure. Adopting the method which I introduced in former papers "On the Electrolysis of Lead and Tin Salts,"* I determined to treat the porous zinc deposit as a *photographic negative*, and to obtain prints or positive proofs from it in the same way as that adopted in the ordinary processes of photographic printing. To accomplish this, a portion of the deposited metal was laid on the glass plate of an ordinary photographic printing frame. A piece of sensitised albuminised paper was then placed over it, then a few folds of blotting paper, and finally the shutter of the frame was fixed in its place. The glass of the frame was then exposed to strong sunlight for at least an hour, after which the picture, a reproduction of which is shown in Fig. 1, was withdrawn, and subsequently washed and toned in a strong solution of hyposulphite of soda, to which a few drops of chloride of platinum† were added. After remaining about 20 minutes in this toning bath, the print was well washed and dried.

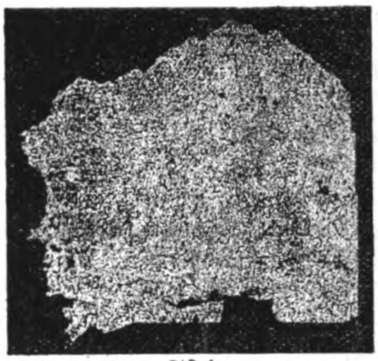

FIG 1

Deposit only on Lower Corners of the Cathode.—When electrolysing a solution of nitrate of lead, consisting of 50 grains of the salt dissolved in 10 ounces of water, with the current of one small Daniell cell, I found that the lower corners of the plate slowly received a deposit of lead, but beyond these limits the metal refused to extend with the current employed. An illustration of the form of the deposit is shown in Fig. 2. When the liquid was diluted, and two cells used, an irregular or patchy film was obtained, the metal only appearing on parts of the cathode, while portions of the deposit were of a non-metallic character.

FIG 2

FIG 3

FIG 4

No Deposit on Lower Corners of the Cathode.—A result of an opposite character to the foregoing was obtained during the electrolysis of a solution of pertartrate of iron—prepared by digesting moist hydrated peroxide of iron in a boiling solution of tartaric acid, the liquid being afterwards diluted. With the current from four Daniells in series no deposit was obtained while the cathode remained stationary, but when it was briskly moved about in the bath deposition of iron gradually took place on all parts of the immersed surface of the cathode except at the lower corners, where there was no deposit, while the upper portion of the deposited metal assumed an irregular or jagged appearance, due to the negative plate having been kept in motion. An illustration of this result is shown in Fig. 3, in which the white surfaces at the lower corners of the plate indicate where the metal was not deposited.

Deposit Commences from the Edges of the Cathode.—When a very weak solution of acetate of lead—50 grains of the salt

* *Electrical Review*.

† Toning with platinum was first suggested by the writer in the *Photographic News*, July, 1859.

Digitized by Google

dissolved in 10 ounces of water and slightly acidified with acetic acid—was electrolysed with the current from two Daniells in series, a deposit of lead at first slowly formed on one edge only of the cathode, but after a short time a corresponding film formed on the opposite edge of the plate, as in Fig. 4, the two films gradually and very slowly extending towards the centre of the cathode, while no deposit whatever occurred either upon the upper or lower surfaces of the plate. After the cathode had been in the bath about 15 minutes from the commencement of the experiment, minute crystals began to form on the surface of the films referred to, from which point the lateral extension of the films appeared to cease, the plate somewhat assuming the appearance shown in Fig. 5. A very similar result was obtained when a solution of basic nitrite of lead was electrolysed with the current from a single Daniell cell.

Deposit only on Upper Part of the Cathode.—On electrolysing a solution of sulphocyanide of lead (prepared by digesting moist carbonate of lead in a hot and strong solution of sulphocyanide of potassium, the solution being afterwards cooled and diluted) with the current from one small Daniell, a deposit of lead slowly formed on the upper part of the cathode—a brass plate—but even after a long immersion no further deposit was obtained. The form of this deposit is shown in Fig. 6. I may state that I have frequently obtained metallic films of this character when electrolysing weak solutions (benzoate of peroxide of iron, for example) with a feeble current. When three cells in series were employed with the preceding solution, the cathode became at once coated all over.

Crescent-shaped Deposits.—Results of this character, as in the foregoing case, usually occur with solutions poor in metal, when worked with a feeble current. I have also

FIG 5

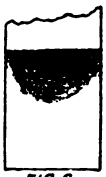

FIG 6

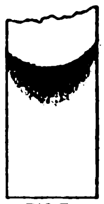

FIG 7

obtained similar results when endeavouring to reduce aluminium from solutions of its salts, both with weak and very strong currents; but in these cases it was not aluminium, but traces of iron and other foreign metals with which the aluminium salts were impregnated, that became reduced by the current. When treating aluminium salts, but more especially *acid* salts, with currents of varying density, I have very frequently found a deposit to take place only at the upper surface of the cathode—not as shown in Fig. 6, but of a crescent form, as illustrated in the accompanying engraving (Fig. 7). These deposits, however, were, as I have stated, due to metallic impurities contained in the aluminium salts used, and were in no degree due to the aluminium itself. In some instances the same form of deposit will take place whether the cathode is allowed to remain stationary or is briskly agitated in the bath, but more generally under the latter condition.

Deposit only on Lower Part of Cathode.—When electrolysing a weak solution of persulphate of iron (prepared by adding three fluid drachms of the concentrated solution to about 10 ounces of water) with the current from three Daniells, I found that the deposit, which commenced at the bottom and lower edges of the cathode, slowly proceeded upward for a short time, after which no further deposit could be obtained upon the upper surface of the negative plate. An example of this is shown in Fig. 8. I may state that many results of a similar character and form have been obtained from other iron salts, and also from solutions of other metals. In the illustration it will be noticed that the upper portion of the film forms an arch-like curve.

Upper Portion of Deposit an Inverted Arch.—In the foregoing example, we have noticed that the upper part of the deposit was curved like an arch; in the illustration Fig. 9, the curve is in precisely the opposite direction, forming, as it were, an inverted arch. This result was obtained during the electrolysis of a very weak solution, composed of persulphate of iron and sulphate of soda, with the current from three small Daniells. In this case the deposit started at the bottom of the cathode, gradually spreading upward, when the film assumed the form indicated in the woodcut, no deposit whatever taking place beyond the outline shown.

Deposit only on Back of the Cathode.—When electrolysing a solution of potassio-tartrate of cobalt with the current from two Daniell cells, a very slight trace only of metal appeared on the surface of the cathode—a brass plate—facing the positive electrode. On examining the back of the plate, however, I was surprised to find that it was coated all over with cobalt. Thinking that possibly I had

FIG 8

FIG 9

FIG 10

inadvertently turned the plate when first examining it, I repeated the experiment with a newly-prepared plate, when I found that a precisely similar result was obtained, namely, that the metal deposited uniformly on the surface of the cathode farthest from the anode—that is, the back of the plate—while the front of the plate had scarcely a trace of metal upon it. The same experiment was repeated two days after with exactly the same result.

Partial Metallic Deposit on Lower Part of Plate only.—A solution of sulphocyanide of cobalt was electrolysed with the current from three Daniells, and a deposit of cobalt slowly formed on the lower edges of the plate to the extent of about half an inch, when a dark brown non-metallic film was deposited in continuation of the metallic film, this having a graduated depth of colour, the darkest portion being nearest the upper part of the plate.

Zigzag Deposits of Copper.—A solution of borate of copper in acetic acid was diluted and electrolysed with the current from a single Daniell. A steel plate was used as a cathode, and this was kept briskly in motion in the bath for about a minute. When withdrawn from the solution, it was found that the deposited metal assumed a very peculiar zigzag form as represented in Fig. 10, while the deposit on the back of the plate, the form of which is shown in Fig. 11, presented a very similar character. The deposited copper was dull, with the exception of a narrow band beyond the margin of the film, which was exceedingly bright. This latter fringe of the deposit is shown by the white outlines beyond the darker shading of the illustrations. The dotted lines above the white outlines referred to show where a slight film of copper appeared at the spots indicated.

FIG 11

FIG 12

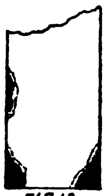

FIG 13

Deposit of a Horseshoe Form.—This peculiar result was obtained under the following conditions: A portion of the foregoing solution was again diluted with water with a view to ascertain whether any further freaks of deposition would present themselves. A clean steel plate was then immersed in the bath, the same current being used, and kept gently in motion. On removing the plate the deposit was now found to have assumed the form shown in the accompanying illustration (Fig. 12), from which it will be seen that the deposit, which was thicker at those parts indicated by the darker shading of the woodcut, assumed a form somewhat resembling a horseshoe, while the remaining portions of the plate were entirely free from any deposit whatever. It was next determined to see if a stronger current would make any, and what, diffe-

Digitized by Google

rence in the form of the deposit, for which purpose two Daniells in series were used, when the succeeding deposit was observed to take place in detached patches, as indicated in Fig. 13, the same character of film being discovered on both sides of the plate. It should be mentioned that the latter result was obtained when the cathode was allowed to remain stationary in the bath for about a minute. As in the preceding results, the patches of deposited metal were fringed with a perfectly bright band of copper, the remainder of the deposit being comparatively dull.

In conclusion, I may state that besides the peculiarities of electro-deposition to which I have had the pleasure to call attention, I have observed many others, which may possibly form the subject of a future paper.

ELECTRIC LOCOMOTIVE FOR MINES.

The application of electricity as a motive power in mines is not a new departure. Some years ago Messrs. Siemens and Halske constructed an electric locomotive for the Zankerode mine, the current being supplied by conductors supported from the roof of the gallery, and other installations on the conductor system soon followed. Mr. Reckenzaun was, we believe, the first to use storage batteries as the source of power, and a locomotive designed by him for the Trafalgar Colliery has been described and illustrated in our issue of June 25, 1886. The latest example of electric haulage in mines is also a locomotive carrying its own store of power in the shape of accumulators, and this has been briefly referred to in our review of last year's progress in electrical engineering. By the courtesy of Messrs. Immisch and Co., the makers, we are now in a position to place some details of this locomotive before our readers. It was built for the Wharncliffe Silkstone Colliery to run on a 1ft. 9in. gauge, and in a drift 4ft. high by 4ft. 6in. wide, whilst its total weight in working order was not to exceed $2\frac{1}{2}$ tons. Before entering upon a description of this locomotive, we may give the results of some trials which were made with it on a surface line at the colliery by Mr. E. B. Walker, and communicated to the Midland Institute of Mining, Civil, and Mechanical Engineers in December last. The line contained a short piece of level; 200 yards of 1 in 70; 150 yards of 1 in 40; 250 yards of 1 in 25; and 200 yards of 1 in 40. On the gradient of 1 in 70 the locomotive would just move a train of twenty loaded corves, weighing together 11 tons, and with fifteen corves, representing $8\frac{1}{2}$ tons, a speed of three miles an hour was obtained, the current being 45 amperes at 100 volts pressure. On the gradient of 1 in 40 the maximum load was eight corves, and on 1 in 25 it was six corves, the speed being a little over two miles an hour. On the level the locomotive could draw thirty corves, the current being 45 amperes.

The frame of the locomotive is supported on springs on axle-boxes outside the wheels, and in order to secure a maximum degree of steadiness, four sets of storage cells have been suspended in front and rear of the wheels from the platform. The wheels are coupled by rods to fully utilise the weight for adhesion. We give herewith a plan and elevation of this locomotive.

The storage battery consists of forty-four modified Tatham cells, each box being 10in. by $6\frac{1}{2}$in. by 11in. high. The boxes are lead lined, and arranged in sections of three in wooden trays. Each box contains nineteen plates, 7in. by $4\frac{1}{4}$in. by $\frac{7}{32}$in. thick, and has a capacity of 150 ampere-hours, the weight being 53lb. The rate of discharge varies between 25 and 50 amperes, and at starting rises occasionally to 65 amperes. Taking 40 amperes as the average rate, the weight of these cells per horse-power works out to nearly 500lb.; and per horse-power hour storage capacity to 134lb. We are informed by Messrs. Immisch that they are now engaged in working out several improvements by which the storage capacity, as compared to weight, will be increased. The motor, which is placed underneath the platform and between the wheels, is of the ordinary Immisch type. The armature is 10in. diameter, and wound with No. 12 S.W.G. wire. There are 480 wires counted around the periphery, and the commutator has 48 sections. The resistance of the armature is ·23 ohm. The field is of the double horseshoe type, and wound with No. 9 S.W.G. wire in two parallels, there being 560 effective turns. The resistance is ·14 ohm, or total resistance of the motor ·37 ohm. The normal current is 45 amperes, and the speed 1,000 revolutions per minute, with a terminal pressure of 100 volts. The weight of the motor is 4cwt., and it gives 4 h.p. at 800 revolutions per minute. On the armature

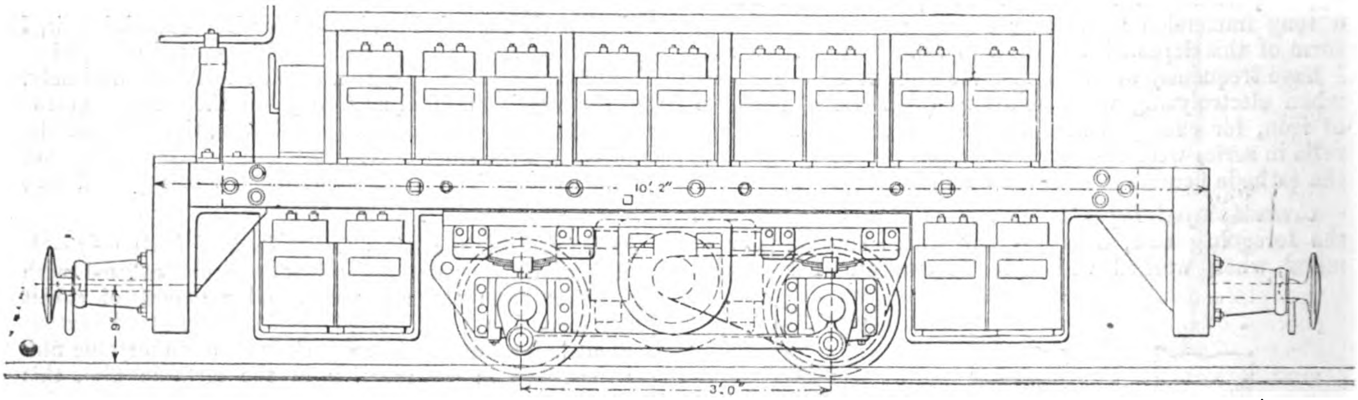

Fig. 1

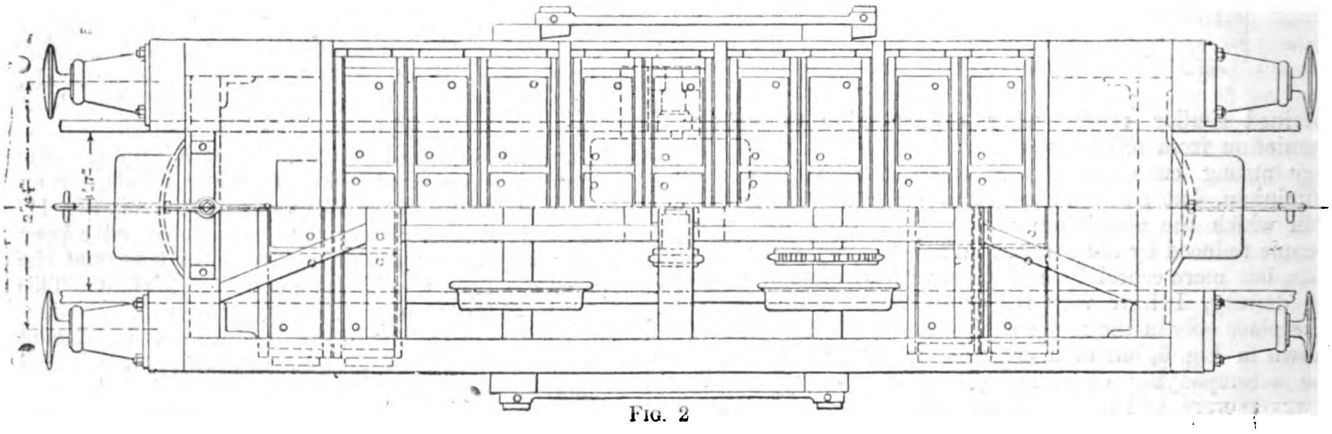

Fig. 2

Digitized by Google

spindle is a small phosphor-bronze pinion; this gears into four steel pinions, placed in the same plane, and 90deg. distant from each other. These pinions are bushed with gunmetal, and run on steel pins carried on a cast-iron disc. The disc revolves on a journal turned outside of the end of the motor bearing. Outside of, but in the same plane as these pinions, is fixed an annular casting of gunmetal, with teeth cut on the inside. The steel pinions gear into the ring, which forms a fulcrum on which they revolve when the motor spindle turns. The power is transmitted from the cast-iron disc by a sprocket pinion keyed to it on the inside next the motor, and a steel chain connects this sprocket pinion to a suitable wheel mounted on one of the axles, whilst the other axle is connected with this by the coupling rods already mentioned. The direction of motion is reversed by a switch, which reverses the magnetisation of the field, and the speed is regulated by iron resistance coils. A brake is also provided. The current for charging the battery is furnished by an Immisch dynamo, which is driven by belt from a Willans engine.—*Industries.*

SUGGESTIONS FOR ELECTRIC TRACTION.

At the meeting of the Ohio State Tramway Association (as reported by the *Street Railway Journal*), a paper was read by Mr. A. G. Clark, not as an electrical expert, but as a layman, giving practical suggestions from his own experience, extending from the establishment of the Baltimore road in 1884. After testifying to his belief in overhead rather than underground systems, as the only ones practically successful on a large scale in America, Mr. Clark continues: In the first place, do not try cheap and inadequate construction; there is no place where economy can be so misapplied, for electrical machinery cheaply and poorly constructed is a most constant source of annoyance and expense. Second, start out with the knowledge that you will duplicate every part of your construction, both steam and electrical, as the most perfect of mechanism may fail, and nothing is more annoying to the travelling public than delay; in addition to this you are repaid in the economy of operation and the saving of your machinery, as the non-crowding of boilers saves coal and the changing off of machinery gives it a rest, which is most desirable, especially to the electrical part, giving it a chance to cool, and saving many a burn out. Third, cleanliness is essential to satisfactory operation; the motor drivers should be required to keep their motors free from oil and dust, and everything that tends to this end should be provided for them. A pit should be conveniently located so that frequent inspection may be made of the gearing. All electric roads should have extra cars, not only in case of accident, but that in rotation the motors may be inspected and taken apart and cleaned of oil and of any copper dust from the wearing of the brushes. The leaning of electric railroad constructors seem to be all towards placing the motors under the cars and making connection by cog-wheels to the axles; in view of this I have some hesitation in saying that my preference, except in case of heavy grades, is to have the motor in front part of car, for the following reasons: First, it gives a better opportunity for the men to keep them clean. Second, being always in sight, any tendency towards electrical difficulty can be checked at once, thereby often saving an armature. Third, my experience has been that the motor drivers become attached to their special motors like a locomotive engineer does to his engine, and take pride in keeping them in order. Fourth, the motor is out of the way of all chance of getting wet or dirty, or magnetically attracting nails or iron material in the streets. Where there are any considerable grades, the more direct method of connection I should consider of advantage. If very heavy grades are to be overcome, a special tow-car would be of benefit rather than have the heavy and expensive equipment on each car to simply meet the requirements of certain grades. Before beginning to build a power-house great study should be given to the planning of the machinery in the building, for if this is done properly a large saving can be made in expense of working. I believe an observance of the points I have so crudely made—as they are regarded or not—will tend very decidedly to make or mar the success of an electric road.

CORRESPONDENCE.

DOES INVENTING PAY?

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Mr. S. F. Walker's letter on this subject is extremely interesting, but does not, to my thinking, give an entirely correct view of the matter.

Your correspondent is undoubtedly right in his view of the great difficulties which beset the path of him who wishes to devise and put into the market any apparatus or method which is to displace existing ones. Not only is it difficult to produce something that shall be really good and new, but the inventor has also to reckon with the fact that he wants to displace that which represents an investment already made in favour of that which calls for fresh expenditure.

Nevertheless I think Mr. Walker goes too far in advising inventors "to don't." The difficulty, to my thinking, is rather that the majority of inventors go outside their own branch.

As a patent agent, I have frequent opportunity to marvel why cabinet-makers will invent pumps, and bootmakers organs, whilst electricians will put all their energies into chemistry, and so on. It is but natural that then things are put forth that have been tried and abandoned dozens of times. If, however, a man keeps to that which is his daily occupation, he knows the actual working conditions, knows of his own knowledge what is feasible, and will, moreover, more readily find credence when negotiating with capitalists.

This brings me to another matter. Inventors frequently ask their patent agent to find them a purchaser. If the attempt is made, the inventor has as often, woefully often, an entirely Quixotic idea of the commercial value of his improvement. He fails to take into consideration the risks to be run by the capitalist, and asks for terms that must appear ridiculous to any cool-headed man.

If therefore I may advise those who are ingenious enough to make inventions I would say to them:

1. Avoid going outside your own branch.
2. Do not spend more, either in time or in money, upon inventing than you can spare for a luxury. Stick to your regular business, and let inventing not become more than a recreation out of which possibly some good may come.
3. Don't be greedy when you have hit upon something good.—Yours, etc.,

BERNHARD DUKES, Patent Agent

226, High Holborn, London, February 9, 1889.

THE DISCUSSION ON ELECTRIC METERS AT THE SOCIETY OF ARTS.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Mr. Crompton is reported to have said in this discussion that our meter has been working at Liverpool "for some weeks." While thanking Mr. Crompton for calling attention to our instruments, we should be glad to be allowed to state that they have been in use there for about a year, and now number about a hundred, and that the engineers, Messrs. Holmes and Vaudrey, are still ordering them from us.—Yours, etc.,

CHAMBERLAIN AND HOOKHAM, LIMITED.

4, New Bartholomew-street, Birmingham.

The Leber Incandescent Lamp.—Efforts are being made among capitalists of Philadelphia to form a company to push the Leber combination incandescent lamp. This lamp, by an arrangement of carbons and switches, is made to emit light at various candle-powers. The 8-16-32 c.p. lamp is the favourite at present.

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months.
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places	4s. 10d.	...	9s. 8d.	...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of Mr. E. Graves, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. Wollaston, M.D., F.R.S., *and* Sir Humphry Davy, F.R.S. *The portraits of* Prof. D. E. Hughes, F.R.S., *and of* Dr. J. Hopkinson, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

ELECTRICAL PROGRESS.

Major Flood Page has done well to direct the attention of readers of the *Times* to the progress of the electrical industries in a letter which we reprint elsewhere. No doubt those who are intimately acquainted with the inner working of an industry are too often occupied with trade concerns to take a general view of the subject. Hence there is no harm in periodically taking them out of the strife and placing them upon an external Mount Pisgah, from whence, as outsiders, they can calmly view the promised land. Their daily routine consists principally in fighting against keen competitors to get orders; they know what orders they have obtained and what they have lost, but these do not make up the industry. No single firm has a chance to estimate for every piece of work, and so the compendious view comes, as we say, from external rather than internal sources. Major Flood Page happens to be in a better position than most people to estimate the progress of electric lighting, so far indeed as it applies to incandescent lighting, for he stands, as it were, in the principal centre for the supply of incandescent lamps, and this supply is a good criterion of progress made. The comparisons he makes relating to the early years of gas and electricity afford curious matter for consideration, and will probably come somewhat in the shape of a surprise to most people. That it should have taken forty years for the gas industry to employ £6,602,010, while the existing electrical companies, inaugurated in about one-tenth of that time, have a capital of over £4,000,000, shows that, owing to the better general education of the people, it now takes less time and trouble to overcome the inertia of conservatism and indisposition to change than it did when gas was introduced. We take it that it is this better education that induces men to come to a conclusion and action sooner than otherwise would be the case. Although men put "cost" in the forefront of the battle, depend upon it they do not forget the incidental advantages which electric lighting, traction, and transmission of power bring in their train. It is a matter of business to growl at a penny and howl at a sixpence, but the blessing of a purer atmosphere, less risk from fire or from explosion, less destruction to decoration, to articles of vertu, is fully appreciated. In assisting to the conclusion to support the industry, as Major Flood Page assures us the world has done, the technical Press may claim a high position. No doubt errors have been committed, but seldom wilfully. Ignorance and inexperience, when put into a position to do evil, have been incontinently handled and corrected before their misdeeds could do much harm, and on the whole the world has been well advised by those whose duty it is to give unbiassed advice. We may deplore that in England we have no such farseeing,

Digitized by Google

energetic capitalists as Westinghouse, but it must never for a moment be forgotten that England does not present so good a field for the work as America. If the electric lighting field had been as good, we fancy the capitalist would have been forthcoming. Still, we are surprised that no English capitalist or syndicate has grasped the possibilities of "power supply." Look at that how you may, estimate upon what figures you please, the promised return is far and away greater than for the distribution of light. True, power stations are not required so universally as light stations, but in the teeming centres of manufacturing populations there is every inducement to install such centres, and every prospect of satisfactory results.

There is one phase of the question touched by Major Flood Page that demands remark. Gas pays good dividends, will electricity prove as bountiful? The time for continued big dividends is past. There are still speculations by which fortunes can rapidly be made, or as rapidly lost. The electrical industry is not one of them. That it should pay fairly well is certain, and if it does not, the fault is to be found among the wirepullers and City men, not from anything arising in the industry itself. If, in the early days, company-mongers loaded companies with capital producing no revenue, that is the fault of the company-mongers—not the business. The latter may satisfactorily employ a capital of £100, and give for it a good return; while if the capital be nominally £1,000, of which £900 has gone into the pockets of promoters, the return cannot be proportionate to the capital. There is a damning indictment some day to be written against the promoters of electrical companies, and it is to their insatiable greed that many companies have failed altogether, and others are still in the non-dividend paying stage. A company starting with a fair capital, using the whole of it productively, should not only command a good business, but should pay a good dividend.

The *Times* leader writer ought to recollect a rather vulgar tale about a servant girl, her baby, and her mistress. Her fault ought to be condoned because "it was such a little one"—not the fault, but the baby. The *Times* says, "But London is great, and central stations are frequently small." Just so, but, like the baby, they have generally the inherent power of growing larger. Small beginnings must not be despised, even when they consist of central stations. If it were our purpose to put the *Times* right upon scientific questions, there are several in its leader that would call for animadversion. One statement must, however, be corrected, that "a current representing a hundred horse-power will run along a copper rod without giving a sign of its presence." Electricians would really be in a fix if such were the case, but, as we all know, there are plenty of signs of a current. Perhaps the *Times* means that the copper rod presents no change to the uneducated eye or hand; still, a paper of its pretensions should take pains to be correct or leave the subject alone. It is comforting to find such powerful advocates coming more and more into line with those who have for years insisted upon the advisability of constructing a system of subways throughout the main streets of populous towns. A debateable point is raised with regard to overhead wires and stress of weather. The policy we have advocated is for pioneer overhead wires to remain, say, for three years. The danger from stress of weather, such as snowstorms, etc., is less when the wires are newly run than after the course of years, when fastenings have had time to loosen or chafe, when wires have become unused, unowned, and unexamined. If the telephone, telegraph and electric light companies were compelled to take down all unused wires, there would be less chance of trouble.

This brief glance over general questions will show that the enthusiasm of Major Page as concerning the present and the future prospects of the electrical industry is warranted, though there must be no relaxation of effort to push forward at every point where vested interests can be assailed with the hope of success.

THE BATE REFRIGERATING CASE.

BY GEORGE P. BARTON.

On January 21st the United States Supreme Court rendered its decision in the suit of the Bate Refrigerating Company against George H. Hammond and Co. The issues were specially made up for the purpose of obtaining an expression from the court as to the right construction of the statute relating to the limitation of the terms of the United States patents to the terms of prior foreign patents. This section of the statute is as follows:

"Section 4887. No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented in a foreign country, unless the same has been introduced into public use in the United States for more than two years prior to the application. But every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than 17 years."

The decision of the Circuit courts have been that an invention secured in this country by a patent issued after a foreign patent for the same invention becomes public property at the end of the original term of the foreign patent, even though the term of the foreign patent had been extended so as to keep the foreign patent in force, and notwithstanding the application for the United States patent was filed first.

The legal questions involved were considered of such importance to various electric light companies that they were represented by counsel. It was contended on behalf of the Refrigerating Company:

"First. That the words 'first patented or caused to be patented in a foreign country," do not mean 'first patented, or caused to be patented,' before the issuing, or granting, or date of the United States patent, but mean 'first patented, or caused to be patented,' before the date of the application for the United States patent.

"Second. That the declaration of the section, that 'every patent granted for an invention which has been

Digitized by Google

previously patented in a foreign country, shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one at the same time, with the one having the shortest term,' does not mean that the patent so granted shall expire at the same time with the term to which the foreign patent was, in fact, limited at the time the United States patent was granted; but it means that it shall expire when the foreign patent expires, without reference to the limitation of the term of such foreign patent in actual force at the time the United States patent was granted."

The court, by Justice Blatchford, sustained this second proposition, finding it unnecessary to consider the first.

The court, after reviewing various decisions of the Circuit Court, holding the contrary of this proposition, says:

"We are of the opinion that, in the present case, where the Canadian statute, under which the extensions of the Canadian patent were granted, was in force when the United States patent was issued, and also when that patent was applied for, and where, by the Canadian statute, the extension of the patent for Canada was a matter entirely of right, at the option of the patentee, on his payment of a required fee, and where the 15 years' term of the Canadian patent has been continuous and without interruption, the United States patent does not expire before the end of the 15 years' duration of the Canadian patent."

The precise point decided, then, is that prior foreign patents as Canadian, Austro-Hungarian, or Italian short term patents, as for five years, or one year, with right to extensions on payment of taxes, or annuities, will not make void United States patents as long as the prior foreign patents are actually kept in force. This decision, then, is important only in those cases where the prior foreign patents have been actually extended and inferentially in cases where the United States patentee had the right to obtain such extensions in the foreign country.

In the important suit of the Edison Electric Light Company against the United States Electric Lighting Company, decided by Judge Wallace last spring, it was held that Edison's patent No. 263,140, dated August 22, 1882, filed August 9, 1880, was void on account of the Austro-Hungarian patent for the same invention, granted July 21, 1881. It appears, however, that the Austro-Hungarian patent was only kept in force until July 21, 1883. The principal question involved in this Edison suit was thus the first proposition, which the Supreme Court has left untouched.

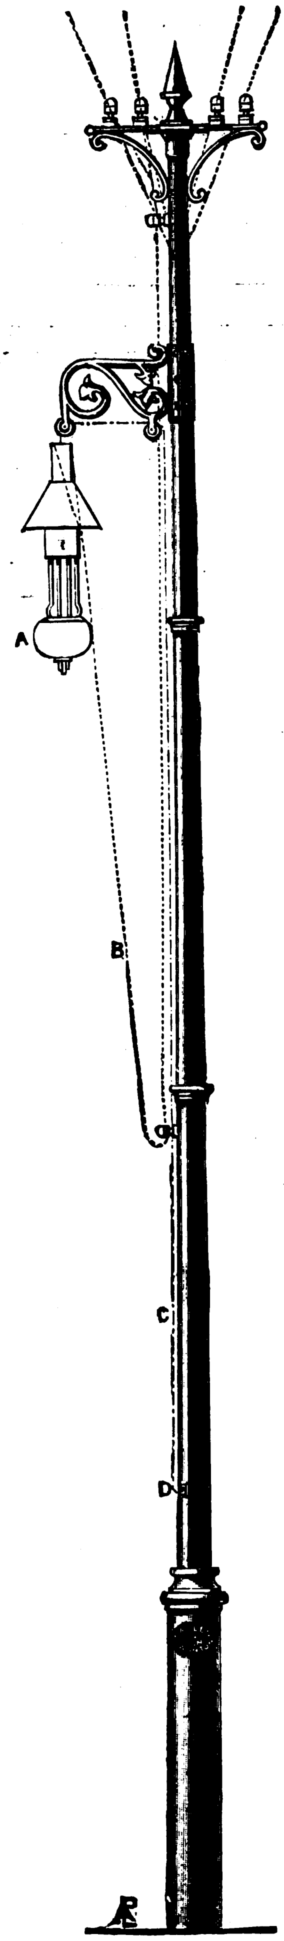
The decision, however, is a victory for the Edison Company in those cases where they have kept their foreign patents alive.

Justice Blatchford, in 1889, speaking for the Supreme Court, reverses Judge Blatchford sitting as circuit judge in 1879, he having held in Reissner *v.* Sharp (16 Blatchford, 383) that the patent involved expired with the first five-year term of the Canadian patent, although the Canadian patent had been extended, and was in force at the time he gave his decision. It will be seen, however, that the most interesting of the two questions presented is still left open.

Justice Blatchford, in the case of Gramme Electrical Company *v.* Arnoux and Hochhausen Electric Company, decided in 1883, held that the date of the filing the application for the United States patent does not in any way relieve the patentee of the statutory limitation, and this is thought to be the correct opinion. The final determination, however, must be left for the Supreme Court, when the precise point raised by the first proposition shall be brought before it.—*Western Electrician.*

STANDARDS FOR ARC LAMPS.

We gave in a recent issue the results of tenders for the standards for the arc lamps to be used in the street lighting at Bath. We now illustrate one of the standards. It will perhaps, however, be convenient to recapitulate the information and the prices quoted for the contract. Tenders were required for about 340 iron electric light standards, 30ft. above ground, with roots varying in depth 3ft., 4ft., 5ft., and 6ft., respectively, with independent flanges, projecting 2ft., to be fixed with wrought



wedges, and delivered free in Bath. The accepted tender was that of Messrs. C. Allen and Son, of Taunton, who quoted £6. 10s. against Messrs. G. Smith and Co., Glas

Digitized by Google

gow, £7. 7s. 6d.; Messrs. Buller Jobson, Dudley, £7. 10s.; Messrs. M. and W. Graybrook, Dudley, £8; Messrs. Easton and Waldegrave, Taunton, £8. 2s. 6d.; Messrs. Jukes, Coulson, Stokes, and Co., London, £8. 2s. 6d.; Messrs. Statter and Co., West Drayton, £12. 7s.

It will be seen that the use of these standards involves overhead wires. The design almost explains itself. There is an independent bracket projecting from the post to allow of the lamp being raised and lowered. The lamps are so suspended, A, that they project about 2ft. from the standards towards the street, and they can be let down to the ground for trimming and hoisted into position. When in position they are locked at the point D. B is the conducting wire, and C the flexible rope for lowering the lamp. Of course, the only objection to this form of standard is to be found in the shadows cast. Otherwise it is simple, elegant, and cheap.

ELECTRICAL PIANO MUSIC RECORDER.

In the *Transactions* of the American Institute of Electrical Engineers for January is a description of an electrical apparatus, invented by Mr. Abdank, for the registration and reproduction of the notes of a piano. An apparatus of this kind should be exceedingly useful to composers for reproducing their improvisations, and enquiries have often been made as to the possibility of such an instrument. Mr. Abdank's apparatus comprises two parts—a melograph for recording what is played, and a melotrope for reproducing this music from the record made by the melograph. The melograph consists of a system of contacts fastened under the keyboard; these are connected to an instrument like a Morse recorder, and when the key of the piano is depressed a mark is made on a strip of paper corresponding in position to the note. It not only records the notes by the length of the line, but records the time the note is held. This record, when the piece is finished, is passed through a perforator which perforates a piece of stiff paper with rectangular perforations corresponding to these lines of the record. This is done by means of an electric apparatus which consists of a little square punch, which travels up and down very rapidly, driven by an electric motor. The lines on the paper are first run over with a puncturing pin, then this paper is passed over a series of contacts. Wherever the paper is punctured, connection will be made, which connection will work this little punch at a place corresponding exactly to the place of the line on the record. In other words, this record on stiff paper is an exact counterpart of the other, only that it is perforated with smooth rectangular holes, whereas this is originally merely a written record. This record is then ready for the melotrope—the reproducing apparatus. The melotrope is merely mechanical in its action; but the idea of the inventor was to imitate as nearly as possible the motion of the finger.

In ordinary mechanical piano players, the keys are merely depressed by a force which is constant, and, in short, the whole apparatus is very mechanical in its action; but in this case the inventor has tried to imitate the motion of the finger; in other words, he has tried to depress the keys softly, gently, or with considerable force, to hold them down a longer or shorter time. This is accomplished in the apparatus Mr. Abdank exhibited, by means of a long roller which extends over the length of the keyboard to be played upon. This roller has cut into it a number of grooves, the sides of which are slightly inclined. The instrument exhibited was arranged for three octaves, with 37 notes. There are, therefore, 37 of these grooves. A roller is turned constantly in one direction, and when a string is tightened it pulls down a finger resting on the keys. The tightening of this string is performed by mechanism, consisting of a little wedge which is run into the groove. The little wedge is actuated by levers which run over the paper. Wherever they come opposite to a hole the lever passes through the hole, and in passing through the hole the end of the lever makes a motion which is transmitted to the little wedge. The wedge is pressed into the groove, tightens the spring, and pulls down the hammer, so that wherever there is a hole in the record the corresponding wedge will be pushed into the corresponding groove, which will tighten the string and press down the key, and will hold the key down as long as there is the hole in this paper. The pressure exercised by the finger in playing the piano is sometimes as much as 5lb., so that these little fingers must come down at least with a force of 5lb., and in the melotrope they can come down with even greater force, and the apparatus can play even louder than a person can play. It may be added that the apparatus does not automatically produce *piano* and *fortissimo* effects. Wherever *piano* should be played, and wherever *fortissimo* should be played, it is written on the music, and the effects of *piano* and *fortissimo* are produced by a little lever on the side of the instrument. This little lever does nothing more than run these wedges toward the roller or from it. The force is greater when they are moved towards the roller, and less when they are pulled away. The apparatus can be as well constructed for seven octaves as for three. It is necessary to go over the record by hand and puncture the holes, as the notes not necessary can be left out. Mr. Abdank played the overture to "Carmen" and the "Boulanger March," and afterwards amused his audience by reversing the card and playing it the other way up, which had the effect of giving the chords perfect, but in the minor. Mr. Abdank then played the piece backwards, and also played a piece improvised for the melotrope in his laboratory, and converted it in one hour after he had played it.

VELOCITY OF LIGHT.*

BY SIR WILLIAM THOMSON.

The number of electrostatic units of potential in the electromagnetic unit of potential is essentially a velocity, and experiments have proved it to be so nearly equal to the velocity of light, that from all the direct observations hitherto made we cannot tell whether it is a little greater than, or a little less than, or absolutely equal to, the velocity of light.

Sir W. Thomson is engaged now in making a set of electrometers which will measure by electrostatic force potentials of from 40 volts to 50,000 volts. The standardisation of these instruments, up to 200 or 300 volts, is made exceedingly easy, by aid of his centiampere balance, with a voltaic battery of any kind, primary or secondary, capable of giving a fairly steady current of one-tenth of an ampere through it, and platinoid resistances in series with it. The accuracy of the electromagnetic standardisation, within the range of the direct application of this method, is quite within one-twentieth per cent. A method of multiplication by aid of condensers, which was explained, gives an accuracy quite within one-fifth per cent. for the measurement in volts up to 2,000 or 3,000 volts, and with not much less accuracy, by aid of an intermediary electrometer, up to 10,000 volts. Such a potential as 10,000 volts is convenient for measurement by an electrostatic balance, which was fully explained in the lecture and illustrated by a drawing. But hitherto he has not been able to make sure of the absolute accuracy of this electrostatic balance to closer than one-half per cent. The results of a great number of measurements made in the Physical Laboratory of the University of Glasgow, during the last two months, give the required number, commonly called "v," within one-half per cent. of 300,000 kilometres per second; the velocity of light is known to be within one-fourth per cent. of 300,000 kilometres per second. Results of previous observers for determining "v" had almost absolutely proved for "v" at least as close an agreement with the 300,000 as this. He expressed his obligation to his assistants and students in the Physical Laboratory of Glasgow University, Messrs. Meikle, Shields, Sutherland, and Carver, who worked with the greatest perseverance and accuracy in the laborious and often irksome observations by which he had attempted to determine "v" by the direct electro-

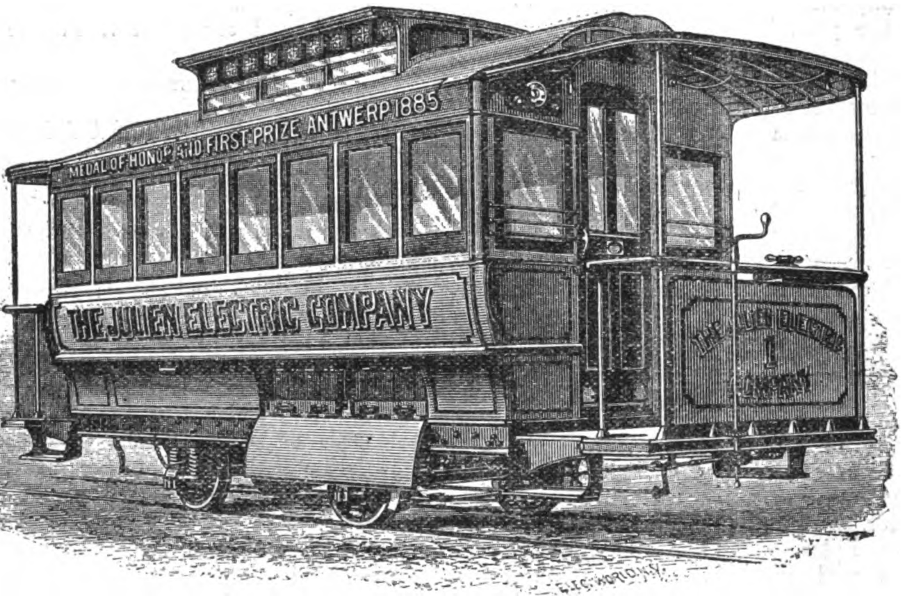
meter method as exactly as, or more exactly than, it has been determined by other observers and other methods.

THE JULIEN TRACTION SYSTEM.

It will be remembered that successful experiments have been recently made in Birmingham under the auspices of Messrs. Elwell-Parker, as constructors of tramcars driven on the Julien system, and therefore, in continuation of our information as to what is going on in this direction in America, we this week give some account of the work of the Julien Company in New York.

There are now eight cars in actual passenger service on Madison-avenue, through the heart of New York, to City Hall or the Post Office. The route is somewhat similar in traffic and the difficulties to be overcome to a trip from Hyde Park to the Bank. It is expected that the number of cars will immediately be increased to 12 in service, with two or more in reserve.

Of the cars now in service, No. 1 has been running since the 17th September, No. 3 since the end of September, and No. 2 for the past six weeks, the remainder more recently. It is remarkable that, although the cars are subjected to the severest tests in the shape of grades of five per cent., curves with a radius as low as 21 per cent., with a rising gradient at that, and passengers to the number of nearly 70 at a time on the car, none of the cars have ever broken down on their journeys, but have always come back to the station without any extraneous assistance. In three or four instances the company have had stoppages arising from the usual mechanical difficulties, but in such instances they have always been enabled to correct the evil in a few minutes, so that the car could proceed on its journey. The chief, and probably now the only remaining difficulty to be removed is that arising from the commutator brushes. One of the greatest, and almost only yet unsolved, problem among electrical engineers has been the proper adjustment of brushes on commutators, to get continuous, uninterrupted, and satisfactory work without excessive sparking, especially under varying loads. This company's only difficulties have arisen from this source. They are gradually overcoming the difficulty, however, and in some of the motors they have recently constructed (where the commutator has wider segments and mica insulation) they have encountered no difficulty whatsoever.



The cars are giving great satisfaction to the public, and have worked so well that a large future sphere of action, especially in large cities, seems to be accepted as a foregone conclusion.

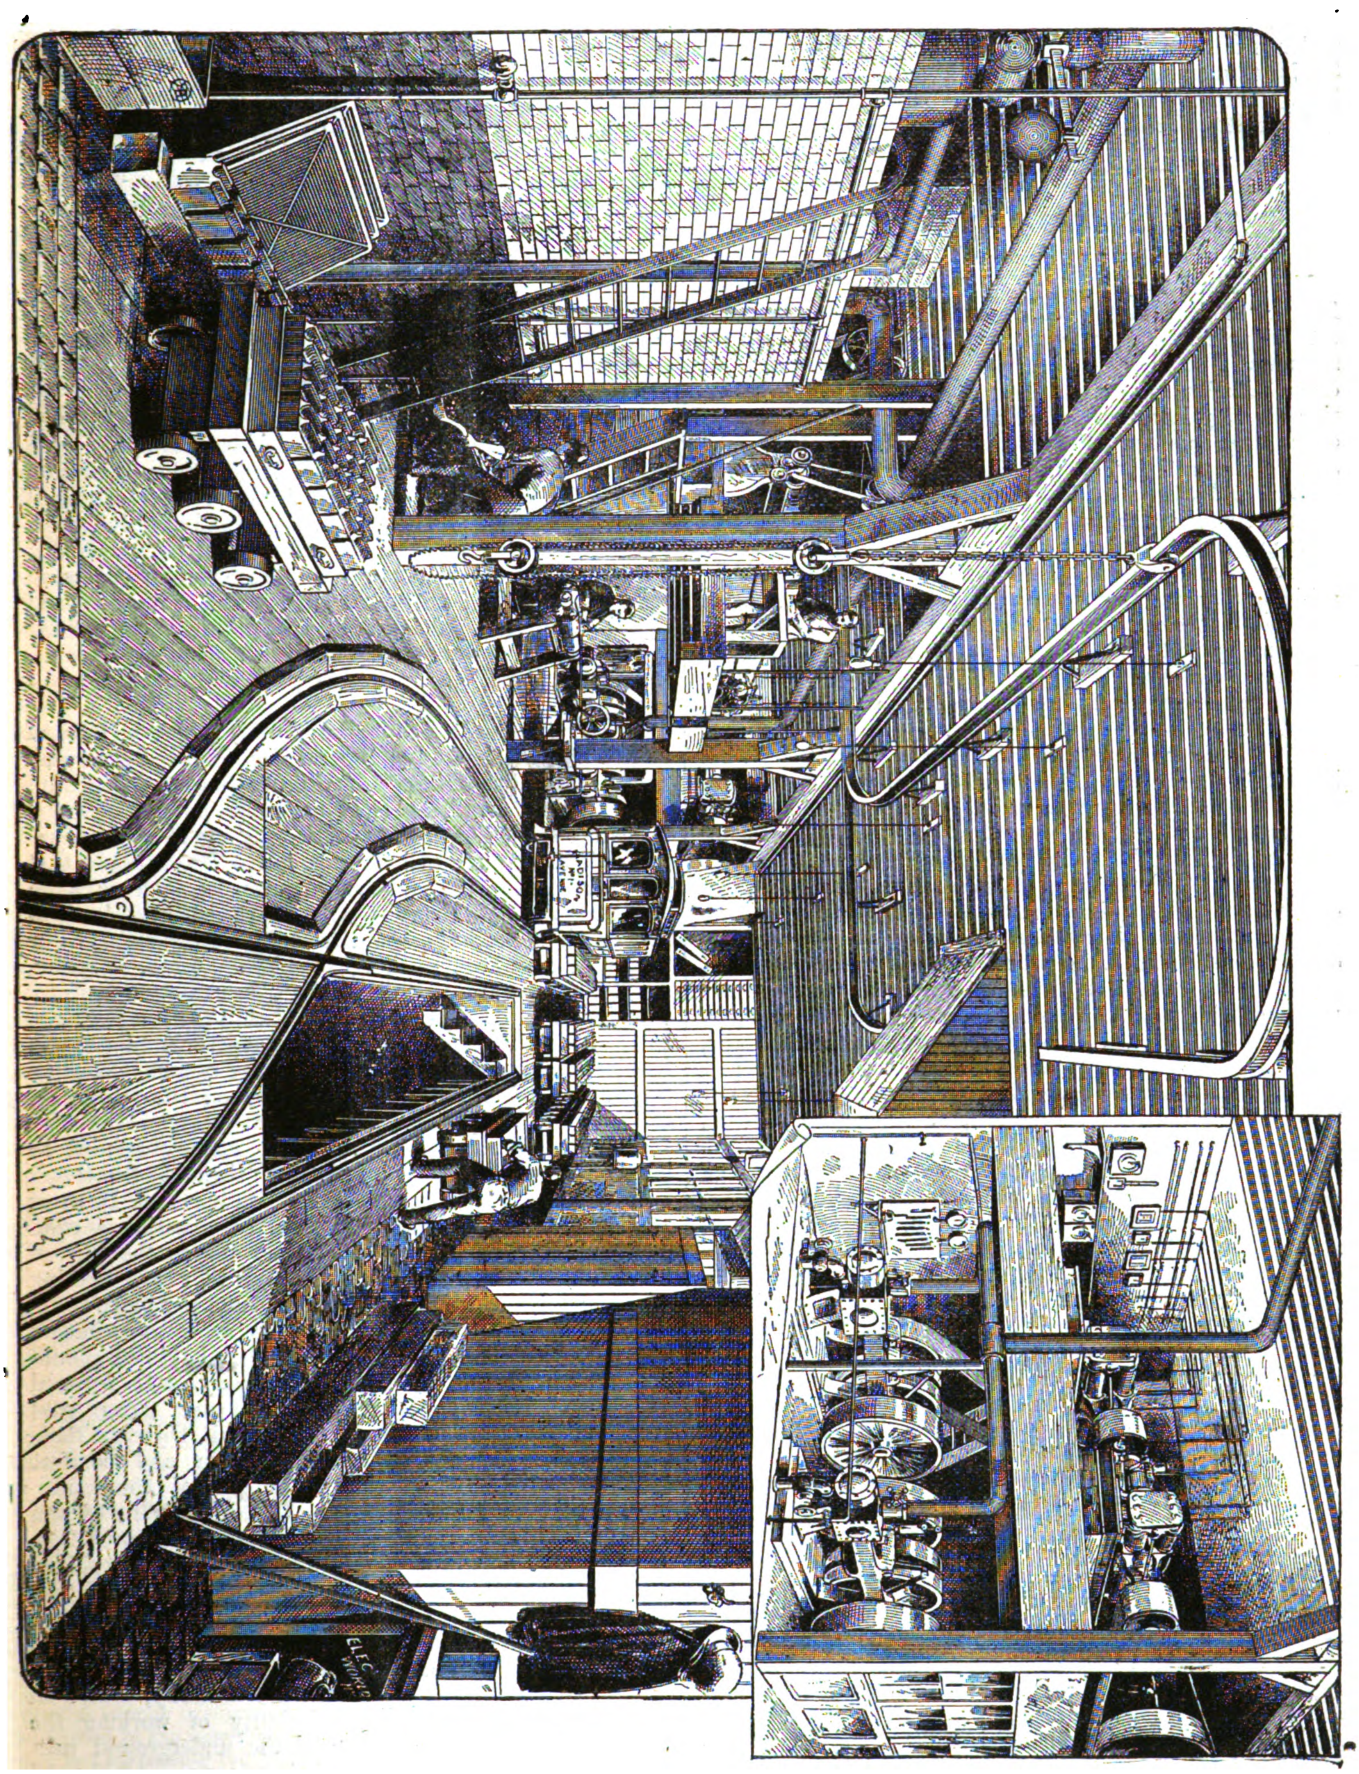
One of the most interesting questions relates to knowing the cost of running a car. Of course the company have not gone far enough yet in their work to be enabled to give any accurate or reliable data as to the cost of maintenance, but they inform us that, so far as the batteries are concerned, the system is an assured success; because the batteries are produced at a price so low as to enable railroads to replace them with economy, even though their economy should be less, much less than that now claimed for them. The Julien Company have now a very large number of installations for lighting, and some of those installations are now approaching nearly two years of service, and while cells and plates have, of course, been replaced, yet the percentage of such replacement has been very small. They state unhesitatingly, less than one-third, and undertake to say that the percentage will be much smaller during the next two years, both because the consumer has learned to take care of the battery, and because a better battery is now made than then. In their street car work no deterioration in the batteries has yet been noticed.

The standard car (18ft. body) carries 144 cells of the type B battery. The cell is a small one, weighing about 32lb. in all, but it has the capacity of at least 300 watts. On an average discharge of 35 amperes, it is seen that the car starts from a station with about 58 electrical h.p. hours capacity. Within the last few days the cars have been making three round trips, or 36 miles, on one charge of battery. It is found that it takes 15 h.p. hours for each round trip. They have not yet attempted a fourth trip, for the cars, being in daily service, have no time to experiment, and there are no instruments to measure the amount of energy remaining in the battery at the end of any trip. The only guide is the voltage, and that is a very uncertain one. The aggregate voltage of the battery at the start is about 320. The fall is found to be very gradual and very slight. At the end of the third trip, or 36 miles, the day previous to the communication made to us on December 7 the voltage of each cell was still above two; there were nearly 300 volts still remaining.

It may interest readers to know that the experience of the Julien Company with their batteries has upset many of the theories read of in books in relation to the abuse of a battery. One battery has been in service on an experimental car about a year and a half, and has recently been on daily passenger service on car No. 3 for four months. As the motors of car 3 are rather inefficient, this battery has been subjected to great abuse. There is not a trip the car makes that the battery is not called upon several times to yield 120 amperes in parallel. A good deal of the active material has been shed by the positive plates, but not one of them has buckled, nor become disintegrated. The battery still has a capacity of about 250 watts for each cell. The plates of this battery were hand-spread, and were made when the company was young at the business. The batteries now made, and which have been in service on the new cars for nearly three months, have so far shed none of the active material—absolutely none. Of course

Digitized by Google

their capacity of 300 watts continues right along. Now that the cars make three round trips on one charge, the battery is changed but once a day—a great saving in time and labour. This change is made by means of a hoist on either side of the car, and of the same length as the car-body. Each hoist is run by a small electric motor. It is provided with two shelves; one to receive the discharged battery when the car comes in, and the other containing the charged battery for service. These batteries stand on shelves at the back of the hoists. Shelves on either side, about 15ft. high, contain enough batteries to run six cars. They are the same width as the hoists. The batteries are set in trays which rest on rollers on the shelves as well as on the hoists. The rollers are worked by means of a wheel at the end of the shelf-rack. By turning this wheel, all the battery is moved on to the hoist at the same moment, and in turn from the hoist into their position on the car. By this device six cars are run from a space 54ft. long, 11ft. wide, and 15ft. high. Those cars would require 125 horses to do the same work, so that a comparison can be made between the space



Digitized by Google

required for that number of horses, and the moving of them about, and that occupied by the batteries. Moreover, the hoist and shelf-racks are quite inexpensive and simple of construction.

The cars after their day's work are taken into the car-house by means of a little shifting electric locomotive, which is called a "shifting engine." It has a small body, 8ft. long, mounted on a small truck of a 4ft. 8½in. wheel base. The body contains 74 cells, grouped in four series, and one 10 h.p. motor.

THE PROGRESS OF ELECTRICITY.

Major Flood Page has written the following letter to the *Times*: "It is a matter of common observation that the use of electricity is spreading, and, owing to the accounts that have appeared in the *Times* on the central station of the London Electric Supply Corporation at Deptford, which is being built for the supply of a large portion of London with the electric light, and to the activity of the Chelsea, Kensington, Metropolitan, and other electric companies who are putting up central stations, the public at last begin to believe that some movement is being made.

"But as there are many who, though interested in the subject, have no opportunity of ascertaining the amount of progress that electricity is making, I trust that you will grant me space to bring together a few facts connected with the increase of electric lighting in England—facts which, thanks to the electrical journals, are known to the electrical world~~, but not~~ to the general public.

"So vast is the metropolis, and so little do we know what is going on in our midst, that, doubtless, it will be a matter of astonishment to many of your readers to be informed that there are actually in operation nine central stations, some small, but others of considerable importance, in London; while 12 other central stations are in progress, more or less advanced, making a total of 21 stations in operation, or in course of construction or organisation, in the county of London. And when we look to the provinces, we find that central stations have been started, and are working, with more or less success, at places as far apart as Brighton, Barnet, Blackpool, Chatham, Eastbourne, Hastings, Leamington, Liverpool, Taunton; and that provisional orders are being sought either by municipalities or by companies in Bath, Bradford, Bournemouth, Cardiff, Derby, Exeter, Edinburgh, Glasgow, Ipswich, Liverpool, Swansea, Sheffield, Waterford, Lynmouth, Folkestone, and Reading; while plans are maturing for central stations in Manchester, Southampton, Okehampton, and other places, among others, the City of London, which it is proposed to divide into three sections, giving a chance of lighting to three separate companies. Some of these may not be carried out, and some may fail; nevertheless they make a goodly array for a beginning.

"We may expect that, during this and the next session of Parliament, we shall see a considerable number of provisional orders for electric lighting granted—the exact number I dare not attempt to predict, but it is safe to say that we may hope to see not less than 50 district central stations working under provisional orders before very long.

"I know no way of measuring the progress that is being made so simple, and at the same time so convincing, as comparing it with the early years of the gas industry. We know, from a return which was made to Parliament in 1847, that between 1810—the year in which the first Gas Act was passed—and 1820, only 20 gas companies received their Acts, and it seems indisputable that electrical central stations far in excess of this number will be at work long before ten years have elapsed from the passing of the Electric Lighting Act.

"It is not possible to arrive at the amount of capital already invested in electric light companies in the United Kingdom, as a very large proportion of the work is being done by private companies; but the limited companies engaged in electric lighting have a nominal capital of more than £4,000,000, of which about half has been called up; while it appears, from the return to Parliament already quoted, that from the year 1810 to the year 1850, 134 gas companies were established, with an aggregate capital of £6,602,010, so that it seems manifest that within 40 years from the date of the first Electric Lighting Act, a very much larger sum will have been invested in connection with electricity than was invested in gas during the 40 years from the passing of the first Gas Act. But some of your readers may say it is all very well to talk about central stations and the progress of electricity; but gas companies cover the kingdom and, in every instance, pay good dividends. Are the electric companies ever going to pay dividends? I hope and believe that a majority of the central stations will be so managed as to pay, and that the allied electrical industries will also pay fair dividends; but we are not exempt from the difficulties which beset new industries any more than the gas companies were 70 years ago.

"The words which Mr. Burdett uses of that great and successful company the Gas Light and Coke Company (the chartered company) of London might, with but little alteration, be used of the electric companies to-day:

"'The early struggles of the chartered company were very great. It had to carry out on a gigantic scale, and on commercial principles, what had hitherto been matter of experiment only, and almost everything had to be invented, calculated, designed, and constructed in order to arrive at a successful issue. For years the rental was little more than nominal; and when, at a later period, it had achieved a position of some public utility, and was realising a fitful profit, the shares were almost always at a heavy discount, and the dividend, when any was paid, seldom exceeded 6 per cent.'

"It is well to bear in mind that in 1820 the price of consols ranged from 65 to 70, and that we no longer speak of the sweet simplicity of 5 per cent., but of the painful simplicity of 'Goschens' at 2¾ per cent.

"But electric lighting is not the only use to which electricity is being put; and there is no reasonable doubt that electricity will be used for motive power as much or more than for lighting. Everybody is aware that in Ireland, at Blackpool, at Brighton, and elsewhere, electric railways or tramways have been working successfully for some years, not to enumerate those which are working successfully outside the United Kingdom; and within the last few days an electric omnibus has been making experimental trips in London, and the owners hope during the summer to place their first batch of these horseless cars on the streets for daily work in competition with the omnibuses.

"We are about, however, to see electricity applied to locomotion on a larger scale in London than has heretofore been tried in England, as Messrs. Mather and Platt, of Manchester, have got the contract for constructing a complete electric railway for working the traffic in the City of London and Southwark Subway, and they are making arrangements for running 2,200 train miles per diem.

"Lord Bury's company are about to make experiments on the Metropolitan Railway, and in, fact, I think I should not exaggerate in saying that we may look forward with good hope to seeing before many years pass over our heads the Metropolitan and District Railways worked by electricity. The gain and comfort to the many millions who make use of these railways would be incalculable. I am not unaware of the difficult and complicated nature of the many problems, scientific and commercial, which will have to be solved before this desirable end is attained. Nevertheless, I venture to think that the scientific difficulties will be more easily overcome than those connected with the expense of making such extensive changes as will be involved in the substitution of electricity for steam. Naturally, wise men express doubt as to the practicability of working the enormous and unequalled traffic of the underground railways by means of electricity, but there are men connected with electrical engineering who are studying the question, and will be prepared to deal with this desirable and suggestive development.

"I have purposely restricted my remarks to the work going on in England, although I can speak from personal observation of the progress which has been, and is being made throughout the length and breadth of Europe. A

Digitized by Google

large portion of Paris has within the last few weeks been parcelled out for lighting by six companies. Central stations are at work in Moscow and St. Petersburg, Berlin, and many towns in Germany, in Vienna, and in numerous towns in all parts of the Continent. The United States maintain their lead, and with characteristic energy keep ahead of all other countries in electrical development.

"Sprague's and other motors are now being used in the United States to an extent that it is difficult for us to realise, and the motor companies are being taxed to their utmost capacity to keep pace with the demand. Germany is not behind, and the town of Metz will serve as an illustration of the practical use to which the military authorities are applying electricity, for electric light is used for lighting the railway stations and the railway approaches, for lighting the ramparts, search lights being used for illuminating the surrounding country. The barracks are electrically lighted, and the Government have portable plant for accompanying troops while skirmishing at night.

"Within the last few months an electrical section of the London Chamber of Commerce has been organised—already there are nearly 100 members of the section—and the discussions which take place are eminently practical and useful. In this we see electricity for the first time taking its place as one of the recognised industries of the country.

"A few weeks ago the Society of Telegraph Engineers, which has done useful scientific electrical work for 17 years past, adopted the new title of the Institution of Electrical Engineers, and Sir William Thomson, F.R.S., the president, speaking at the general meeting of the newly-named institution last month, said that the members and associates numbered 1,550, and, referring to the many branches of electricity with which the institution was occupied, said: 'With all these grand subjects of applied practical science for our province, I think the Institution of Electrical Engineers may feel that it has a great and noble dominion.'

"The Board of Trade, with wise discretion and sound judgment not always to be found in public departments, is giving its earnest and cordial support to all well-considered plans for extending the use of electric light, and if central stations are before long put upon a sound basis, no small credit will be due to the cautious judgment which the officials of the Board of Trade have exercised.

"I think, therefore, that all who are interested in the progress of electricity—and who is not?—may well be hopeful. For my own part, I look forward to a sure and certain development of electricity in all its branches, and think that before long we shall be as familiar with electric lighting and electrical motors, and perhaps phonographs, as we now are with its use in connection with house bells, telephones, and telegraphs."

ELECTRICITY: LIGHT AND POWER.

BY HOLROYD SMITH.

(*Continued from page 79*).

Though there are numerous applications on the continent surpassing what we have in this country, we have to cross to the other side of the Atlantic for public works on a large scale. In New York most of the public streets and squares are lighted by electric arc lamps, and many of the new towns, or cities as they call them, have no gas works; they realise the superiority of electricity, and adopt it. Even the staid, old-fashioned Quaker city of Philadelphia possesses an installation which, of its kind, is unsurpassed. The Girard College, or Orphan Home, the grounds of which cover several acres, have distributed about them tall columns of light ironwork, surmounted with a cluster of five-arc lamps in clear glass globes covered with reflectors. They are so high as not to dazzle the eye by their brilliancy, and powerful enough to illuminate all the grounds and the streets and houses in the neighbourhood, not with a light equal to day-time, but surpassing the best effect of an American full moon.

Perhaps the grandest display of electric light in the world is the torch held aloft in the hand of the Statue of Liberty, presented by the Republic of France to the Republic of America, that has been erected on an island in New York Harbour. It stands there defying the fiercest tempest, flashing a light of welcome to all seeking the shores of the newer and larger world.

The praise given to America needs some qualification, and it is only fair to ask, why has the practical application of electricity there so far outpassed the rest of the world? Though it is largely due to the national characteristic of dash and go-ahead, it is not altogether due to these qualities. An American can "calculate" as well as any man; he is not beaten in this particular even by the Hebrew brotherhood—which is perhaps the reason why so few of the tribe of Judah and Benjamin reside there—and being able to calculate, he finds that, light for light, electricity is cheaper than gas. This applies to America more so than here, first because gas there costs about 12s. a thousand instead of 2s. 6d. as here, and, secondly, because the authorities will permit a rough-and-ready method of erecting poles and running wires that would not and ought not to be countenanced in a civilised country, thus of course cheapening the cost of installation. And further, in England nearly every hamlet has its gas plant, which means so much money sunk; there new towns and districts are springing up every day, and having no capital account to write off there is no hesitation in adopting a new method.

Another feature of the American character may be cited as explanatory of the rapid adoption of electricity in that country—viz., the high cost of labour, and as a result the welcome and encouragement given to men who can devise means of lessening the necessity of employing labour. An inventor in America is looked upon as a valuable man to be encouraged, whilst here the custom is to shun and suppress and hinder as far as possible, the natural result being that our best men are drawn there, where their efforts are appreciated and rewarded.

The American tendency to adopt has resulted in obtaining for them a credit for originality more than they deserve. The public are apt to associate an invention with those who develop and bring it into practical use, so let it be here stated that English scientists owe very little to the Americans, whilst the American practice is mostly built upon English science. Theories formulated and experimentally proved by English electricians have found no remunerative field here. They have been communicated through the press, or otherwise, to the United States of America, understood, realised, put into practice, made a commercial success, large companies formed, then brought over here and sold to speculators of the Stock Exchange, who, not able to understand, did not appreciate the fundamental truth as propounded by the originator.

As an illustration of this may be cited the telephone. No capitalists in the old world would find the necessary money for working out the conception and making it a reality; but American ability, enterprise, and legal skill enabled the facts known to scientists here to be developed and so patented, that a large, and strong, and profitable monopoly has been obtained. Having mentioned the telephone, it will be well to correct a popular misconception respecting it. It is generally supposed that the voice is transmitted from the speaker to the hearer. This is not so. No sound or sound-waves are transmitted as through a speaking-tube. It is not the voice of your friend you hear, it is the imitation of that voice, an imitation so like the original it is difficult to realise that it is only a reproduction.

To understand how a telephone really works, the reader must remember the leading principles given as the A B C in the commencement of this article. There it was stated that, by waving a piece of iron in front of a magnet round which a copper wire was wound, electric energy was made to pulsate through the wire. Now, if the piece of iron is a thin sheet, so thin as to be affected by air pressure, then you have only to talk in front of that iron sheet whilst it is held near to the pole of a magnet, and the bulging and straightening of the thin plate has the same effect upon the magnet as waving the iron—viz., it causes electric pulsations to pass through the wire surrounding it. Now, that wire has only to be wound round another magnet, no matter how far away, and the pulsation of electricity will alter the strength of that magnet, causing it to attract and relieve the sheet of metal in front of it—viz., make it vibrate in the same way that the speaker's voice made the first sheet vibrate, and the vibration of the second plate acting upon the air reproduces the sound.

The order therefore is—the speaker's voice vibrates the plate or "diaphragm" of the transmitting telephone, the vibrating plate causes pulsations in the copper wire; those pulsations passing round the magnet of the receiving telephone, vibrate its diaphragm, which reproduces the sound.

The reproduction is so like the original it would be possible for a listener in Manchester to recognise the voice of the speaker in London.

Some idea of the commercial value of this instrument may be given from the statement that in England over £4,000,000 is invested in telephone exchange companies, and the shares of most of them are at a premium.

Whilst on the subject of popular errors it will be well to mention the gravest—viz., the credulity that has enabled a number of unprincipled men to do a large and profitable business in electric health appliances on the fallacious statement of their curative effects. Too strong a protest cannot be raised against such trash, and readers before investing their money in any advertised wonder-working belts had better ask the opinion of someone uninterested in the sale and with sufficient electrical knowledge to be able to advise. Electricity may be life, but

Digitized by Google

even taking that as a fact, it does not make a piece of red flannel with a few strips of crinoline steel stitched into it a life-saving apparatus.

The scientific papers have of late been very strong on this subject, but unfortunately such papers are seldom read by the general public, who are the victims of this charlantry.

When Anderson, the wizard of the north, was in the height of his popularity, one of the wonders of his exhibition was a little electric carriage that ran to and fro on a table in front of the stage, and he used to prophesy that some day carriages would be run in the public street so propelled. That day has come, and it has fallen to Lancashire, the home of co-operative societies, to have the first successful electric tramway ever made; and the many thousands who yearly visit Blackpool (in addition to the usual numerous attractions of that health-giving place) have now the satisfaction of being taken from end to end of the fine esplanade in commodious tramcars driven by electricity.

No horses, no steam-engines, to the casual observer nothing, but the cars running to and fro propelled by some unseen power, stopping, starting, going quickly or slowly at the driver's will, up hill and down hill, sunshine or shower, full or empty, winter and summer, for the last three years, those cars have run, proving, beyond the possibility of a doubt, that not only can electricity be used, but also that, by the employment of electricity, the work can be done at a cheaper rate than by any other means.

It is only natural to suppose that the reader will hardly be content with a mere statement of facts, but will probably want to know how it is accomplished; and to better understand this, it will be well briefly to consider what had previously been done.

Referring again to the A B C, it will be remembered that an electromagnet will attract a bar of iron as long as it is energised by the passage of a current through the surrounding wires, but as soon as the current ceases, the magnetic action ceases, and the piece of iron is let go. This was the principle of the earliest electric motors, and they were constructed as follows:

Across the surface of a wheel or drum, a number of iron bars (usually 10 or 12) were placed with a space between them three or four times the width of the bar; on either side of the drum an electro magnet was placed, with the poles nearly touching the bars; the spindle of the drum was provided with a cam or other device to make and break the flow of electricity from the battery, so set that when a bar is a little distance away, the magnet is energised, drawing the bar rapidly towards it; but as soon as it gets opposite the electricity ceases, and the impetus of the bar carries it past beyond the range of the magnet, and brings another bar within range, when the magnet is again energised, drawing it forward; thus bar after bar is attracted, and the wheel made to revolve. Little motors of this type can be seen in every shop where scientific instruments are sold, and it was the kind used by Anderson in his demonstrations previously referred to.

For reasons that cannot easily be explained without becoming too technical, this motor is far from economical, and when more powerful machines were wanted a different construction was resorted to—namely, the pulling action of a coil of wire upon a bar of iron described at the commencement of this article.

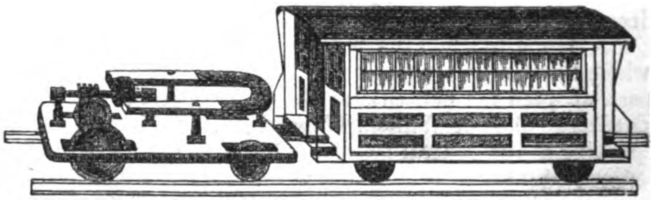
A large motor of this description was constructed in 1850 by Prof. C. G. Page, of the Smithsonian Institute, Washington, which developed over 10 h.p. He sought to apply his motor to locomotion, and he actually constructed an electric locomotive to demonstrate the practicability of his scheme. But he never achieved much success, as might have been foreseen. Among the improvements which Prof. Page introduced was that of making each solenoid double, so that the arms of a U magnet could slip into them, instead of one single bar. As the solenoids attracted most strongly when the cores were almost out of them, he wound his solenoids in short sections, and a sliding commutator, worked by the motion of the cores, successively cut out the sections of coils which the cores had entered, and transferred the current to others ahead of them, and thus the range of attraction was greatly increased.

Prof. Page, it is interesting now to recall, made the trial trip with his electromagnetic locomotive on Tuesday, April 29, 1851, starting from Washington, along the track of the Washington and Baltimore Railroad. His locomotive was of 16 h.p., employing 100 cells of Grove nitric acid battery, each having platinum plates 11in. square. The progress of the locomotive was at first so slow that a boy was enabled to keep pace with it for several hundred feet; but the speed was soon increased, and Bladensburg, a distance of about 5¼ miles, was reached, it is said, in 39 minutes.

When within two miles of that place the locomotive began to run, on nearly a level plane, at the rate of 19 miles an hour, or seven miles faster than the greatest speed theretofore attained. This velocity was continued for a mile, when one of the cells cracked entirely open, which caused the acids to intermix, and, as a consequence, the propelling power was partially weakened. Two of the other cells subsequently met with a similar disaster.

The professor proceeded cautiously, fearing obstructions on the way, such as the coming of cars in the opposite direction, and cattle on the road. Seven halts were made, occupying in all 40 minutes; but, notwithstanding these hindrances and delays, the trip to and from Bladensburg was accomplished in one minute less than two hours. The cells were made of light earthenware, for the purpose of experiment merely, without reference to durability. This part of the apparatus could therefore easily be guarded against mishap. The great point established was that a locomotive on the principle of Prof. Page could be made to travel 19 miles an hour. But it was found, on subsequent trials, that the least jolt, such as that caused by the end of a rail a little above the level, threw the batteries out of working order, and the result was a halt. This defect could not be overcome, and Prof. Page reluctantly abandoned his experiments in this special direction.

In this and all previous experiments the source of energy was an electric battery carried by the car, and the above statement, taken from an American record, shows that practical success is hardly to be expected from batteries so employed. Some other means had to be found for supplying the motor with the necessary energy, and Mr. Thomas Hall, of Boston, United States of America, claims to have been the first to think of using the rails for this purpose. The accompanying illustration is taken from the original woodcut of the locomotive.



HALL'S ELECTRIC CAR.

The block was made nearly 37 years ago, and is thus described in an American book:

"The engine was on the principle of an electromagnet revolving between the poles of a permanent magnet. The armature had a worm on its shaft which matched into a gear attached to the driving-wheels, the latter being insulated by ivory. The track was laid in 5ft. sections, and was above 40ft. long and 5in. wide. Under the platform of the car was a pole-changer attached to a lever. When the engine reached the end of the track it ran against an inclined plane, which reversed the pole-changer and sent the engine to the other end of the track, where the same thing was repeated. Thus the engine was sent automatically from one end to the other. The current, produced by two Grove cells, was, it is well to note, conveyed to the engine by the rails. Mr. Hall says that in 1852 he made for Dr. A. L. Henderson, of Buffalo, a model line of railroad with electric engine depots, telegraph line, and electric railroad signals, together with a figure operating the signals at each end of the line automatically."

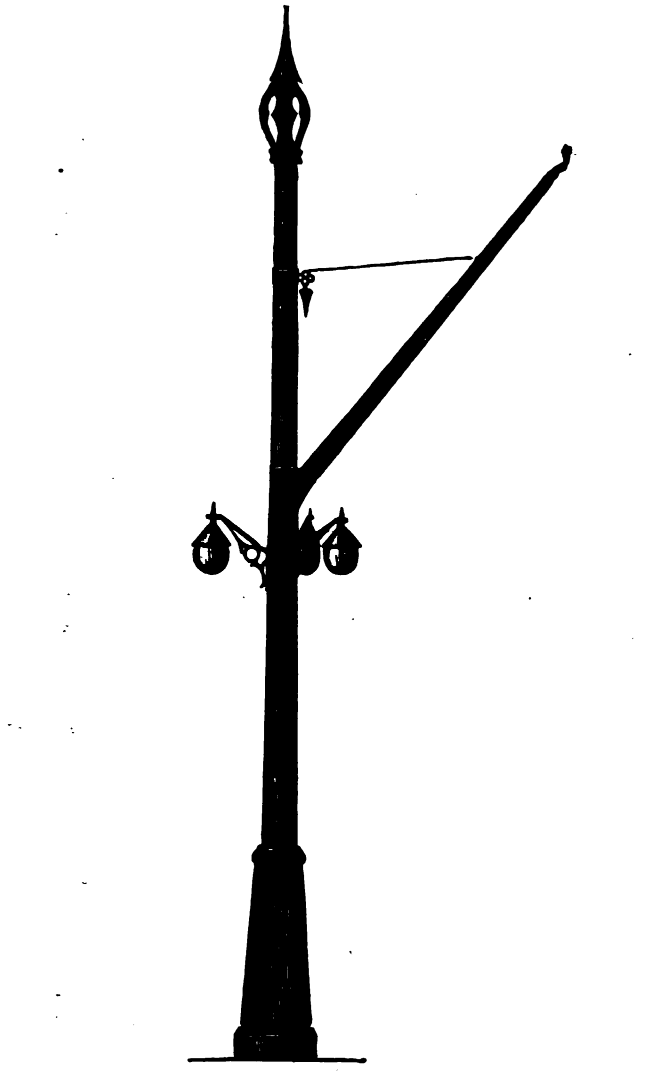
This, he states, was the first model of railroad signals or trains worked by telegraph signals.

Now, it will be easily seen that when the "dynamo" was developed, and it was found that it not only produced electricity, but if supplied with electricity produced power, the field was open for practical work; and with the knowledge of what had already been done, there was no great advance in the electric railway constructed by Dr. Werner Siemens in 1879 and exhibited at Berlin, where the current was taken to the motor on the car by one rail and returned by the other. The little line on the sands at Brighton is, generally speaking, a repetition thereof, and is an excellent specimen of this method, but upon reflection it will be seen that such a plan is inadmissable in the public streets, where horses and carriages are continually crossing and recrossing the rails. For if the rails are conducting a current sufficient to work the number of cars that usually work in a town, then should a horse put one foot on one rail, and another foot on the other rail, it would be instantly killed. This led to the use of the Berlin line being prohibited. And further, if the line is of any length, then the leakage of electricity from rail to rail, through the earth instead of passing through the motor on the cars, would be so great as to render it useless or excessively wasteful. The system, therefore, fails on the three points that are essential for street tramways—viz., safety to the public, efficiency, and economy.

The cheapest and simplest method is to convey the current to the cars by an overhead wire supported on poles, and this is largely used in America, where the questions are, Will it work? and will it pay? and appearances are out of it altogether. Though the employment of overhead conductors would be a great economic gain, if adopted on all our English tramways, it is hardly to be expected that the English public would put up with the unsightly thing used in the States. But the unsightliness is quite unnecessary. The supports can be made orna-

Digitized by Google

mental as well as useful, and there is no reason why this method should not be adopted in country towns.



Pole for Overhead Conductor.

The accompanying sketch illustrates one erected in a seaside resort, for the purpose of demonstrating what could be done.

(To be concluded.)

PHYSICAL SOCIETY.—Jan. 26.

Prof. Fuller, F.R.S., in the chair.

The thanks of the society were tendered to Mr. Freeman for presenting to the library a rare and interesting work, "Réflexions sur la Puissance Motrice du feu et sur les Machines propres a développer cette puissance," par S. Carnot, ancien élèvede l'École Polytechnique.

Dr. S. P. Thompson read three notes on polarised light, entitled respectively, **"The Structure of Natural Diffraction Gratings of Quartz," "Ahren's Modification of Delezenne's Polariser," and "The Use of Two Quarter Wave Plates in Combination with a Stationary Polariser."** Two microscope slides of iridescent quartz (prepared by the late Mr. Darker), which have recently come into the possession of the author, exhibit remarkable peculiarities. Both act like diffraction gratings—one as if the rulings were about 12,000 to the inch, and the other about 26,000 to the inch. On examining the specimens by the microscope, it was found that the parts which exhibited the grating effect showed a spindle-like structure, and by micrometer measurements the dimensions of the spindle-shaped bodias were determined to be from $\frac{1}{1000}$ to $\frac{1}{2000}$ of an inch in diameter and $\frac{1}{100}$ to $\frac{1}{200}$ long. These were much too large to cause the effects noticed, but on closer examination it was found that the bodies were crossed at right angles by fine markings, the distances between which are in close accordance with those deduced from the spectra produced. As a probable cause of the phenomenon the author mentioned a recent paper by Prof. Judd "On the Production of a Lanellar Structure in Quartz by Pressure," and suggested the possibility of making diffraction gratings by such means. Ahren's modification of Delezenne's polariser consists of a total reflection prism, combined with glass plates and black glass mirror, arranged so that the polarised beam is parallel to the original one. The combination of plates and mirror is adopted so as to give enough light and still keep the polarisation sufficiently good. One or two plates laid over the mirror is found to give the best results. The fact that a beam polarised by reflection is not coincident with the original beam, renders it inconvenient, if not impossible, to rotate the polariser, and to overcome this defect the author has arranged two quarter wave plates, one of which may be rotated. The first plate circularly polarises the plane polarised beam, and the second (or rotating one) replane—polarises it in any desired plane. Objects were shown on the screen to illustrate the degree of perfection attainable by using the new polariser in combination with the two quarter wave plates.

A **"Note on Relation between Magnetisation and Speed in a Dynamo Machine"** was read by the same author. In a note presented to the society in June last, it was shown that $\Sigma \rho \, \Sigma R = 4 \pi n C S$, where $\Sigma \rho$ and ΣR are the magnetic and electric resistances respectively, n=speed, and C and S the numbers of armature and field windings. By writing the equation in the form $\frac{4 \pi C S}{\Sigma R} = \frac{\Sigma \rho}{n}$ it is seen that when the electric resistance is maintained constant, the magnetic resistance is proportional to speed.

Prof. Herroun read selections from a paper **"On the Divergence of E.M.F.'s from Thermochemical Data."** The fact that the E.M.F.'s of voltaic cells do not always coincide with calculated values has not hitherto received a satisfactory explanation, and this paper describes an experimental research bearing on the question. Several suggested explanations are given. In some cells the anticipated chemical change does not occur, and some metals become coated with oxide or subsalts; others are effected by dissolved gases, and the hydration or solution of the salts formed may supplement or diminish the E.M.F. of a cell, as well as the absorption or evolution of sensible heat. The question of absorption and evolution of heat is the one chiefly dealt with. If such actions do take place, the total heat evolved by passing a definite current through the cell must depend on the direction of the current, and by enclosing the cell in a calorimeter the difference should be detected. The total heat developed by a current C, in t seconds is $= \frac{C^2 r t \mp e C t}{J}$ where r is the resistance of the cell and e the divergence of the observed from the calculated E.M.F., the − or + sign depending on the direction of the current. In the case of mercury cells, which are usually said to give about half a volt excess E.M.F., the heat was found to be independent of the direction of the current. The heats of formation of mercury salts were then reinvestigated, and the results showed that Julius Thomson's numbers (the ones usually accepted) were greatly in excess of the true values. This accounts for the difference between the observed E.M.F.'s and those calculated from Thomson's numbers. A copper silver nitrate cell was tested in the calorimeter, and the reversible heat effect agreed closely with that deduced from the "thermovoltaic constant," or divergence of observed from calculated E.M.F. Other experiments on tin, lead, nickel, iron, and cadmium cells are described, and the chief conclusions arrived at are: I. The primary factor in determining the E.M.F. of a voltaic cell is the relative heat of formation of the anhydrous salts of the two metals employed. II. That this E.M.F. may set up chemical changes of a different direction and character from those predicated from the heat of formation of the dissolved salts. III. That the E.M.F. set up by I. may be, and usually is, supplemented by the energy due to the hydration or solution of the solid salts, and may have values which accord with the heat of formation of the dissolved salts. The absorption, or evolution, of sensible heat depends primarily on the attraction between the salts and water, combined with the heat of solution. Finally, the author states that the E.M.F. of a cell gives a more accurate measurement of chemical affinity than data derived from calorimetric observations.

COMPANIES' MEETINGS.

CUBA SUBMARINE TELEGRAPH COMPANY.

The thirty-fifth ordinary general meeting of this Company was held last week at the offices of the Company, Old Broad-street, E.C., Mr. Joaquin de Mancha presiding.

The **Chairman**, in moving the adoption of the report and accounts, said it would be remembered that they had carried forward £1,195 from last year's accounts. To that they had been able to add, from the working of the six months under review, £20,708, while there had been an increase of 3,440 in the number of messages. These results, he thought, must be regarded as highly satisfactory. Out of that sum they proposed to pay to pay a dividend at the rate of 10 per cent. on the preference and of 9 per cent. per annum on the ordinary shares—a dividend which, he hoped, would be maintained in the future. The French cable, with which they had been so long threatened, had now been laid from Venezuela to San Domingo, Hayti, and thence to Cuba; and the Directors, with the effective assistance of the manager and secretary, had done all they could to see that the rights of the Company were not trenched upon. They had sent out a supply of cable and other appliances by which it was hoped the manager would be able to effect any repairs in the Cienfuegos-Batabano section of their cable, which was now showing signs that might shortly necessitate them. If any greater injury happened to the cable than they anticipated they might ultimately have to duplicate it, and that was the reason why they had built up so large a reserve fund, which now stood at £84,000, and which, he thought, would be equal to any future emergencies.

Mr. Alexander F. Low seconded the motion, which was carried unanimously, and the dividends recommended were afterwards approved.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the past week amounted to £4,871.

Western and Brazilian Telegraph Company.—The traffic receipts of this Company for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Telegraph Company, were £3,772.

Submarine Telegraph Company.—The accounts of this Company for the half-year ending December 31, 1888, show a balance, subject to audit, which enables the Directors, after adding 15 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 16 per cent. per annum.

NEW COMPANIES REGISTERED.

River Plate Electricity Company, Limited. — Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, London, E.C. Capital £500,000, divided into 49,900 shares of £10 each, and 1,000 shares of £1 each. Object: to enter into and carry into effect the agreements made with Walter Richard Cassels, and with the Rosario Electric Lighting Syndicate, to generate, produce, and deal in electricity or electric force for lighting or other purposes. The first subscribers are:

	Shares.
G. J. Toy, Athole House, Tottenham	1
W. Hamilton, 12, The Avenue, Brondesbury, N.W.	1
H. C. Hudson, 16, Mentone-road, Highbury New-road N.	1
F. Belcher, 3, Ceeley-villas, East Finchley	1
J. B. Birch, 15, Eckington-road, Stamford Hill	1
F. G. Bregan, 11, Thurlow-road, Hampstead, N.W.	1
E. T. Batwright, 23, Sutton-place, Hackney, E.	1

The first Directors shall be appointed by the subscribers to the memorandum of association, and shall each hold at least 50 ordinary shares in the capital of the Company. The remuneration shall be the sum of £1,000 per annum, and one-tenth of the surplus profits remaining after payment of 10 per cent. per annum.

PROVISIONAL PATENTS, 1889.

FEBRUARY 4.

1856. **Improvements in the method of and means for the regulation of dynamos.** John Harold Woodward and Edmund Scott Gustave Rees, 70, Market-street, Manchester.

1961. **Improvements in microphone apparatus for increasing and transmitting sounds by means of earth currents, also by means of chemical batteries.** Robert Henelade Courtenay, 6, Anerley-street, Battersea Park-road, Surrey.

2003. **Improvements in electric-regulating apparatus for use in connection with steam-engines and other motors and dynamo-electric machines.** Alfred Lyster Shephard, 45, Southampton-buildings, London.

2006. **Improvements in apparatus for receiving payments and permitting the administration of electricity in exchange therefor.** Henry Harris Lake, 45, Southampton-buildings, London. (David Richmond Johnston, Belgium.)

FEBRUARY 5.

2044. **An improved type writer and telegraphic apparatus, applicable in combination therewith.** Carl Hans Wolf Stielow, 433, Strand, London.

2056. **Improvements in electric stop valves.** Robert Wellens, 53, Chancery-lane, London.

2066. **Improvements in the manufacture of electrodes for secondary batteries or accumulators.** Leonard Paget, 45, Southampton-buildings, London. (Complete specification.)

2071. **Improvements in electric systems.** Anthony Bernerd Ferdinand, 77, Chancery-lane, London, W.C. (Complete specification.)

2079. **An improvement in plates for secondary voltaic batteries.** Arthur Harry Norman, 28, Southampton-buildings, Chancery-lane, London, W.C.

2080. **Improvements in and relating to portable electric batteries and in electrodes therefor.** Henry Harris Lake, 45, Southampton-buildings, London. (Lucius Thaddeus Stanley, United States.) (Complete specification.)

2082. **Improvements in or relating to telephone call-boxes.** William Phillips Thompson, 6, Lord-street, Liverpool. (Amenzo Griffith, Henry Anderson Burbank, and William Herbert Jordan, United States.)

FEBRUARY 6.

2137. **Improvements relating to magnetic telephony.** Eugene Gwosdeff, 6, Bream's-buildings, Chancery-lane, E.C.

2141. **An electric meter.** Caspar Baur, 28, Southampton-buildings, Chancery-lane, London, W.C.

2145. **An improved electrical apparatus for lighting cigars or pipes, and for other purposes.** William Green, 54, Fleet-street, London, E.C.

2151. **Improvements relating to electric batteries.** William John Woodward and Frederick Henry Judson, 45, Southampton-buildings, London.

FEBRUARY 7.

2168. **Improvements in or appertaining to electric meters.** William Phillips Thompson, 6, Lord-street, Liverpool. (Henri Owen Tudor, Grand Duchy of Luxemburg.)

2169. **Improvements in or relating to electric signalling apparatus for railways.** William Phillips Thompson, 6, Lord-street, Liverpool. (Eugène Jacques Jérome de Baillehache, France.)

2176. **Improvements in materials and methods of preparing the same for bases of electrical instruments and for other electrical purposes.** Frederick Lawrence Rawson, 11, Queen Victoria-street, E.C.

2199. **Improved electric periodical contact making switch.** Arthur Douglas and Frederick Smith, 4, Dane's Inn, Strand.

2205. **China or porcelain cap or socket for incandescent electric lamps.** Edward William Lancaster, Albert Works, Graham-street, Birmingham.

2206. **Improvements in the electro-deposition of metals, specially applicable for depositing on fragile articles or coating, plating on, or forming articles of irregular surface.** Thomas Phillip Christopher Crampton, Edward Gardner Colton, and The Medical and Scientific Apparatus Company, Limited, 38, Holborn Viaduct, E.C.

2231. **Electric fog and danger-signalling apparatus for railways.** Charles Adams-Randall and Walter Herbert Cook, 15, Montpelier-square, Brompton, London.

FEBRUARY 8.

2243. **Electrical connections attached to railway locomotives, and to connect to a metal plate affixed near the rail, arranged by a metal wire brush.** William Andrews, 34, Broad-street, Nottingham.

2252. **The improvement of instruments for measuring currents of electricity.** John William King, 13, St. John's-square, Clerkenwell, London, E.C.

2276. **Improvements in the construction and arrangement of primary batteries.** Emile Guitton, 166, Fleet-street, London. (Marcel Sappey, France.) (Complete specification.)

2297. **Improvements in primary and secondary transportable galvanic dry elements.** Castle Smith, 54, Fleet-street, London. (Wilhelm Louis Frederik Hellesen, Denmark.)

2299. **Improvements in apparatus for measuring electric currents.** Lucien Alfred Wilhelmine Desruelles and Raphael Fénelon Ovide Chauvin, 45, Southampton-buildings, London.

FEBRUARY 9.

2313. **Improvements in means of applying electricity for therapeutic purposes.** Henry Newman Lawrence, 24a, Regent-street, London, S.W.

2331. **An improved apparatus for economically effecting the double decomposition of certain substances by the aid of electricity.** William Henry Dowland and Walter Mills, 54, Glengall-road, London, S.E.

2349. **Improvements in and relating to electric appliances for illuminating the dials of clocks and watches.** Thomas Hoxland White, 20, High Holborn, London, W.C.

SPECIFICATIONS PUBLISHED.

1881.

3369. **Electric lighting.** Hedges. (Amended and complete specification.) 8d.

1888.

609. **Determining poles of electrical circuits, &c.** Berghausen. 8d.

2666. **Dynamo machines, &c.** Sherrin. 8d.

3590. **Electrical transformers.** Statter. 8d.

3710. **Electro-magnetic motors.** Tweeddale. 8d.

NOTES.

Blackpool.—There is some probability of a scheme for the extended lighting of the Blackpool Promenade by electricity being agreed upon.

St. James'.—The St. James's Vestry adhere to their resolution not to consent to the application of the House-to-House Company for a license.

Karlsbad.—A central station is to be put down at this watering place by Messrs. Ganz and Co., similar to the station just erected by them at Marienbad.

Electric Railway at Baden.—Plans have been prepared for an electric railway to be shortly constructed between Baden and Vöslau, Lower Germany.

Electric Sugar.—The electric sugar gang are now in gaol. It is stated that there is still some £16,000 assets available, enough to pay a dividend of 16 per cent.

Electric Tramway for Spain.—The Brush Corporation have booked a contract for the application of their system of electric traction to an important tramway line in Spain.

Lille.—The Municipality of Lille has entered into arrangements with the two gas companies in the district for the construction of two central stations for electric lighting.

Submarine Telephone.—The first submarine telephone line is being established between Buenos Ayres and Montevideo by the Belgian company, Mourlon and Co. The cable will also transmit telegraphic messages.

Rome.—The Municipality of Rome are considering the question of public lighting by electricity. They contemplate acquiring the present central stations of the various companies, and extending the plant so as to light the entire city.

Electric Railway Crossing Signals.—Messrs. Siemens and Halske have introduced on the German railways a system of electric bells for level crossings. When a train is within 1,500 yards of the crossing the bell rings violently until the train has passed the crossing, giving ample warning of danger.

Electric Light in the Lake District.—Steps are being taken to form an electric light company at Keswick, the project having the support of several of the most influential residents. A survey has been made, and it is expected that the works will be on the banks of the Greta, the river supplying the motive power. A prospectus will be issued to the public shortly.

Electrically Welded Bale Ties.—In the South American cotton-fields large amounts of waste ends of the iron hoop used for tying the cotton bales have hitherto been wasted or sold for scrap. The Thomson-Houston Company have applied one of their electric welding machines to utilise these short ends by welding together into sufficient lengths. The saving thus introduced is very considerable.

"Brush" Combined Electric Light Sets.—The Anglo-American Brush Electric Light Corporation, Limited, have just secured an important contract for the supply of about 40 sets of combined engines and dynamos of their special design, and have now in hand orders for nearly 50 sets of apparatus of this pattern. The design has met with much favour from the European Governments since its introduction, and has been largely adopted for lighting ships of war and other vessels.

Milan.—The following particulars are given in *Elettricita* of the central station in Milan: 1,075 incandescent lamps of 8 c.p., 4,839 of 10 c.p, 6,817 of 16 c.p., 158 of 32 c.p., 1 of 50 c.p., 227 Thomson-Houston arc lamps, and 152 Siemens arc lamps, making a total of 12,890 incandescence and 379 arc lamps. The station also supplies a certain number of electric motors, for which a current is supplied equal to the rate of ½d. per ampere-hour, which comes out about 4d. per horse-power per hour.

The Telephone on the Railway.—A practical experiment was lately made on a French line of railway to show that communication by means of the telephone may be made from a disabled train to the neighbouring stations. On the line from Noyelles to Saint-Valery, where a telephone wire runs along the line, a train stopped in open country. With the aid of a portable telephone connected to the wire, communication was then made with the two stations before and behind, which acted perfectly.

Proposed Central Station at Sofia.—The Electric Section of the London Chamber of Commerce notifies us that Her Majesty's Agent and Consul-General at Sofia reports that the municipality of that capital has decided to light the streets of the town and the ministries, consisting of ten houses with about 20 rooms in each, with electric light. Tenders for that purpose will be received by the Municipality of Sofia up to the 13th of April; and it is desirable that communications should be made in French or German if possible.

Telegraphists for the Cape.—We understand that the Cape Post Office authorities have recently asked Mr. Walliker to recommend several telegraphists for service in the colony, with the result that in the course of a few days five expert and experienced telegraphists, of from five to nine years' service, will be transferred from the Birmingham Post Office. The terms of the engagement are such as appear to offer them favourable opportunities of advancement, in addition to which their service under the Home Government is allowed to count for pension.

Houses of Parliament.—A small steam-engine and dynamo, capable of working about 120 extra electric lights, have been erected at the Houses of Parliament, thus increasing the total number in the building to 620. Seventeen of the additional lights have been placed in one of the reporters' writing-rooms, and the remainder are supplied to the members' entrance lobby, staircase, and corridor. After Easter the light will probably be extended to the Commons' lobby, St. Stephen's Hall, the offices immediately adjoining the House, and several of the Ministers' and reporters' rooms.

Electricity in Mining.—An interesting paper was read by Mr. F. Brown on the transmission of power by electricity before the annual meeting of the South Staffordshire Mining Engineers, dealing with the wider application of electricity to mining. Mr. Brown advocated the use of electrical coalcutters, which could be mounted on a truck and taken to any part of the mine by two men. Mr. Brown gave several instances of the successful application of electricity to mining in this country, and cited one instance in which it was estimated that £500 a year was saved by its use

Digitized by Google

Electric Fire Alarms in Paris.—A new arrangement of electric fire alarms has been designed by M. Petit, controller-general of telegraph lines in Paris. With the old forms of fire alarms it was only necessary to break the glass and press a button, and many false alarms were given by practical jokers. In the new applications a little door has to be opened to give the alarm, and the same movement puts in action a strong electric bell placed inside the box. It is impossible to stop this bell for some moments, and the giving of the alarm by this means renders it impossible for a false signal to be sent without the public and the policemen being aware of it.

Dry Storage Batteries.—It may be remembered that in describing Dr. Gassner's dry battery, it was stated that the battery could be reversed and used as a storage battery. An accumulator of this nature is being brought out in Berlin under the name of the Welcker storage battery, having a jelly instead of liquid as electrolyte. The battery is said to be a very light one in weight, and it has been proposed to form a company to distribute stored electricity by carts for electric light and other purposes. No very exact details of the enterprise are yet published, but if a practical dry storage cell could be introduced, there would be a large field of usefulness for it.

The New Central Railway at Glasgow.—Arrangements for the construction of a new central line at Glasgow will be commenced shortly. The engineers mentioned for construction are Messrs. George Miller Cunningham, Edinburgh, and Charles Formans, Glasgow, and the consulting engineer will be Mr. Wolffe Barry, London. The new railway will extend from the east to the west end of Glasgow, running for the greater part of its length in line with the River Clyde and under several of the principal thoroughfares. It is seven miles long, and of this distance about six miles is underground. The present underground railway company in London is meditating the adoption of electric traction, and the Southwark Railway, now building, has definitely adopted electricity. Would it not be well for the Glasgow Central Railway to begin in the direction which all underground city lines will eventually have to adopt?

A New Notion in Casing Junctions.—We are always ready to welcome any little improvement in the details of electric light installations, and we are pleased to notice an improved junction in the wood casing for wires, which has been sent to us by Mr. Fred. Bathurst, of 111, King Henry's-road, N.W. At any junction of wires to the mains, one branch wire has always to cross the main of opposite potential. To make this quite safe is a point worthy of greater attention by electrical contractors, and in the device of Mr. Bathurst we have a small semi-circular block of wood with one groove in it, which is placed upon the casing at the point of junction. The branch wire, after the joint is made, crosses in this groove quite away from the opposite main, and a wood cover, in the form of half a ring, turned to match the casing, fits down over this. The joint reminds one of the little curves crossing the opposite wire always drawn in diagrams of electric wires, and it makes a junction perfectly safe from possibility of danger.

Value of "V."—The measurement of "*v*" by Sir William Thomson and Profs. Ayrton and Perry, communicated to the British Association at Bath, was too small (292) on account of the accidental omission of a correction regarding the effective area of the attracted disc in the absolute electrometer. When this correction is applied, their result is brought up to 298, which exactly agrees with Profs. Ayrton and Perry's previous determination by another method, in Japan. Prof. J. J. Thomson's result is 296·3. It is understood that Rowland found 299. The result of Sir William Thomson's latest observations, founded wholly on the comparison of electrometric and electromagnetic determinations of potential in absolute measure, is 30·1 legal ohms, or 31·04 Rayleigh ohms. Assuming, as is now highly probable, the Rayleigh ohm is considerably nearer than the legal ohm to the true ohm, the result for "*v*" is 300·4 million metres per second. Sir W. Thomson does not consider that this result can be trusted as demonstrating the truth within ⅓ per cent.

The Thomson-Houston Systems.—The Thomson-Houston Company is one of the most far-reaching organisations of electric manufacturers, electric light—arc and incandescent—electric railways, and the welding system. These have been spread abroad through the length and breadth of the world with astonishing success. Especially is this lately the case with electric railroads in the States, and intending enterprisers in tramways would do well to inspect the catalogue of the Thomson-Houston electric railway system, just issued by Messrs. Laing, Wharton, and Down, New Bond-street. It is most handsomely got up, and illustrates views of electric railways now working successfully at Toronto, Lima, Port Huron, Scranton, Ansonia, and other places in America, with details of the system and working expenses. The Thomson-Houston electric light catalogue, now ready for issue, we have already fully noticed—a handsome and comprehensive book. The catalogue, or prospectus, rather, of the welding system, is also issued, and contains information with reference to the applications on every side of this, the latest branch of electrical industry.

Underground Wires on the Continent.—It is reported that an interesting case will shortly occupy the attention of the law courts of Luxemburg. The city of Luxemburg granted, in 1864, to the local gas company the exclusive right of laying down gas-pipes in the streets, and of supplying the city with gas. The Amsterdam representatives of the firm of Siemens Bros. lately made arrangements to provide Luxemburg with the electric light, and asked the municipality for authority to erect overhead wires or lay down underground conduits, and permission was granted without hesitation. The gas company considers that this permission constitutes a breach of contract, and have requested the municipality to have the wires removed, claiming damages at the same time. The company assert that the intention of the contracting parties in 1864 was to give to the company the exclusive right of lighting the city. The municipality reply that this monopoly only applies to gas. As the introduction of the electric light depends upon a decision on this point, the result of the application of the company to the courts is awaited with some degree of eagerness.

Telegraph Line Inspection.—Colonel Mallock's tour of inspection of the Indo-European telegraph line has come to a close, so far as Persia is concerned. Leaving Simla on October 20th, the Director-General of Telegraphs arrived at Bushire at the end of that month, and began his long ride "along the wires." He reached Teheran, by the way of Shiraz and Ispahan, on December 3rd, having ridden 717 miles in 32 days, including halts for inspection purposes at various stations. After a stay of 16 days at Teheran, he started again for Bagdad by

Digitized by Google

the Koom route, riding the 500 miles in 24 days. He chose this route to shorten his journey, and to avoid the snow on the highlands between Teheran, and the Persian Gulf. Colonel Mallock was due in Calcutta about Feb. 10th. It has been fully decided that he is to have a year's extension of office, the reason being that the Government of India, having only lately acquired the Indo-European telegraph, find it desirable to utilise his personal knowledge of the line. Otherwise he would be obliged to retire, under the 55 years' rule. Colonel Mallock will still only be officiating as director-general, as Sir Lepoc Cappel's leave does not expire till December next.

St. George-the-Martyr Vestry.—A special meeting of this Vestry was held on Tuesday, prior to the transaction of the ordinary business, for the purpose of considering the following recommendation of the Roads Committee: "That this Vestry assent to the granting of a license by the Board of Trade to the House-to-House Electric Lighting Company, Limited, authorising that company to supply electricity within this parish." Mr. Stevens, the engineer to the company, was in attendance, and made a lengthy statement as to the system adopted by the company. He explained that the company used underground mains, and, as to street lighting, said the company would be prepared to supply the parish at the same rate as, if not less than, the gas company. Mr. Layman moved, and Mr. Emary seconded, that the recommendation of the Roads Committee be adopted. In answer to Mr. Titcomb, the clerk (Mr. W. H. Millar) said the license would only give the company powers for seven years. Mr. Brazier asked whether, in the event of the company coming into the parish, their property would be liable to assessment. The Clerk : Certainly. The motion for the adoption of the committee's recommendation was adopted unanimously.

Army Signalling and Torpedo Warfare.—The means of army communication in the field, as well as the development of torpedo warfare, have during the last decades made such vast progress, that both may be regarded as new subjects of military science. An index of publications on military communications and on torpedo warfare, compiled by R. Von Fischer-Treuenfeld, late Director Army Telegraphs, etc., is published by Alabaster, Gatehouse, and Co. (80 pages, 3s.), and should prove very useful to military engineers. The first part contains 680 titles of literary works, which are grouped in 29 classes, comprising the following subjects: Military telegraphy, signalling, field post, military aeronautics, military photography, land and submarine mines, torpedo boats, electric light for military purposes, ballistics, lightning dischargers for military buildings, range-finders, and cryptography. The second part contains 340 names of the authors of the publications, arranged in alphabetical order. The index has been compiled in order to facilitate researches with regard to the above-mentioned branches of military science, and thus to further their study and practical development, and the titles of publications are given in their original languages, so that the index may be looked upon as an international one.

Woodward Storage Car.—The Detroit battery is used on the new storage car made by the Woodward Electrical Company for Brooklyn. The car is equipped with 84 cells, with hard rubber jars, having a capacity of 300 ampere-hours. Each cell has 17 plates, but a larger size, containing 19 plates and having a capacity of 400 ampere-hours, will shortly be placed on the car. A series motor is placed under the car, which is mounted on six wheels, and the power is transmitted from the motor to the axles by means of two friction wheels. Two pairs of wheels are movable, and connected to a lever on the platform. When the said lever is operated the movable pair of wheels are brought up to the friction wheels, attached to the motor shaft between them, and the car is thus set in motion. By this means the start can be made very gradually, though quickly, and without jar or shock. On the platform are also placed a main battery switch and regulating switch. The arrangement is such that when the brake lever is applied the batteries are automatically cut out at the same time. When starting, the brake lever is released by the foot, while at the same time the batteries are again automatically placed in circuit, and the car starts with the full power. The car is brilliantly lighted by three 16 c.p. incandescent lamps.

Brussels.—The city authorities at Brussels, says the *Bulletin International de l'Electricité*, have already received several propositions with regard to the electric lighting of the central portion of the town. The American Thomson-Houston Company, represented in Belgium by M. Humbert, offer to light gratuitously the Boulevards Anspach and Du Nord, on the condition that the town authorise them to lay wires under the public streets for lighting the large buildings round the Bourse and the market. For this supply the Thomson-Houston Company have made arrangements to construct a central station in a neighbouring building. Two other generating stations would be constructed, one in the rue des Bouchers, the other in the rue Royale. The first would light the Galeriès Saint Hubert, and the whole of the buildings in the vicinity. It is stated that M. Vlierboom had also proposed to establish a station here, and had secured a large number of orders, but when he began to fix the boilers and dynamos the town authorities intervened, because the site of his station had been chosen without their consent. This project has now the support of a group of financiers, and the Thomson-Houston Company will probably find them serious competitors. The other proposed station by this company would light the banking offices of the rue Royale as well as the Theatre du Parc.

Electric Power in India and the Colonies.—The *Indian Engineer* calls the attention of its readers to the spread of electric railways in America, with the hope that it may suggest some action in this direction in India. The water power, for instance, it is suggested, which now runs to waste along the Darjeeling Railway would possibly go far towards working this line by electric traction, and at many of the hill stations there is ample power now running away uselessly, which might be turned to good account in lighting or other purposes. There is no doubt that they are moving far too slowly in this direction, not only in India, but in all our colonies; but this is to a great extent the fault of our English electrical engineers. When we compare the attitude of the industry in England with America, we might do well also to look at the map of the two countries, and we then realise what we too often forget—that in new undertakings England's greatness in commerce depends, and must depend, to an enormous extent upon its colonies, the British possessions generally. When English electrical firms attempt to exploit this vast domain in the same manner as the American companies do the States, then there may be some possibility of English electrical activity rivalling that of the New Continent. England is England

Digitized by Google

quite as much by the extent of its colonies as by the activity of its inhabitants, and it would be well if electrical engineers recognised this attitude to a far greater extent than at present they appear to do.

Progress at Deptford.—The large transformer station, on the Ferranti system, at Deptford is now the point of attraction of all eyes in the electrical world, and all are anxiously awaiting the start with a similar feeling to that often enough experienced by electrical engineers in the early days on the starting of a new installation. "Lighting up" is a common enough event now, and we know exactly what to expect, but the arrangements for lighting up here are of sufficient grandeur and novelty to bring the same feelings into play again. We are pleased to be able to report that the work at Deptford is actively progressing. The roof has been on some time, and the two "small" engines of 1,500 h.p. each are laid down. Boiler-power to the extent of 6,000 h.p. is ready, but the dynamos and electrical connections will not be placed till the last, when the building is dryer. None of the 10,000 volt mains have yet been laid. This, however, will not be a long job, and will be done in as short a time as possible, so as not to inconvenience the railways along which they are to be run. Arrangements are made for a start about the end of April, and the wires will first be led to Charing Cross distributing station, and connection made from there to a large number of houses to the number of many thousands, which are already wired for the light. The machinery at the Grosvenor will not be disconnected for some little time, till the outstanding needs have been fully supplied.

The Electric Engine on the Elevated.—The electric engine "Benjamin Franklin" has been running continuously since January 28 (with the exception of two days during the strike) on the Elevated Railroad, New York, taking its place among the steam-engines, and winning golden opinions from the absence of smoke, steam, and cinders. It draws the standard train of four long cars, with average load of passengers, weighing in all 80 tons, with gradients of nearly 2 per cent., with an average speed of 15½ miles per hour, as against 13¼ of the steam-engines. The electric engine alone at times attains the speed of 30 miles an hour, developing over 120 h.p. No mishap or reverse of any kind has occurred; no heating of journals, magnet coils, or commutator. It takes its place between two ordinary trains and runs on schedule time. It does not, however, stop between the termini, not yet being furnished with air brakes, and stopping by hand brakes would absorb too much time. At present no delay is occasioned, and no trip is missed. Three of the leading financiers of America—Messrs. Gould, Sage, and Dillon—are at the head of the Elevated Railroad, and are carefully investigating the system from the purely commercial point of view. Numerous careful experiments and tests are being made with the current, load, and steam-engine diagrams, which may be published shortly. If this powerful company decide to adopt electric engines for their city traffic, it will give an immense impetus to the spread of heavy electric railways throughout the world; and we commend their action to the notice of Sir Edward Watkin and the Electric Traction Company.

The Submarine Cables.—The Central News says: "The attitude of France in regard to taking over the cables of the Submarine Telegraph Company has placed the British Post Office in a position of considerable difficulty. M. Coulon insists on the laying of new cables instead of taking over the old ones, and has just given formal notice that France intends to grant to the Submarine Company a further prolongation of the term for the working of the cables between the two countries until the difficulties existing between the two Governments are removed, or until new Anglo-French cables have been manufactured and laid. This practically makes it impossible for the British Post Office to take over the working of the French cables on 1st April, the date previously arranged. On the other hand, the Post Office is bound, by agreement, to commence working the German and Dutch cables by the above-named date, and if those Governments insist upon their contracts being rigidly adhered to, the continental traffic in telegrams will be divided between the Submarine Telegraph Company and the General Post Office, a state of affairs almost certain to lead to friction in the working. Last week a conference was held at Cologne between the heads of the Telegraph Departments of Germany, Holland, Belgium, and Great Britain (Mr. Lamb representing the British Postal Telegraphs), to arrange for the further working of the wires between Great Britain and those countries; but whether any revision of existing arrangements was then definitely decided upon has not yet transpired. From the opinion of experts, however, it is believed to be impossible for the Government to take over the working of the German and Dutch cables by April 1, and the same opinion is even more strongly held in respect to the Belgian cables."

Electrical Stress.—Prof. Rücker, at the Royal Institution, last Friday night, delivered a lecture, in which he discussed the effects of the introduction of electrified conductors into non-conducting or nearly non-conducting liquids. The subject had been studied by Faraday, Kerr, Quincke, W. Holtz, and others, but various difficulties had prevented some of the more striking phenomena being shown in experimental lectures. The lecturer and Mr. Boys last year devised a set of apparatus which made the exhibition comparatively easy. Faraday's magnetic lines of force could be shown by the aid of iron filings; but the corresponding experiment in the case of electrical lines of force in a liquid was more difficult, because the liquid was thrown into violent agitation, and the solids used tended to cluster about one of the poles. These points were illustrated by experiment, and the lines of force were realised by means of powdered antimony immersed in ether. The tendency of the lines of force to become shorter, and to separate the one from the other, was also illustrated, and from this the fact was deduced that a body subject to electrical stress assumed temporarily a kind of crystalline structure. Kerr's and Quincke's experiments on the passage of polarised light through carbon bisulphide were then discussed. Kerr's experiments depended upon the fact that since the electrical stress was a tension along the lines of force, and a pressure at right angles to them, a substance in which such a stress was produced assumed a semi-crystalline condition in the sense that its properties along and perpendicular to the lines of force were different. Light was therefore transmitted with different velocities according as the direction of vibrations coincided with or was perpendicular to these lines, and the familiar phenomena of the passage of polarised light through crystals might be imitated by an electrically-stressed liquid. These researches were exhibited with various modifications and extensions.

Electrical Signalling on Board Ship.—The advantages which the electric signalling apparatus of Mr. J. B. Willis offers over mechanical and pneumatic contrivances are so marked that the Admiralty have, says the *Pall Mall Gazette*, given orders for fitting a number of vessels with it. A commander hitherto has not always been certain that his orders to the engineers or steersman have been observed and carried out, but by this telegraph the signal must be acknowledged, so that the officer is ensured against mistakes. The instrument works to a large extent automatically, the simple movement of a handle doing all that is required, so that there is less to do, as well as absolute certainty on the part alike of the officer, the engineer, and the man at the wheel. The relief is so great that the captain of a merchant steamer who has had the apparatus in use for eight or nine months has declared that he would sooner be at the expense himself of fitting his vessel with the system than return to the mechanical telegraphs. In addition to the engine-room and steering telegraphs, there is a revolution order telegraph for signals between the captain and engineer in giving the number of revolutions at which the engines are to work. This will prove of great utility in warships for fleet and line manœuvres, and would be a great advantage in all ships, especially in entering port, and where it is necessary to have the engines quickly changed by a few revolutions—for instance, in cable laying and repairing, or in sounding operations. A number of transmitting instruments can be worked to a single receiver in the engine-room, so that they can be fitted up in various parts of the ship. The cable connecting the instruments is laid under the water line in ships of war, so that they are free from danger in action, and if one or more of the instruments were destroyed, the efficiency of the others would not be impaired. The apparatus, as already stated, is being fitted up in a number of Her Majesty's ships, and the naval attachés of foreign Powers have been inspecting the installation which has been fitted up at the works of the manufacturers, Messrs. Elliott Bros., St. Martin's-lane.

Plymouth Tramways.—An important meeting of the Plymouth Town Council took place last Friday to consider the report for the formation of a new tramway. The report of the Works Committee was presented with the agreement with the new tramway company. The use of locomotive steam-engines is prohibited. Certain streets are to be widened, and two years are allowed to do the work, and the promoters are to prove that £8,500 of the capital has been offered and accepted before commencing work. The question of horses, cable, and electricity was freely discussed, some members being in favour of the old-fashioned horse; others in favour of the cable system—quoting the example of Birmingham, evidently not knowing that Birmingham has decided for electric traction. Considerable interest was evinced for electric tramways, and a telegram was read from Gravesend stating that a trial of the electric system there was satisfactory. Mr. May, in reply to criticisms that horses were not accustomed to see a car coming along by itself, referred to the electric omnibus which had been run in London. Mr. Moon, speaking on the motive power to be used, said he believed in the future that tramways would be worked by electricity, and not by cable power. No company would be so ill-advised as to lay out an engine-house and cable for the whole of their system, when in the future electrical power would be generally adopted. Alderman Harland expressed the sentiments of the Council when he said that they ought to have the report of some responsible authority as to the working of the motive powers mentioned, as at present they knew very little about them. They ought to apply to the proper authorities in other towns where the systems were used, and ascertain whether there was any objection to their being introduced into a town like Plymouth. The mayor then put the motion, leaving it open to adopt either cable or electricity, and the report was unanimously adopted. We shall look to our electrical tramway engineers that Plymouth, having the chance to start fair with an electric tramway, has the best means of judging of its advantages over other means of traction.

Drake and Gorham's Catalogue.—Almost every private installation, and many public ones, have now a set of secondary batteries as a necessary adjunct. Of electrical engineers fitting up these batteries very few have had anything like the experience of Messrs. Drake and Gorham, who have a working arrangement with Elwell-Parker, Limited, under royalty to the E.P.S. Company, to manufacture accumulators to their own specification and embodying their patented improvements. Everyone, therefore, who has to use secondary batteries would do well to secure a copy of the new catalogue which Messrs. Drake and Gorham have just issued, in which these batteries are fully illustrated and described, together with all the accessories they have found necessary to devise for the convenient manipulation of battery installations. The improvements claimed for the "D & G" cells are the process of "burring" the lips of the cavities; the use of a special alloy unoxidisable in acid; the dense nature of the grids due to the rolling process; patent method of holding the lugs; use of ebonite insulating frames so arranged that the lugs of positive and negative plates are placed at different heights to prevent oxide causing short-circuiting; and the use of Elwell-Parker special oxides, which prevent blistering. Prices are given for various sets of complete batteries. Drake and Gorham's patent excess indicator is also illustrated, and of switches, a number of very useful forms of their ring contact switches, a peculiarly solid and satisfactory switch for heavy currents. A combined charge and discharge switchboard, with these switches, is very useful, and this, mounted on the same base with cut-outs, steelyard ammeter, etc., is illustrated in various forms for battery installations. Besides these, we have Drake and Gorham's battery testing voltmeters, with long range, from 0 to 3·5 volts, a very useful instrument; and hydrometers for testing the acid, one form of which reads from 1·140 to 1·180 over a 5in. scale, giving great facility for delicate testing. Their patent disc ammeter, a recent form of instrument with a solid copper tube split in screw form as conductor, possesses good features of simplicity and of accuracy in the neighbourhood of other currents, and is a solid and convenient instrument. We note the list of Captain Cardew's instruments, the patents for which have been purchased by Messrs. Drake and Gorham. These include the celebrated Cardew voltmeter, a safety switch for high-tension current; electrical speed-counter, to indicate speed of rotation at a distance; and a recording voltmeter of great utility for engineers of central stations. Along with the catalogue Messrs. Drake and Gorham also issue, in neat pamphlet form, their instructions for running secondary batteries, in which the necessary directions are carefully and fully described with illustrations. This contains, in a few sheets, a considerable amount of very useful information about the management of accumulators.

ON CERTAIN PHENOMENA CONNECTED WITH IMPERFECT EARTH IN TELEGRAPH CIRCUITS.*

BY A. E. KENNELLY, ASSOCIATE.

Since the earliest days of commercial telegraphy—the days that first reaped the labours of Sœmmering and Steinhill, Gauss and Weber, Cooke and Wheatstone—the substance of our planet has been impressed into such universal conducting duty, that now scarcely a circuit closes, be it across an ocean or be it across a meadow, but embraces its share of the earth in its completion; and the task thus imposed is generally borne so readily and executed so perfectly that, until the existence of the eavesdropping telephone, it was really doubted whether in truth the earth could or did conduct the current entrusted to its care.

Considering, then, the great obligations telegraphy owes to the earth—that the existence of some hundred thousand miles of metallic conductor, at present in daily telegraphic operation, implies in a certain sense the corresponding twin existence of an equal length of terrestrial conductor ready made by Nature; that it has even been possible to telegraph over a space of which the metallic conductor formed but a very proper fraction—the cases that are met with where the earth fails to fulfil its part excite astonishment more by their rarity than by the force of those laws whose mandates they obey.

Almost all such cases of imperfect earth are, we know, traceable to some fault either in the earth connection itself or in its immediate neighbourhood; and a remedy is found by adequately increasing the surface area of the buried electrode, or the conductivity of the ground in its vicinity; so that they are not really failures of the earth's conduction, but failures in securing the necessary degree of connection with the earth's mass.

There are, however, other cases, brought about by conditions more deeply seated and more rarely met with, which will occupy our present attention.

A paper by Mr. James Graves, "On Vibrations due to Earth-Plates," was read before this Institution in January, 1875, and it will be seen that the phenomena therein described are probably related to those that will be presently detailed. Although the matter has not occupied the Institution's direct attention since that date, no doubt some of its members will have independently observed similar phenomena, and can bring forward such additional evidence as cannot fail to elucidate a subject at once replete with technical interest and important practical bearings.

These phenomena are presented by the Atlantic cables of the Direct United States Cable Company, with whose permission the facts are laid before the Institution.

The two cables of this company terminating in Nova Scotia run to Ireland and to Rye Beach respectively. Their landing place was originally Torbay, N.S., but they were removed thence to Halifax some eighteen months since.

The diagram shown supplies the outlines and main features of Halifax Harbour. The Irish cable was first brought into the cable-house, situated 40ft. above high-water mark, upon the beach opposite George Island, on the 23rd October, 1887, and it was put in communication with the town office by means of a line cable and a return earth cable, side by side, in an iron pipe. Each cable was 0·7 knot long, had a resistance of 8·3 ω, a capacity of 0·25 φ, and a high insulation. The line cable united with the Irish shore end through lightning guards, while the earth cable made good soldered connection with the shore end sheathing.

Some vibration of the mirror spot, due to electrical disturbance, was noticed on first joining up the circuit at the office through instrument and condensers, but this was at the time attributed to faults which then existed in the cable. Beyond this continual vibration, no noteworthy feature occurred until six days later (29th October), when the Rye Beach cable was landed at the same cable-house, and joined up with the office by a precisely similar pair of cables running through iron piping in the same trench with the other above mentioned. This cable is worked on the double-current Morse system without condensers, and it was immediately noticed that sending to Rye Beach with 12 volts of battery power visibly disturbed the mirror spot on the Irish circuit, although each cable made earth separately through its own sheathing *via* the insulated return cables to the beach. Receiving from Rye Beach did not disturb the mirror, nor did the operation of the Irish cable in its turn affect the less delicate apparatus of the Morse circuit.

The only remedy that could be, or has since been, practically available, without adding to the retardation of the circuits, was the reduction of the Morse battery power on one hand, and the sensitiveness of the Irish mirror on the other, as far as the operation of the circuits would conveniently permit.

After the removal of the faults in the Irish cable, the vibrations of the mirror still continued, and it was noticed that not only these, but periods of disturbance coincident with local meteorological changes, affected the signals more than had been on record with the same circuit when worked previously from Torbay. On this was superposed the interference caused by transmission on the Rye Beach circuit, and the combined disturbance at times made the mirror signals difficult to read.

The Rye Beach shore end was at first laid very near to the Irish cable, and actually over it at one or two points. The cables were, however, subsequently separated, although they still necessarily lie at different points in close proximity. This separation of the cables was found to have sensibly lessened their interference.

The operation of the cables from the cable-house, instead of from the office, was found to produce no change in the nature or degree of disturbance, while experiment failed to produce any visible interference between the trenched cable circuits from office to beach, even on the most delicate instruments.

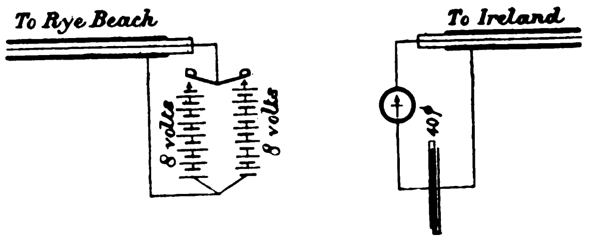
A third cable was then laid from the cable-house across the harbour, and out through the eastern passage in the direction shown on the diagram. It had a total length of 5·8 knots, sheathed up to within half a mile of the sea end. This unsheathed half mile of core terminated in a copper earthplate one yard square, nearly on a line between Thrumcap Rock and Hartland Point. This well-insulated line offered every prospect of securing a good and independent earth by its large terminal plate. When, however, it was joined up at the cable-house with the Irish circuit, in the place of the Irish shore-end sheathing, the interference from the Rye Beach transmission remained as marked as ever.

To determine the nature of this obstinate interference, a series of experiments was made at the cable-house as follows:

All existing connections were for the time dismantled, and only the two cables, the two earth-wires soldered to their respective sheathings, and the core of the third cable, or six-mile earth, were brought up to the testing table.

Fig 1.

Experiment No. 1.



The resistances between these three earth-wire terminals was measured as follows by bridge:

Between Irish sheathing and Rye Beach sheathing ...0·16 ω		All steady.
,, ,, ,, ,, six-mile earth.........65·7 ω		
,, Rye Beach ,, ,, ,, ,, ...65·7 ω		

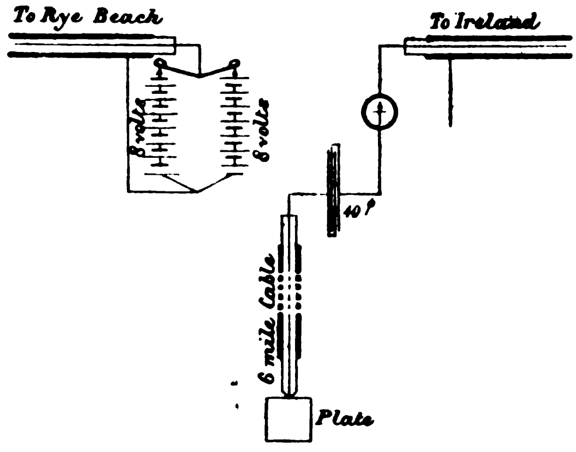
From which the resistance of each sheathing earth connection would, of course, be 0·8 ω, and of the six-mile earth 65·6 ω.

The only apparatus then retained for investigation was a Daniell battery of 14 gravity cells—used with, and sometimes also without, a pole-changer—for exciting disturbance, and a sensitive speaking mirror—used with, and also without, condensers of 40 φ capacity—to render any interference visible.

Experiment 1 (see Fig. 1).—Sending reversals from seven cells into the Rye Beach cable produced vibrations of the spot on the mirror instrument in circuit with the Irish cable, its sheathing, and 40 φ.

Fig 2.

Experiment No. 3.



Experiment 2.—Similarly, sending reversals into the Irish cable, using its sheathing, produced vibrations on the mirror in circuit with the Rye Beach cable condenser and sheathing.

Experiment 3 (see Fig. 2).—Sending reversals into the Rye Beach cable produced vibrations on the mirror in circuit with the Irish cable condenser and six-mile earth.

Experiment 4 (see Fig. 3).—Sending reversals into the Rye Beach cable, using the six-mile earth, produced vibrations on the mirror in circuit with the Irish cable condenser and its own sheathing.

Experiment 5.—Sending reversals into the Irish cable, using the six-mile earth, produced vibrations on the mirror in circuit with the Rye Beach cable condenser and its own sheathing.

Experiment 6.—Sending reversals into the Irish cable, using its own sheathing, produced vibrations on the mirror in circuit with the Rye Beach cable condenser and six-mile earth.

Experiment 7.—Sending reversals on the circuit formed by the six-mile earth, battery, and Rye Beach sheathing, the disturbance on the

* Paper read last night before the Institution of Electrical Engineers.

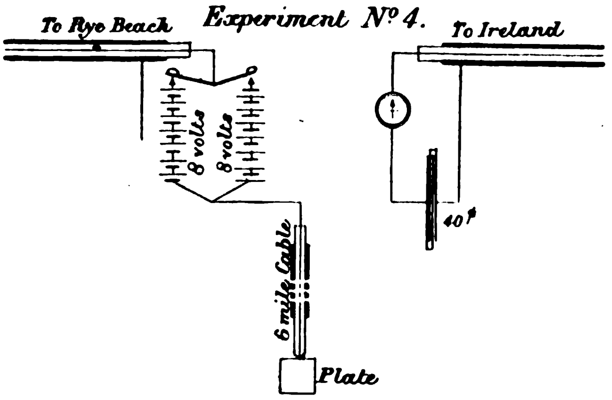
Digitized by Google

mirror in circuit with the Irish cable condenser and sheathing was more decided than in any of the preceding experiments.

Experiment 8.—Similarly, sending reversals on the circuit formed by the six-mile earth, battery, and Irish cable sheathing, the disturbance on the mirror in circuit with the Rye Beach cable condenser and sheathing was equally great.

Experiment 9.—The two last experiments were repeated with the condenser removed and the mirror in direct circuit between cable and sheathing. The continual vibration of the spot made observations difficult; but during periods of comparative quiescence it was soon determined that the disturbance produced by depressing one of the keys was not of a momentary nature only, but consisted of a small deflection, permanent during the whole period of key application, and of direction depending upon the key selected. It was also ascertained that this deflection was not due to any local electro-magnetic action by

Fig 3.
Experiment No 4.

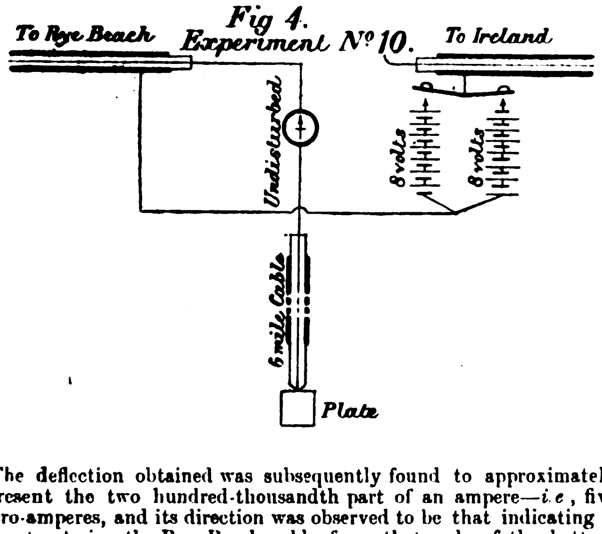


Experiment 10 (see Fig. 4).—On sending reversals between the two cable sheathings in circuit with the battery, no disturbance could be detected on the mirror in circuit with one of the cables and the six-mile earth.

This small steady deflection produced by holding down the key in either of the two cases tried in Experiment 9 was more plainly visible when the mirror was in circuit with the Rye Beach cable, which, besides its shorter length, had no condenser in circuit at the distant station. To obtain some quantitative information regarding the strength of current represented, the 14 cells were connected in series and more careful observations made.

Experiment 11.—Closing the circuit formed by the 14 cells, the six-mile earth, and Irish sheathing, measurements were made of the steady deflection so produced on the mirror joined up with the Rye Beach cable and sheathing.

Fig 4.
Experiment No 10.



The deflection obtained was subsequently found to approximately represent the two hundred-thousandth part of an ampere—*i.e.*, five micro-amperes, and its direction was observed to be that indicating a current entering the Rye Beach cable from that pole of the battery which was connected to the Irish sheathing, reversing when the battery was reversed. Thus, in the figure the copper pole of the battery being shown connected to the sheathing, the deflection represented a current from the copper pole entering the Rye Beach cable through the mirror.

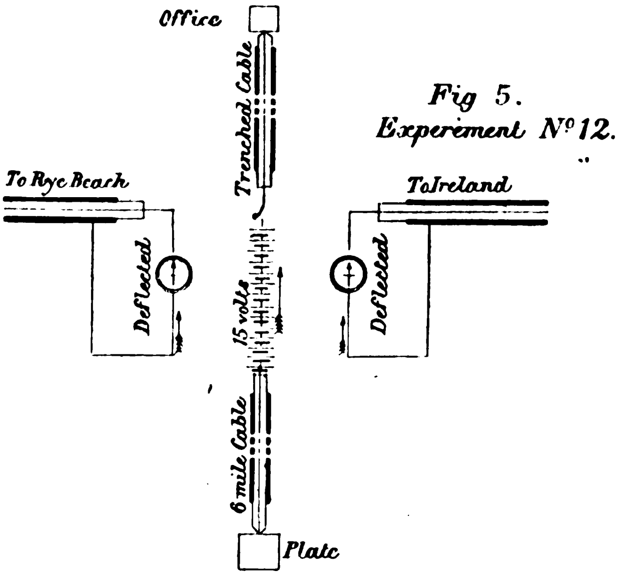
Experiment 12 (see Fig. 5).—The Irish sheathing was replaced in the battery circuit by the water-pipe earth connection at the office through the trenched cable. On depressing the key the mirror showed the same permanent degree of disturbance as before in each cable circuit.

Experiment 13.—This experiment was a repetition of No. 3, with the condenser removed. It was subsequently observed in this case that the disturbance was not permanent during the depression of the battery key, but consisted of a small vibration of the spot at the opening and the closing of the battery circuit.

Experiment 14 (see Fig. 6).—This was carried out at the office, situated in the principal street of the town and nearly opposite to the Western Union Telegraph Office, 50 yards distant. All the Western Union wires are overhead, and the earth connections made for them are the gas and water mains, which, with the telephone lines, form the only metallic connection between the two buildings. With the courteous assistance of the Western Union officials, it was arranged that at a given word by telephone several of their circuits should suddenly be operated, and again, all stopped.

When this was done the effect was distinctly visible upon a mirror in circuit with each cable, the disturbance being greater on the Rye

Fig 5.
Experiment No 12.



Beach line, the earth connections being the cable sheathings through the insulated cables in the trench. Only four known causes could under any conditions produce interference between the two cable circuits, these being, of course, electrostatic induction, electro-magnetic induction, leakage, or bad earth connection in common, and in the absence of evidence, any one or more might produce it, although no reason could be demanded for the operation of any, since cables lie in other parts of the world for greater distances at equal proximity without the least visible interference.

Experiment No. 10, together with the preliminary trials with the trenched cables, showed that the causes were not to be traced locally to these or to the apparatus, and the high insulation of the cables and circuits, together with the fact that the tests were carried out at the cable-house, precluded all possibility of leakage being concerned, so

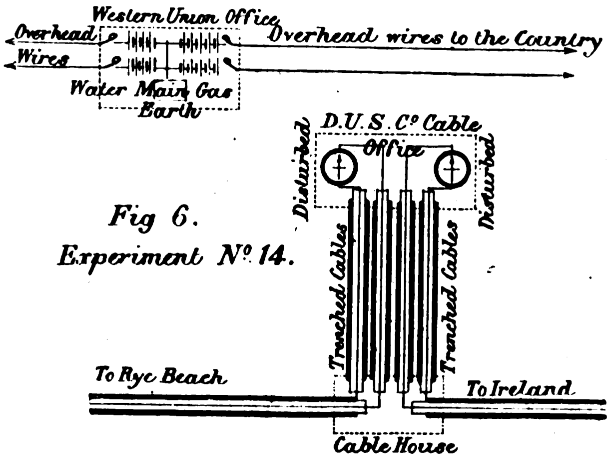


Fig 6.
Experiment No 14.

that the operating causes were thus limited to the two forms of induction and bad earth.

The first six experiments did not directly point in favour of any particular cause, but Nos. 7 and 8 rendered the possibility of electro-magnetic disturbance untenable, since the exciting circuit, except in the cable sheathing itself, took a course, as seen on the map, almost at right angles to the two main cables. They further showed that the interference was such as a deficient earth connection would produce. Experiment No. 9 confirmed this view, since no form of induction could set up the steady deflections observed; and leakage being out of the question, bad earth was the only cause that could produce them. It was further necessary to suppose that not only one but both cable sheathings failed to secure good earth, and that the resistance in their respective earth connections was common to both.

Experiment 11 corroborated this position; and No. 12 did more, for it extended the limits of this bad earth region over the whole water-pipe area of Halifax, as it would have been impossible to obtain interference under those conditions unless the cable sheathings and the town water-pipes formed a common conducting system throughout whose limits imperfect earth connection existed. Finally, the

Digitized by Google

evidence of Experiment 14 followed the same direction, the exciting circuit being in this case the Western Union land lines.

The imputation of bad earth to the gas and water pipe area of a town, and that town a seaport, is sufficiently remarkable; but the presumption of a general earth imperfection in a system of extended water and gas mains, together with the sheathings of three cables running directly into an arm of the sea, may at first sight appear an outrage upon credulity. Due consideration of the experimental evidence renders the conclusion, however, inevitable; and this is tantamount to the assertion that the whole of this system—that is to say, all the land covered by the town, as well as that forming the harbour basin—is composed of substance more or less insulated or insulating.

One of the most interesting features in the geology of Nova Scotia is that the Atlantic seaboard presents an uninterrupted line of Lower Cambrian formation. The relation of this fact to our immediate subject is patent when we remember that these rocks—early in order of geological structure, and said to be almost destitute of organic remains—are here almost entirely composed of argillites, quartzites, and micaceous schists—slates and grits—substances experimentally known to be non-conductors; and according to the published papers of Prof. Honeyman, who has studied the geology of Nova Scotia for many years, no other formations mingle with the Lower Cambrian in the structure of the Halifax basin except the still lower archæan granites, all of which are presumably non-conductors. In fact, the renowned natural advantages of Halifax Harbour are due to the unrelieved presence of these abrupt slaty cliffs that immediately underlie the soil for miles inland.

The question then arises, granting that on the above geological considerations the rocky basin of the harbour and foundation of the city form an insulating crust, or one, at least, interposing a decided amount of resistance between the superficial conducting system and the ocean or earth's mass, is the resistance that can be jointly offered by the three cable sheathings and the whole waterway between the cable-house and open sea of sufficient magnitude to produce the degree of interference observed?

The answer, which seems to be affirmative, strictly demands a computation of the resistance offered by the entire mass of sea-water in the harbour under those conditions. This would be a gigantic problem to solve with any pretence to accordance with nature; but for the purposes of the case such limitations may be admitted as shall greatly simplify the calculation.

The map shows that three channels open upon the inner harbour, one running inland through the narrows, and two passing seawards—the eastern passage, and the main or southern entrance. The inland channel terminates in a bay some miles beyond, and may be considered to be practically insulated with the rest of the basin. The waterway in the shallow and narrow eastern passage will evidently offer a comparatively high resistance compared with that of the main entrance, which, therefore, demands principal attention.

The general mathematical theory of the earth's resistance is given in Schwendler's "Testing Instructions," following the reasoning of Smaasen's theory, published in 1847. It is shown that if a perfectly conducting small spherical electrode of radius r were situated concentrically within a larger hollow perfectly conducting sphere of radius R, and the intervening space filled with a homogeneous substance of specific resistance ρ, the resistance of any elementary spherical shell of radius x, measured from the common centre, would be $\frac{\rho\, dx}{4\pi x^2}$, and hence the total resistance (ω) between the two spherical electrodes would be the integral of this quantity between the limit $x = R$ and $x = r$; whence

$$\omega = \frac{\rho}{4\pi}\left(\frac{1}{r} - \frac{1}{R}\right).$$

If the radius R of the outer electrode be indefinitely increased, the resulting equation becomes

$$\omega = \frac{\rho}{4\pi r},$$

which represents the resistance of an unlimited medium of resistance ρ to a current passing from a sphere of radius r to its ultimate confines. Similarly, a second small spherical electrode of radius r_1 would offer under the same circumstances a resistance

$$\omega_1 = \frac{\rho}{4\pi r_1}$$

and if these two small spherical electrodes were placed so far apart in the medium that their direct influence on each other's lines of current-flow would be very small, the resistance between them would be

$$\omega + \omega_1 = \frac{\rho}{4\pi}\left(\frac{1}{r} + \frac{1}{r_1}\right)$$

—a result equivalent to the statement that almost all the lines of current-flow issuing from the surface of each electrode would unite with least opposition at indefinitely great distances, and after indefinite diffusion throughout the medium.

If the system were then symmetrically divided by an unlimited insulating plane, the resistance (Ω) between the hemispheres on one side of the plane would be double the above, or

$$\Omega = \rho\left(\frac{1}{c} + \frac{1}{c_1}\right),$$

where c and c_1 are the circumferences of the two hemispheres.

This would then be the resistance between two hemispherical electrodes imbedded in the bounding plane surface of an indefinitely extending homogeneous medium; and if the electrodes were not hemispheres, but vertical plates imbedding active surfaces (s and s_1), the above formula would approximately apply, if c and c_1 be the circumferences of equivalent hemispheres exposing those areas respectively, and the transformed equation would be

$$\Omega = \frac{\rho}{\sqrt{2\pi}}\left(\frac{1}{\sqrt{s}} + \frac{1}{\sqrt{s_1}}\right)$$

—an equation independent of the distance between the plates.

Similar results are obtained and published by MM. Mascart and Joubert by separate reasoning. The formula applies to the earth's resistance in a telegraphic circuit, on the assumption that our planet has a practical uniform conductivity, and forms practically an indefinitely extended medium.

In the absence of experimental evidence it would be difficult to say how far the variable conductivity of the earth's mass would affect the application of this formula. The conductivity of the material composing the earth's crust probably varies considerably in different localities, and is generally not the same as that of the ocean, for example. It might even be assumed that the resistance of the primary rocks is so great as to limit the conducting area almost entirely to the superincumbent stratified formations.

In that case the earth's telegraphic resistance would be more nearly comparable to the resistance between two small distant electrodes imbedded in the surface of an indefinitely extended sheet of uniform thickness and conductivity. On this supposition, let d be the depth of the earth's conducting crust, assumed to be uniform, then the resistance, Ω (*vide* appendix), between two earth-plates of active surfaces (s and s_1) would be, approximately,

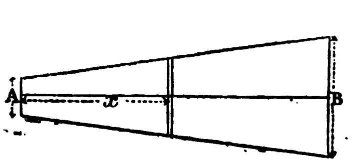
$$\Omega = \frac{\rho}{\sqrt{2\pi}}\left(\frac{1}{\sqrt{s}} + \frac{1}{\sqrt{s_1}}\right) + \frac{\rho}{\pi d}\log._\epsilon\left(\frac{4\,D}{d}\right).$$

This equation is the same as that of Schwendler last stated, but with the addition of a second term involving D, the distance between the plates; so that on this theory the earth's resistance would increase with the length of the circuit. If submarine cables were sufficiently well insulated, it would be possible to ascertain which of these two theories is nearer to the truth, by measuring the conductor resistances of cables which are laid in duplicate or triplicate between two stations; the difference between the resistance of any pair looped, and the sum of their separate resistances employing the earth circuit, giving, of course, double the earth's resistance between the terminals. It is, however, impossible to decide from present experimental evidence in this way, since not only does the difficulty of accurately measuring these quantities probably increase with the square of the length of cable, owing to leakage and other causes, but also because this second term of the last equation whose existence is in question must in all cases be very small.

Generally speaking, therefore, the experimental evidence may be said to establish the results given by Schwendler's formula—namely, that when the earth-plates are separated by any distance great compared with their dimensions, the resistance varies with their active area, and is independent of their distance.

Schwendler gives an estimated superior limit of the specific resistance of the earth in India as 3,300 ω, or about 100 times that of saturated zinc sulphate solution at 10deg. C.

Returning to the resistance offered by the waterway in the main entrance of Halifax Harbour, we may suppose a current to be flowing seawards through it, and the cable sheathings from the cable-house. The lines of flow will permeate its whole area, and the equipotential surfaces may be supposed to form across it in successive curves. These surfaces will be practically vertical, and a position has to be assumed for the ultimate one representing the zero-potential, or the surface that may be considered to mark the limit of perfect earth connection. Theoretically, of course, this limit would be far out in the ocean; but it may be arbitrarily assumed that a vertical plane, shown on the map by a dotted line, connecting the Thrumcap with the Mars Rock buoy represents this boundary, and that the resistance to earth of the ocean mass outside this plane is altogether negligible. The two other dotted lines converging from this base up to the cable-house—one skirting Sandwich Point, and the other running over Maugher Beach—are intended to represent what may be considered the simple boundaries of an equivalent waterway equal in conductivity to the actual one. The average depth may be taken as 14 fathoms. We have, on this supposition, a mass of sea-water resembling a wedge with a blunt point, the breadth of the base being 1·2 knots; the breadth at the apex, say 5 metres; the length measured perpendicularly to the base, 4 knots; and the depth, 14 fathoms. Strictly speaking, the equipotential surfaces of flow will be curves convex to the ocean; but the error introduced will not be great if we consider them as planes parallel to the base, or zero surface. Since the fall of potential will take place with equal rapidity through the water and through the sheathings, the resistance of the latter may be taken into account later and independently. The



resistance of any elementary lamina of thickness dx, distant x from the cable-house, will be $\frac{\rho\, dx}{h\,(ax + b)}$, where ρ is the specific resistance of the water, h the depth, while a and b are constants; so that the tota resistance between the two ends is

$$R = \frac{\rho}{ah}\log._\epsilon\frac{B}{A},$$

Digitized by Google

where B and A are the breadths at the base and apex. In this case

$$a=\frac{1\cdot 2}{4\cdot 0}=0\cdot 3\ ;$$

$$h=14\times 6\times 30\cdot 5=2{,}560\ ;$$

$$\frac{B}{A}=\frac{185{,}000\times 4\cdot 2}{500}=1{,}550\ ;$$

$$\rho=31.$$

The specific resistance of a saline solution of density 1·027 has been observed experimentally to be about 31 ω at 5deg. C.

With these data,

$$R=\frac{31\times 2\cdot 72\times 3\cdot 19}{0\cdot 3\times 2{,}560}$$

$$=0\cdot 35\ \omega,$$

about one-third of an ohm, equivalent to a conductivity of .... 2·9 mhos.

Compared with this, the conductivity of the eastern passage channel may be estimated at about one-fourth, or .... 0·7 mho.

The conductivity of the two cable sheathings, each consisting of 10 No. 6 wires, and length 4·2 knots, would be 20 × 0·020 .... = 0·4 mho.

And, finally, the conductivity of 7 knots of cable sheathing in the eastern passage, 10 × 0 012............ = 0·1 mho.

Total conductivity .... 4·1 mhos,

equivalent to a joint resistance of 0·24 ω. So that if the above reckoning is sufficiently fair, the resistance between the cable-house and the ocean is about a quarter of an ohm.

The resistance actually offered can be estimated from the data of Experiment 11, as follows:

The E.M.F. in the exciting circuit was about 15 volts ; the resistance, 66 ω in the cable and earths, and 24 in the battery—total, 90 ω. In the Rye Beach circuit the resistances at the time were, approximately :

Observing mirror............	2,000 ω
Cable conductor	5,800
Relay at Rye Beach............	1,000
Total............	8,800 ω

Since the interference current observed in this circuit was, as already mentioned, 5×10^{-6} amperes, the E.M.F. impressed upon the cable due to interference was

$$5\times 10^{-6}\times 8\cdot 8\times 10^{3}=0\cdot 044 \text{ volts ;}$$

and consequently, if x be the required resistance of the general earth connection,

$$x:90::0\cdot 044:15,$$

or $$x=0\cdot 26\ \omega,$$

or an actual resistance of a quarter of an ohm. The agreement between the actual and measured values is really much closer than the accuracy of either determination would warrant.

The only experimental results still left unaccounted for are those of Nos. 3, 4, 5, and 6, in all of which the six-mile earth was used either in the exciting or observing circuit ; and since Experiment 13 proved that this earth-plate was outside the limits of the semi-insulated basin, as might be expected from its position on the map, it would be impossible to account for the interference in those cases on the score of a common imperfect earth. Reflection shows, however, that the interference observed would be an indirect necessary consequence of the imperfect earth, since the six-mile earth, when connected to either main circuit, forms a cable-loop of, say, 10 knots within the limits of the semi-insulated basin, and a slight variation in the potential of the basin is calculated to produce a considerable electrostatic effect on the cable. It has, in fact, been found experimentally that when 1,000ft. of insulated cable core (of similar capacity to that of the cables at Halifax) are coiled in an insulated tank and left in communication with the earth through a mirror instrument, the electrostatic disturbance of the mirror is about equal to that observed in these experiments (3—6) when the potential of the tank is altered by 0·2 volt. The total charge passing through the mirror in Experiments 3 and 6 would be the resultant effect of the whole system of harbour potential variation on the four knots of cable under observation, except in so far as the capacity of the cable seawards would modify the influence. In Experiments 4 and 5 the interference would, on the other hand, be due to electrostatic charge entering the observing circuit owing to the variation in the harbour potential, electrostatically produced by the loop of exciting cable traversing it. An external average variation of 0·01 volt in the potential of the basin would suffice to account for the degree of interference observed ; and this amount of variation, it is evident, the conditions amply supply. Experiment 13, contrasted with Nos. 9 and 11, showed that the interference observed in cases 3, 4, 5, and 6 was of an electrostatic nature.

The sensitiveness of a cable to external electrostatic influence can be shown experimentally by joining up a mirror galvanometer in circuit with 100 miles of cable and earth. If the distant end be sealed, and laid for two or three feet in an insulated joint trough filled with water, the potential of which is capable of being varied suddenly through 100 volts (from +50 to −50), the effect is immediately visible on the galvanometer ; and, in fact, simple signals have been transmitted in this way from ship to shore through the coatings of a joint.

The hypothesis of an insulated or semi-insulated basin, therefore, satisfactorily explains all the phenomena observed. It accounts, first, for the meteorological disturbances which are observed on the cables, since any alteration of the charge or position of electrified clouds in the vicinity of the harbour may affect the distribution of charge in the cable to an extent that would not be possible if the harbour were in more perfect electrical communication with the ocean or earth's mass ; and all the phenomena experimentally observed can be traced either to the direct or indirect effects of this imperfect earth connection—directly by conduction, indirectly by induction.

Assuming, then, that the Lower Cambrian rocks effectively insulate the Halifax basin, it is necessary to suppose that the same effect would be produced at any landing-place on the Atlantic shore of Nova Scotia, where these rocks so generally prevail. This is also corroborated by the fact that previously, at Torbay, some difficulty of the same kind appeared when attempts were originally made to utilise an ordinary earth connection for an overhead Morse circuit. The interference with the cables thus set up rendered a special earth necessary for the land line in the bay. The fact that no interference was visible between the cables themselves is accounted for by the open landing-place and absence of any such basin as Halifax Harbour presents.

In Mr. James Graves's paper on earth vibrations, already alluded to, mention is made of the slaty character of the rock in the neighbourhood of the station, and so favours the supposition that the interference there observed was due to the same causes.

It is said that in the Lake Superior region of the United States great difficulty has occasionally been found in obtaining efficient earth, even when no local cause for the deficiency has been apparent. I am indebted to Prof. Moses G. Farmer for the facts of a case which came under his notice, where an earth connection, apparently good and well situated, was found useless, and measurement showed that its resistance to earth was 12,000ω. I also owe to him the information that interference due to imperfect earth was found in 1869 at St. Pierre Miquelon, the Morse signals on the St. Pierre Placentia circuit affecting the Atlantic cable to Brest, and that special measures had to be taken to effect better earth connection.

Generalising from these facts, it would seem that there may be difficulty in obtaining good earth at cable stations opened on a shore of primary or metamorphic rock, and that permanent interference beyond remedy by earth connection is possible between cables landed in a basin of such formation ; so that if this statement receive confirmation at the hands of the members of this Institution it will be evident that a due regard will be given to geological conditions by electrical engineers among the many incidental considerations that determine their selection of a cable's landing place.

Appendix.

On the resistance between two electrodes of active surface (s and s_1) imbedded in the surface of an indefinitely extended homogeneous medium of specific resistance ρ comprised between two unlimited parallel planes separated by a perpendicular distance d, the distance between the electrodes being represented by D.

Let r and r_1 be the radii of the equivalent hemispheres exposing surfaces of s and s_1 respectively. Then, if an infinitely thin perfectly conducting hemispherical shell of radius d concentrically surrounds each of these electrodes, these shells will touch the opposite bounding plane of the medium, and the resistance between them and their included electrodes will be

$$\frac{\rho}{2\pi}\left(\frac{1}{r}-\frac{1}{d}\right) \text{ and } \frac{\rho}{2\pi}\left(\frac{1}{r_1}-\frac{1}{d}\right) \text{ respectively.}$$

If D be large compared with d, these two shells may be approximately considered as two parallel cylinders of radius $\frac{d}{2}$ traversing the medium at right angles to the bounding planes, and their surface potentials may be written (see Mascart and Joubert's "Electricity and Magnetism," vol. i., p. 205)—

$$V_1=\text{constant}-\frac{c\rho}{2\pi d}\log.\epsilon\left(\frac{\frac{d}{2}}{D}\right);$$

$$V_2=\text{constant}-\frac{c\rho}{2\pi d}\log.\epsilon\left(\frac{D}{\frac{d}{2}}\right),$$

where V_1 and V_2 are the potentials and c the strength of current.

$$\therefore V_1-V_2=\frac{c}{2\pi d}\left(\log.\frac{2D}{d}-\log.\frac{d}{2D}\right),$$

$$\therefore \text{Resistance}=\frac{\rho}{\pi d}\log.\epsilon\left(\frac{4D}{d}\right);$$

so that the total resistance,

$$\Omega=\frac{\rho}{2\pi}\left(\frac{1}{r}+\frac{1}{r_1}-\frac{2}{d}\right)+\frac{\rho}{\pi d}\log.\epsilon\left(\frac{4D}{d}\right);$$

and since d is large,

$$\Omega=\frac{\rho}{\sqrt{2\pi}}\left(\frac{1}{\sqrt{s}}+\frac{1}{\sqrt{s_1}}\right)+\frac{\rho}{\pi d}\log.\epsilon\left(\frac{4D}{d}\right),$$

approximately.

Papers.—At the Institution of Electrical Engineers next Thursday, Prof. Forbes "On Some Electric Lighting Central Stations in Europe and their Lessons." At the Physical Society to-morrow, at 3 p.m., in the Lecture-room, Science and Art Department, Prof. Ayrton "On Notes on Electrical Measuring Instruments," exhibiting his new instrument.

Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

'SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations ; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months		6 months		12 months.
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places	4s. 10d.	...	9s. 8d.	...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed " Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of Mr. E. Graves, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. Wollaston, M.D., F.R.S., *and* Sir Humphry Davy, F.R.S. *The portraits of* Prof. D. E. Hughes, F.R.S., *and of* Dr. J. Hopkinson, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

WINNING AND LOSING.

The result of litigation generally ends in the jubilation of one side, and a corresponding sorrowing of the other. It is seldom that we can write as we did of the original judgment in the Edison-Swan *v.* Holland case, "Honours divided," and perhaps it is as well that it should be so. Neither side was satisfied with a half win. Elsewhere we give the full text of the judgment in the appeal, and in this judgment the three judges engaged concurred. There is little hope that the litigation is ended, and the last information about it is that already notice has been given that it is to be carried to the House of Lords. Then, and not till then, it is to be feared, will the parties stop, and not even then—but they cannot go farther.

Nothing that we can say will influence the parties in this suit, for whoever heard of litigants accepting advice tendered by unbiassed outsiders—onlookers who have nothing to gain and nothing to lose whatever the result may be. Pity 'tis 'tis true. During the "eighties," electrical industries have advanced by leaps and bounds, but what about litigation upon electrical matters? Money has been lost and won in electrical speculations; but how about "dividends" paid to shareholders? The legal profession is a glorious profession, and we are inclined to think that the money paid to that profession, divergent from the shareholders' pockets, is out of all proportion to that which has gone into the shareholders' pockets. This golden stream seems likely to be so diverged till the mass of patents taken out during the last ten years expires by flux of time. There are many ways of looking at the question of patents, and it would take a volume to adequately discuss one half of them. Our purpose will be served by putting clearly forward the views which seem to permeate the profession, some members taking the one view, some the opposite.

The question in dispute is the validity of the Edison-Swan combination patents. It is a fact admitted by everyone that Swan and Edison were simultaneously working out the question of practical incandescent lamps at about the same time. Swan had made lamps, but they were looked upon as imperfect, as was shown by letters passing between Swan and Stearn. Edison about the same time obtained a patent for a lamp which the one side says is not practical, and has never been commercially made. The judges hold that the lamp of the patent is practical, and the validity of the patent has nothing to do with the lamp being made commercially. That improvements were to be expected directly the manufacture on a commercial scale commenced, was but natural. Such improvements were made, and the commercial lamps are the result of those improvements. Given the original

Digitized by Google

more or less crude but practical idea, and hundreds of minds turned at once to its study, producing a crop of patented improvements, and which the patentees expect the law courts to proclaim valid patents. The law courts refuse to do anything of the kind, and say in effect, None of these recent improvements are inventions to be covered by a patent, and the patentees would never, without the aid of the master idea in the master patent, have invented anything of the kind. "It is easy when you know the way." It is easy to improve somebody else's invention, but it is difficult to invent. That is, in reality, the crux. As will be inferred from our remarks above, the strongest objection against the validity of the Edison-Swan patents is in the direction tending to show they are improvements of prior inventions, and not new inventions. The judges have not been convinced that this is so—hence their decision, which says, though not in so many words, that Edison did really invent the practical filament. We take it that for the moment nothing more is to be said. An official of the Great Western Railway once remarked to a person that was complaining, "The best you can do is to grin and bear it." The advice is sound in many cases, and applies to further action *re* the House of Lords. Had this appeal gone otherwise, there would have been legitimate doubt as to the result of further action. Now we feel convinced there can be none. Time after time the Edison-Swan combination has been successful, and depend upon it that fact will have considerably more weight than that they were once only partly successful. We know that these views are not held by many who have carefully considered the matter, and whose opinions are generally to be received with the greatest respect.

There is another grievance real enough from one point of view, yet it must be considered as purely sentimental. It refers to the great benefits that would accrue to the industry generally if there were no monopoly. No doubt the benefits that would accrue are, as we say, real enough, but there would have been no industry if there had been no invention—that is, if there had been no monopoly. It is better to have an industry with a monopoly rather than no industry and no monopoly. Is it impossible for the litigants to shake hands? Suppose the Edison-Swan combination feel certain of the final result, will it not pay better in the long run to amicably arrange for royalties and pay half the costs up to the present time, than to continue to take money from the industry that might be used with great advantage and put it into the pockets of lawyers, where it will give no benefit to the electrical industry? The difficulty is to stop at any stage in legal proceedings after they have once commenced, and which ought never to have commenced. At least fifty thousand pounds have been diverted from shareholders' capital to legal expenditure—an amount preposterously large in comparison to the benefit received, whatever the final result may be.

CORRESPONDENCE.

ELECTRIC LIGHTING OF HARROW.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—Mr. Crompton, last night, in the statements which he promulgated to a meeting of the Local Board and ratepayers of Harrow, will doubtless have much astonished those who either heard or read his paper delivered at the Institution of Electrical Engineers last year, and his reply to Mr. Kapp's paper, read before the same body. Mr. Crompton now poses as the advocate of a transformer system, and he now admits that the figures for which he was so much taken to task less than a year ago are entirely wrong. Mr. Crompton, after having stated that a small installation costs more in proportion than a large one of similar nature, proceeded to inform his hearers that an installation of 3,000 lights would cost but £6,000, with 1,500 yards of main, of which 1,000 were underground; and upon exception being taken to his figures, he stated that the conditions of laying mains in London, as provided for in his former paper, are quite different to the laying of mains in the country. Now, excluding the cost of mains entirely from Mr. Crompton's estimate, and that of buildings, which are necessarily more expensive in London, the following will be found a correct statement of the figures of yesterday and of last year.

For a 3,000-light plant, Mr. Crompton made out figures as follows at the meeting held yesterday:

Engines	£1,560
Dynamos	1,800
Switchboard and measuring instruments...	100
Transformers	850
	£4,310

Last year, Mr. Crompton estimated the cost of a 10,000 light or 600 kilowatt plant at:

Dynamos and exciters 865 kilowatts, including spare sets, divided as convenient	£5,540
Motive power—*i.e.*, engines, boilers, steam and feed connections, belts, etc.—at £8. 12s. per h.p.	12,470
500 transformers—*i.e.*, one of every pair of houses at £15 each	7,500
Regulating gear	500
	£26,010

that is to say, taking in round numbers the 10,000-light plant at £26,000 and the 3,000-light plant at £4,300, the former plant at the same price as the latter would only cost about £14,400, or, say, 60 per cent. of the cost, as estimated in Mr. Crompton's paper before the Society of Telegraph Engineers. As Mr. Crompton's figures will, we feel sure, give much encouragement to the transformer party (among whom we beg to subscribe ourselves), we do not care to criticise them for fear of scaring such an influential convert. It will be recollected that Mr. Crompton, in his reply to Messrs. Kapp and Mackenzie last year, made mention of the waste which occurred by running triple expansion engines with alternating current dynamos and transformers on light loads, which were absolutely necessary at full load to reach the highest peak of any ordinary load diagram. Mr. Crompton, in reply to a query last night, said there was a difference, in that in the Harrow schoolhouses the peak would be a plateau. Mr. Crompton did not seem to acknowledge the fact that a simultaneous lighting of 2,500 lamps at 6.45, when the boys come in from school, would have exactly the same effect as a peak, and the similarly simultaneous extinction of the lamps later in the evening would give a diagram rather like a factory chimney, and, according to Mr. Crompton's old theory, be even more wasteful in the hours of lightest load than the gradually ascending and descending peaks of a London diagram.

Digitized by Google

It seems to us that the whole blame attaching to Mr. Crompton's fiasco lies with Mr. Hayward, who, as will be seen from the report of the meeting, either wilfully or unintentionally forgot the fact of the appointment of a special committee on the subject, a matter with which, as chairman of the Board, and present when the committee was appointed, he ought to have been perfectly acquainted. We reserve our further remarks to another issue of your journal.—Yours, etc., W. F. AND F. TAYLOR.

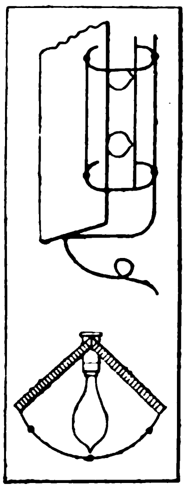
Harrow, February 20, 1889.

[As a full report of the meeting is given elsewhere in our columns, our readers will be able to form their own conclusions upon the questions above mentioned.—ED. *E. E.*]

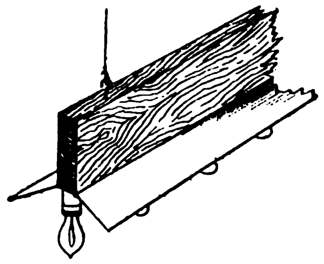
ELECTRIC LIGHTING OF THEATRES.—IV.

AVENUE THEATRE.

The installation at the Avenue Theatre, Northumberland-avenue, is one of the most recent, and, as might be expected, one of the most conveniently arranged in London. This theatre is one of those drawing its supply of current from an outside source, connection in this case having been made, by means of underground mains in bitumen troughing, along Whitehall-place, to the Metropolitan Electric Supply Company's station at Whitehall Court, where the low-tension direct current system is in force. The interior arrangements have been carried out by Messrs. B. Verity and Sons, Covent Garden, and they have produced a very compact, convenient, and satisfactory theatre installation.



Side Lights.



Battens.

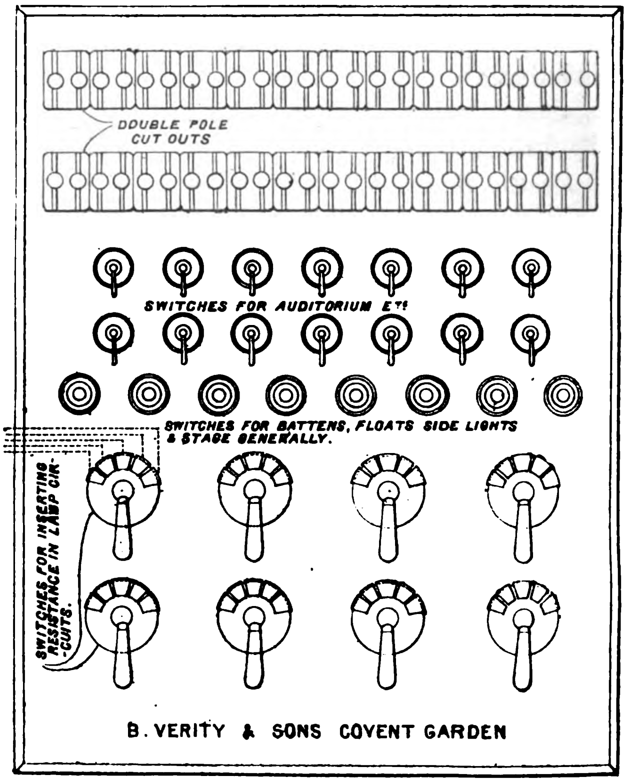
The whole of the theatre is now lighted electrically, both before and behind the scenes and in all the dressing-rooms and passages, the sunlight alone in the centre of the auditorium being excepted; here gas is still used for centre light and for purposes of ventilation. The following is a list of the lamps installed, which will serve to give a very good idea of the distribution of light necessary in a theatre:

Stage.—Battens, 200, in four sets; footlights, 50; proscenium, 30, in two sets; sidelights, 86; doors to stage, 2—total for stage, 368.

Auditorium.—Stalls entrances, 3; stalls, 4; pit, 5; pit entrance, 4; gallery, 18, gallery entrance and staircase, 7; dress circle, 10; box office and main entrance, 11; front staircase, 15; private office 3.

Basement.—Corridors and stairs to stage, 11; dressing-rooms, prompt side, 14; dressing-rooms, O.P., 14; dressing-rooms and passages under stage, 14—total in front of stage, 123. Total number of lamps, 491.

The lamps are all Edison-Swan lamps of 16 c.p., mounted mostly in Edison sockets. All the stage lamps are arranged to be raised or lowered in brilliancy for scenic effects. The battens—the rows of lights which swing across the top of the stage to illuminate the scenes—are arranged on swinging boards, which can be very easily raised or lowered in height by the scene-shifter, by means of cords and pulleys. The method adopted for these is neat and simple. A long plank is suspended edgewise, and a series of lamp sockets are screwed to the lower edge of this plank, allowing the lamps when fitted to hang down with unimpeded light. Each batten has a long broad strip of bright tin plate fastened to it at the back of the sockets, and this forms a cheap and very efficient reflector, giving a greatly increased light from the lamps upon the scenes. The sidelights are also arranged to be movable, and are mounted on a long frame made of two pieces of wood joined at right angles, and mounted with a series of lamp sockets. Stout wire protectors are fixed all the way down on each of these to prevent the lamps being knocked accidentally, and each set of sidelights is furnished with a flexible cable, ending in a floor-plug as illustrated, which can immediately be inserted into a hole in the stage floor behind the scenes to make electrical connection. These sidelights are hung upon suitable pegs at the side of the stage, and both these and the battens can be far more easily shifted than the rows of gas-jets hitherto used.



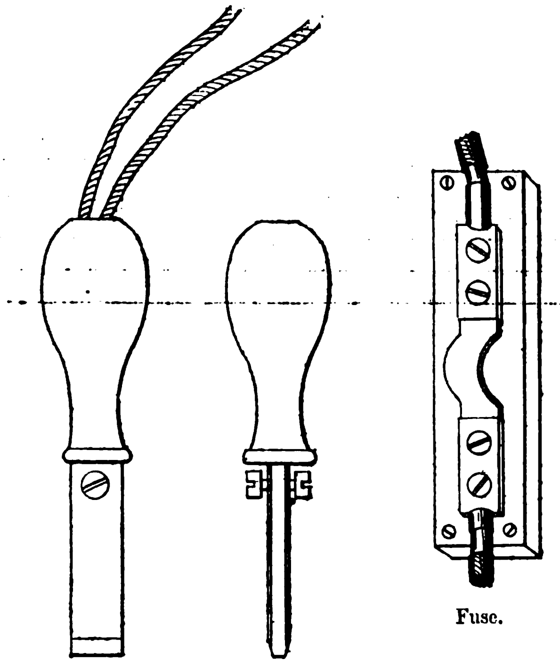
Switchboard at the Avenue Theatre.

The switchboard is very conveniently arranged beside the prompter's box, just inside the side scene. The whole of the switches for the theatre are brought to this one switchboard, and the management of the light is under control from this point. The so-called "gasman" can stand at the prompter's box in full view of the scenery, and can from this position, within reach of his hand, turn in and out, or raise and lower, any of the lights of the theatre. The arrangement of this switchboard is seen in the accompanying diagram. Large switches with multiple contact are arranged for those lights requiring to be varied in brilliancy, and these are connected with an iron wire resistance, which is arranged in a frame on the passage wall immediately below the switchboard. Two rows of Verity's small sudden-break lever switches, with a row of larger switches of a similar kind below as shown, are used to control the various circuits of the auditorium. Double pole fuses of the Edison screw socket type are used, and the whole of these, to control all the branches, are fixed in two rows, as shown on the switchboard above the switches.

Solid double pole main fuses are placed alongside the switchboard to control the main circuit. The fusible metal for these is a special alloy obtained from New York. The mains coming from the street are Callender's cable. The interior mains, branches, and wires are of Henley's manufacture throughout. The fittings are simple, tasteful, and decorative, all made by Messrs. B. Verity and

Digitized by Google

Sons. The installation as a whole is thoroughly satisfactory, so much so that the managers made Messrs. Verity a present of a bonus of £20 over the contract on the completion of the installation, a circumstance which is a



Fuse.

Stage Plug

little unusual, and which we have the greatest pleasure to record.

ADVANTAGES.

We had some conversation with the manager, Mr. H. Watkin, upon the question of the adaptation of the light for theatres and its general advantages. He regards the light as admirably suited to the purposes of a theatre. It is clean, extremely convenient, and perfectly under control; they have a sensible reduction in the insurance; the cost of supply is less than that of gas, and the breakages of the lamps bring it to about the same amount.

The actors speak very favourably of the difference of temperature perceptible upon the stage. They often used to come down to the dressing-room bathed in perspiration from the heat of the footlights, and now are as cool and comfortable as possible.

ALTERNATE CURRENT MACHINERY.*

BY GISBERT KAPP, A.M.I.C.E.

The theory of alternate-current machines, as given in modern text-books, was based upon the assumption that the currents were generated in wire coils, the magnetic induction through which underwent periodical changes according to a simple sine function. A machine of this character would be represented, in its most elementary form, by a coil of insulated wire revolving round an axis in its own plane, with uniform velocity in a uniform magnetic field, the axis of rotation being at right angles to the lines of the field. The E.M.F. at any moment was

$$e = 2 \pi n z \frac{\tau}{2} \sin \alpha,$$

where n was the frequency (number of complete periods per second), τ was the number of wires in both branches A and B of the coil collectively, z was the total induction through the coil when the latter stood at right angles to the lines of force, and α was the angle between this position and the position at which the E.M.F., e, was generated. The mean E.M.F. was

$$e = \frac{\pi}{\sqrt{2}} n z \tau.$$

It was convenient to compare this value with that representing the E.M.F. of a direct-current machine having the same field and external number of wires, τ (but equally distributed) on the armature. The E.M.F. of such a machine was given by the product $z \tau \frac{N}{60}$, where N, the number of revolutions per minute, might obviously be replaced by $60n$ when the machine had two poles, because in this case frequency and number of revolutions per second were identical. The ratio between the E.M.F.'s of the two machines remained the same, $\frac{\pi}{\sqrt{2}}$.

Alternators as now constructed had more than one pair of poles, which were set in a circle, and were so arranged that the coils of the armature swept past them. As the interpolar space was always very small, the density of lines, emerging from or entering the polar-surfaces, might be taken as fairly uniform over the extent of these surfaces, and it became thus possible to determine for every shape of coil the configuration of polar surface which would produce that variation in the induction which corresponded to the simple sine function. Poles of this shape were, however, not used in practice; the poles were either trapezoidal, circular, or rectangular. In the Mordey alternator the poles had a trapezoidal face, and those succeeding each other on the same side of the armature were of the same sign, and were placed in line with those of opposite sign on the other side of the armature. Thus along the mean pitch-line, uniform fields alternated with spaces in which there was no induction. The E.M.F. of this arrangement was

$$e = 2 n z \tau.$$

The type of field most commonly used in modern alternators was, however, one in which N and S poles succeeded each other around the armature, and the portion of the armature not embraced by the poles might be taken as equal to that embraced. The E.M.F. of this arrangement was $$e = \frac{4}{\sqrt{2}} n z \tau$$

These results referred to machines in which the active wires on the armature were concentrated into single lines. This was, of course, impossible in practice; the wire coils on the armature, whether this contained iron or not, must occupy a considerable space, and this circumstance would, generally speaking, cause the E.M.F. obtainable, with the different forms of fields considered, to be lower than the values given. The reason for this reduction was that with a wide coil all the turns were not equally and simultaneously influenced by the field, and in certain positions the action was differential. The calculation of the effective mean E.M.F. for the configuration of field and armature-coils presented no special difficulty, though for certain complicated forms the operation was somewhat laborious.

The E.M.F. of an alternator could be expressed as the product of the E.M.F. of a direct-current machine, having the same dimensions and weight, and a certain coefficient depending on the configuration of the field-magnets and armature-coils. The winding and other constructive data of an alternator being known, it was only necessary to find this coefficient, in order to determine the E.M.F., by reference to the E.M.F. which would be produced by the same machine if the armature-coils were connected in such a way as to give a continuous current. The E.M.F. in volts of an ordinary dynamo was given by the formula: $e = z \tau \mathrm{N}\, 10^{-6}$,

where z represented the total induction in English lines of force (each equal to 6,000 C.G.S. lines), τ the total number of active wires counted all round the armature, and N the speed in revolutions per minute. If the machine was multipolar, and if the different armature circuits were arranged in series, the expression for e must be multiplied by p, the number of pairs of poles in the field. Let k be the coefficient which expressed the ratio between the E.M.F.'s of the alternate and continuous-current machines, then the formula for the former was $e = k p z \tau \mathrm{N}\, 10^{-6}$.

The following table gave the value for k for different cases, all referring to poles of rectangular shape and coils in which the active wires were straight:

1. Width of poles equal to pitch, toothed armature, and winding concentrated in the recesses .... $k = 2{\cdot}000$
2. Width of poles equal to pitch, smooth armature, and winding spread over the whole surface .... $k = 1{\cdot}160$
3. Width of poles equal to pitch, smooth armature and winding covering only one-half the surface............ $k = 1{\cdot}635$
4. Width of poles equal to one-half the pitch, smooth armature and winding spread over the whole surface.. $k = 1{\cdot}635$
5. Width of poles equal to half the pitch, smooth armature and winding covering only one-half the surface... $k = 2{\cdot}300$
6. Width of poles equal to one-third the pitch, smooth armature and winding covering only one-third of the surface .... $k = 2{\cdot}830$

According to the ordinary sine formula the coefficient was $k = 2{\cdot}220$; and this agreed fairly well with case 5, which was most frequently met with in practice. The formula for e pre-supposed the knowledge of the total induction, z, which depended upon the shape and size of the field-magnets, their arrangement, the amount of iron in the armature, the interpolar space, and the exciting power. This subject had been very fully treated by Drs. J. and E. Hopkinson, and the author had also dealt with it. These methods had subsequently been improved by the introduction of certain terms due to Prof. Forbes, by means of which the magnetic leakage could be more accurately ascertained. With the knowledge of the total induction, z, and the coefficient, k, it was thus possible to determine the relation between exciting power and E.M.F. of any given alternator. The effect of self-induction was to produce an E.M.F., the phase of which was at right angles to that of the current; and the E.M.F. available for doing work in the circuit was the resultant of the induced E.M.F. and that due to self-induction. The author then described some graphic methods by which the problem could be treated in a simple and easily understood manner.

In alternators used for parallel distribution, the object aimed at was generally to keep the terminal pressure constant for all currents, and this could be attained by working with a constant field and suitably varying the speed, or by maintaining a constant speed and adjusting the exciting current so as to suitably vary the E.M.F. The latter plan must be adopted if several machines were worked in parallel; and in this case the graphic method might be used to determine the limits between which the exciting current must be varied to keep the terminal E.M.F. constant for all loads, from no current to

* Paper read before the Institution of Civil Engineers, Feb. 19.

Digitized by Google

the greatest current, the armature was intended to pass. The mean induced E.M.F., e, was found by the above formula, and its maximum value was obviously

$$E_1 = \sqrt{2}\,e.$$

The maximum value of the E.M.F. of self-induction was given by

$$E_s = 2\pi n L I,$$

where L was the coefficient of self-induction, which could be determined by various well-known methods; or by running the armature in a constant field, and measuring the terminal E.M.F. with and without a current passing through the armature. The E.M.F. lost in resistance was simply the product of the current, I, and the resistance, R, of the armature. With the knowledge of these quantities it was easy to determine the strength of field required for any current.

The problem of parallel working was of the greatest importance for central stations, as only by such an arrangement of machines was it possible to ensure absolute continuity of the service and the greatest economy at all times. Alternate-current distribution should, if possible, be carried on in the same simple manner as direct-current distribution—that was to say, the number of machines at work should correspond as nearly as possible to the output at any time; the addition or withdrawal of machines should not even momentarily interrupt the supply of current to any part of the system of distribution. These conditions, it would easily be seen, could only be fulfilled if the machines were capable of working in parallel, and the problem might be stated somewhat in this fashion: Given an alternator, with excited field and running at a proper speed, and a pair of terminals from which any desired strength of current could be obtained at a constant pressure, and having a frequency approximately corresponding to the speed of the alternator, what would be the condition under which the alternator would fall into step with the supply current, and what would be the relation between the current passing and the mechanical energy given off? Also, how would this relation be affected by variations in the strength of the field? This problem was also treated by graphic methods, and it was found that the only and sufficient condition, for successful parallel working, was a sensible amount of self-induction in the armature circuit. It was well known that alternators having no iron in their armatures could not be run in parallel, except by the adoption of some such expedient as choking coils; also that parallel running was feasible with those alternators which had iron-cored armatures. If a machine were run at constant speed on open circuit, and with different strengths of exciting current, different terminal E.M.F.'s were obtained. A characteristic could then be plotted, the abscissas of which represented exciting power, whilst the ordinates represented terminal E.M.F., which in this case was the same as the induced E.M.F. Having obtained this curve, which the author suggested should be called the "static characteristic," the dynamic characteristic of the machine was determined for a certain current through the armature, by so adjusting the resistance in the external circuit, that for all exciting powers the current remained the same. The curve so obtained must obviously lie wholly under the first curve, and the difference between the ordinates of the two curves depended upon the choice of current for which the second test had been made, and upon armature-resistance and self-induction. Besides these two curves there was a third—namely, that obtained when the machine was driven as a motor running light. To find this curve it would be necessary to have at disposal at least two similar machines, using the one as generator and the other as motor, and during the test the field-strength of both machines would have to be regulated, so as to keep the current at its predetermined value. Thus, a "motor-characteristic" would be obtained, lying wholly above the "static characteristic." As the last experiment was, however, only possible if two machines could be tested at the same time, and was also somewhat delicate, another method of investigation was desirable. This could be done by using one of the author's diagrams to deduct the motor-characteristic from the two other curves, the experimental determination of which presented no difficulties whatever, and would, indeed, be made as a matter of course in the ordinary test of the machine before it was sent out from the manufacturers. Diagrams were shown which contained these various curves as determined for one of the author's machines, constructed for an output of 60 kilowatts.

In any dynamo machine there were two causes for heating, in addition to purely mechanical friction. These were the resistance of the conductors, and the change of magnetisation of the iron parts of the machine. As regarded the first cause, the liability to the generations of eddy currents in the armature conductor was much greater with alternators than with continuous-current dynamos, and in alternators it varied with the construction of the armature to a greater degree. When the armature contained no iron, the heating from eddy currents was much greater than when such a core was used, and the armature conductor must therefore be made in the form of a very narrow strip. The other cause of the generation of heat—the change of magnetisation in the iron parts—could be minimised by lamination, but never entirely avoided. In direct-current machines the heating from this cause was, however, generally so small that no account was taken of it, except when the induction in the armature core was pushed beyond 18,000 or 20,000. In alternators, a much lower induction produced sensible heating, and it was for this reason that the maximum induction must be fixed at a very low figure. With a perfectly laminated core, the heating was attributed to an effect which Prof. J. A. Ewing called "hysterēsis," and which might be described as molecular friction. This scientist had experimentally determined the energy required to carry certain samples of iron through a complete cycle of magnetisation of varying degree, and the results had been published in the "Philosophical Transactions." They were given in ergs per cubic centimetre; but as these units were rather inconvenient for application in the workshop or drawing-office, the author had in the following table, which referred to annealed wrought iron, translated them into watts per ton and h.p. per ton.

Induction.	Watts per ton $n = 100$.	H.P. wasted in heat.
2,000	650	0·87
3,000	1,100	1·48
4,000	1,650	2·21
5,000	2,250	3·02
6,000	2,900	3·89
7,000	3,750	5·03
8,000	4,450	5·97
9,000	5,550	7·43
10,000	6,650	8·90

Modern transformers were provided with a core of laminated iron, which was symmetrically placed in respect to the two windings, so that the same induction passed through both the primary and the secondary coils. Under these conditions the E.M.F. induced in the two circuits was simply proportional to the number of convolutions they respectively contained, and the terminal E.M.F.'s were found by adding in the case of the primary, and subtracting in the case of the secondary, the loss of pressure due to the resistance of the coils. In a properly designed transformer, this loss of pressure should not exceed about 1 per cent. of the terminal pressure, so that the maximum difference in the pressure maintained in the secondary circuit between the lamps, when the apparatus was used for parallel distribution, did not exceed 2 per cent. between full load and no load, provided the pressure in the primary circuit was kept constant. Such a small variation in the pressure was well within the limits attainable in direct lighting, when a compound-wound dynamo was driven from an engine with a fairly good governor, and the corresponding variation in the illuminating power of the lamps was sufficiently small to be tolerated. A greater variation, especially if it occurred suddenly, would, however, not be permissible; and the question, therefore, arose as to what rules should be followed in designing transformers so that they might as nearly as possible be self-regulating. The obvious answer was, make the resistance of the circuits as small as possible, and this might be accomplished in three ways: 1. By using wire of large area. This expedient naturally increased the weight, bulk, and cost of the transformer, and must, on account of commercial reasons, not be pushed too far. 2. By employing a core approximating to a circular or quadratic section, so as to decrease the perimeter of the coils. 3. By working with a high induction, or with a high frequency. The mean E.M.F. in volts, induced in the coil of a transformer, could be expressed by the following formula:

$$e = (q)\, 2\, \pi\, n\, z\, \tau\, 10^{-8},$$

in which (q) was a coefficient denoting the ratio between the maximum and the mean E.M.F., n was the frequency, z the total induction in absolute units, and τ the number of turns contained in the coil. The larger z, and the smaller n, might be the length of wire, and therefore its resistance. On purely theoretical grounds it would thus seem that a small core strongly magnetised, and as high a frequency as the alternator could be constructed to give, would produce the best results. In practice, however, this conclusion was wrong, and the heating of the iron core in consequence of hysterēsis must be taken into consideration. Since a transformer was an apparatus at rest, and was frequently placed in a position where the cooling effect of the air was small, the ratio between heat generated and available cooling surface must be very different from that permissible in a dynamo, and it was this ratio which was the true limit to the output of a transformer. The armature of a dynamo was not subjected to excessive heating if a cooling surface of about one square inch per watt was provided. In a transformer, the amount of cooling surface should be at least three times, and if possible, four or five times as great, especially as it was somewhat difficult to determine, in a body of such complicated shape, what was and what was not effective cooling surface. From the above table it was easy to calculate for any induction, frequency and weight of the active iron in a transformer, what the heat of the iron would be; and, adding to this the heat of the copper, the total cooling surface required to keep the apparatus at a safe temperature could at least approximately be determined, or the limit of output for any given transformer could be approximately found.

The question of frequency, alluded to in connection with alternators, was also of considerable practical importance with regard to the transformers, and it was much to be desired that electrical engineers should adopt a common standard. The following was a list giving the average frequencies adopted by several designers: Ferranti, 67; Lowrie-Parker, 88; Mordey, 100; Zipernowski, 42; Kennedy, 60; Kapp, 80; Westinghouse, 133. Taking the average of European practice, the frequency was 73, or 8,750 reversals per minute, whilst the American practice was 16,000 reversals per minute. This large difference might, to a certain extent, be accounted for by the general preference of European engineers for machines running at moderate speeds; but even when making due allowance for this circumstance, it could hardly be assumed that, had actual practice shown the value of a very high frequency, electrical engineers would not have found means to obtain it. As a matter of fact, most makers of alternators had started with a much higher frequency than they had finally adopted. It should also be remembered that the higher the frequency the greater was the loss of conductivity in the mains, owing to the unequal distribution of current throughout their cross-section.

The author then discussed the questions of alternate-current motors on the Ferraris principle, and next passed on to a description of the different modern alternate-current machines most in use. Constructive data were given for the Ferranti, Mordey, Kennedy, Kapp, Lowrie-Hall, Westinghouse, and Zipernowski machines; and in most cases the actual performance of the machine was compared with the calculated E.M.F., so as to show within what limits the author's formulas for alternators of different types were in accord with experimental results.

ELECTRIC LIGHT SCHEME FOR HARROW.

An important meeting was held at the Local Board Offices, Harrow, on Tuesday evening last, "to receive from Mr. R. E. Crompton (senior managing director of Crompton and Co.) a practical proposal on the introduction of the electric light into Harrow."

Mr. R. B. Hayward was in the chair, and there were also present: Dr. Stevens, Messrs. W. B. Walker, T. Dell, J. W. Paine, A. J. Batchelor, J. A. B. B. Bruce (members of the Lighting Committee), the Rev. F. H. Joyce, the Rev. W. D. Bushell, Messrs. A. G. Watson, G. Griffith, B P. Lascelles, J. E. Marshall, E W. Howson, W A. Hewllett, W. F. Taylor, F. Taylor, E. C. Trevor, J. L. Chapman, R. E. H. Fisher, D. Pitcairn, etc.

The **Chairman** said that before introducing Mr. Crompton he had better perhaps define the position of the Board in regard to the matter they had met to discuss. They would recollect that last autumn a public meeting was held, at which the question was discussed, and a resolution was passed requesting the Local Board to take up the matter and look into it. The Board referred it to the Lighting Committee, who inspected a very successful lighting station under the auspices of Mr. Crompton. A short time ago Mr. Crompton offered to come down and explain a scheme, and the offer being accepted this meeting was arranged.

Mr. Crompton, who was then asked to address the meeting, said he had come down there to try and extend the use of electric light. It was somewhat encouraging that this was not the only place at which he was hopeful of doing good work. He had to visit three or four other towns this week where they had seriously resolved to take the matter up. There was a great move in the direction of an increased use of electric light, more so on the Continent than in England. There was no need for him to detain them by speaking about the advantages of the electric light. All of them had seen enough of it to know that both from the point of view of health, and comfort, and convenience it was very desirable. The matter of the distribution of electricity was sufficiently perfected to enable him, as representing a firm of contracting engineers, to lay a scheme before them with confidence, for which his company would take part payment in shares, and this scheme would be as good an investment as gas and water shares had been in the immediate past. Great doubts had been cast upon electrical distribution as a remunerative investment. The cause was this. A few years ago a great many companies started which were merely speculative companies for the promotion of certain patent rights. Nearly all of them came to grief, and a large number of people consequently pulled their purse-strings tight afterwards. It was then a most uphill job to persuade anyone to invest in that form of undertaking. It took him three years to persuade people to supply the capital for the central station at Kensington, where their results had been so successful that they had found many imitators. Many large central stations were going to be started in London, and no doubt the aspect of the City next year would be widely different to what it was at present. In order to manufacture cheaply, it must be done in large quantities. Here at Harrow it was not fair to suppose that they could get an income of £2,500 or £3,000 in the first two or three years, but they would have a substantial nucleus to work upon in the shape of the school. Then, taking into account the high-class residential property, he believed a handsome profit would be yielded on the capital, if the capital was not too large. He had chosen the old waterworks as the site for the generating station, and his scheme was based on the use of that site. He had come to the conclusion that 3,000 lights could be supplied from a central station for a capital sum not exceeding £6,000, of which his company would be quite prepared to find £1,000. Mr. Crompton then explained the two well-known methods of distributing electricity—viz., the alternating transformer and the battery transformer, saying that he thought the former was best for Harrow. He proposed to use overhead wires over the piece of ground between the station, and the back of the school racquet court, from which point the mains would be underground. It was impossible that a large bid should be offered for the old water works, and he had fixed the rent at £100 a year. In the case of the underground mains, a concrete trench would have to be made, and a continuous culvert formed, of about a foot square. Underground mains had hitherto been an uncertain part of the investment in electrical plant, no one knowing how long they would last; but he took it for granted that if they eliminated all perishable material, and stuck to pure copper and porcelain, it could be maintained at 2½ or 3 per cent. on the original cost. Two or three years ago it was flung in their teeth that they knew nothing about the cost of electricity. It was untrue then, and far more untrue now. At the time he started the Kensington Company he guaranteed that the cost would not exceed £600 a year, and they had never exceeded £400 a year. He was pretty certain that the figures he was about to give them would be within the mark. If he made a mistake, it would fall on the company and not on the investors. He had supposed that £1,200 was to be obtained as revenue from the school and the houses connected with it, and it would be an extraordinary thing if another £1,200 could not be obtained from other private consumers. The cost of producing a supply sufficient for this demand would be £1,450 a year, which would include £600 for depreciation every year. The consumers would have to pay by meter. It had been said that they had no electric meter, but there were two or three which the consumers could choose from. He would give them the working costs in detail: Coal, £200; stores, £50; maintenance and clerical staff, £270; wages, £155; repairs, £150; depreciation, £600. If their scheme was only to supply what would bring in an income of £1,200, it would only reduce the costs by about £200. With an income of £1,200, therefore, and a scheme accordingly, they would just meet their expenses. Every private house above that would be pure profit. As to the investment being profitable, it depended upon whether they got custom outside the school—£800 of such custom would enable them to pay a dividend of 10 per cent. Any attempt to start a company on a smaller scale would not be economical. It might give the thing a start, but it certainly means a deferred profit. It would be a struggle for years; they would get their electric light, but probably no profit.

The **Rev. W. D. Bushell** questioned Mr. Crompton as to the cost it would mean to the consumers.

Mr. Crompton said that in Kensington the electric light costs 5s., as against gas at 3s. per thousand, but he had known cases where people whose gas bills had been £15 a year had paid £12 or £13 for electric light. This was simply because of the better facilities for turning off and on, and in the case of electricity many lights were saved, which it was not possible to do without in the case of gas.

Mr. Bushell then put a question as to the cost of fittings.

Mr. Crompton said the cost varied. In some cases it was as low as 27s. per light, whilst in the better class of house it was sometimes as much as 45s. a light.

Mr. Bushell: Will £6,000 be all the capital?

Mr. Crompton: £10,000, of which £6,000 would be called up.

Mr. Pitcairn: Is not the alternating system dangerous under any circumstances?

Mr. Crompton: No. Competition has given rise to the statement, but it is absolutely untrue.

Mr. Pitcairn: But it is the high pressure.

Mr. Crompton: It is not brought into houses.

Mr. Pitcairn: Well, accidents might happen in the streets, then?

Mr. Crompton: That means you must have the work substantial. The risks are infinitely less than in the case of gas; but if damage is done it falls on the company, not the consumers.

Mr. Griffiths: In case of a breakdown, will you have extra dynamos?

Mr. Crompton: Yes; one will be held in reserve.

Mr. Paine: Do I understand, as compared with gas, the consumers will pay 5s. a thousand?

Mr. Crompton: A little less—about 4s. 9d.

Mr. Paine: Our public lamps extend for miles, and we are charged at the rate of 4s. a thousand—will you be able to compete?

Mr. Crompton: We should take them at a loss sometimes.

Dr. Stevens: Mr. Crompton has not mentioned street lighting in his scheme.

Mr. Crompton: The Cheltenham Town Council have insisted on the lighting of the town, and the most frequented thoroughfares will be lighted with arc lamps, leaving the outlying streets to be lighted with oil lamps.

Mr. Pitcairn: Here we have a gas which is dear and not so pure as in London.

Mr. Crompton: Unless you have the arc lamps there is very little advantage in having a light outdoors.

Mr. Pitcairn: But you would be a rival to the gas company.

Mr. Crompton: It's a mistake to talk about shutting out gas works. There is a great future for gas for heating purposes, and some look upon the gas jet both as their light and fire. I don't think we shall tread upon each other's toes for the next seven or eight years.

Mr. Paine: Can you point to any place similar to Harrow where it is worked at a profit?

Mr. Crompton: Tamworth, in Australia. There they paid 6 per cent. after the first year.

Mr. Paine: It is not very encouraging over at Barnet. We want to profit by something which is in existence, and not to venture on an experiment.

Dr. Stevens: Is it merely a scheme for the school and the private consumers, or is it to include street lighting?

Mr. Crompton: In drawing up my scheme I have looked to the most certain source of income. I don't want to go in for the lighting of the streets if I can help it.

Mr. Bushell: What is the course to pursue in forming a company?

Mr. Crompton: The company or the Local Board will apply for a license.

Mr. Trevor: Within what sort of radius will your scheme work?

Mr. Crompton: It covers a length of 1,500 yards, but with overhead wires we can supply two or three miles.

Mr. Bushell: How far would the consumers be in the power of the company as to the price varying?

Mr. Crompton: I should say the price would not be raised, as that would mean failure.

Mr. Gunn: Supposing I had 20 lights in my shop and house, would they cost me £40?

Mr. Crompton: I should say about £30 in your case.

Mr. Gunn: That would be a large sum.

Mr. Crompton: We have no difficulty in getting gentlemen to pay it when they find the light answers their purpose.

Mr. Bushell: How many lights would you require in this room?

Mr. Crompton: Four, and they would give a better light than the present.

Mr. Bushell: Then there is the saving in furniture.

Mr. Crompton: Yes; you would find the money paid for white-washing and plumbers' work would soon pay the cost of introducing the electric light.

Mr. J. G. Chapman said the dark ceilings were caused by the coal fires, as he had proved in his own house. He went on to speak of the Electric Light Company at Eastbourne, which, he said, had been reconstructed twice, and which had made no profit at all. Then, for ventilating purposes, gas was found to be necessary. It was used in all rooms of the Hotel Metropole for that purpose. In rooms where the electric light was used the atmosphere was stuffy, and the carbonic acid gas was not carried off, the top of the room being colder than the bottom.

Mr. Crompton agreed that gas assisted ventilation. In the Birmingham Town Hall four gas jets made the most perfect ventilation, but one electric motor would have done the work better. But in large rooms in London, in the season, where there were crushes, the electric

Digitized by Google

light caused a comfortable temperature, and there were no draughts to give the people colds. In the bedroom, too, the advantages of the electric light were enormous.

Mr. Holltum asked whether the light was likely to go out. If he had three or four ladies in his shop, and the light went out, it would be rather awkward.

Mr. Crompton said it could be rendered perfectly safe and reliable.

Mr. W. F. Taylor said he should like to make a few remarks about Mr. Crompton's figures. Last year, in a paper read before a meeting of specialists, Mr. Crompton said that the cost of the plant, etc., to supply 10,000 lamps would be £57 000. That evening Mr. Crompton had told them that for 3,000 the capital required would be £6,000, and he would like to know how the two statements could be reconciled. According to his former statement 3,000 would cost £17,928.

Mr. Crompton explained that his former statement had reference to the mains in London, which were far more expensive to make. If Mr. Taylor examined his paper, he would find that the cost for the earthwork was enormous. Opening up streets in London was very different to what it would be here.

Mr. Taylor, having pointed out other differences in connection with the laying of the mains, asked how Mr. Crompton managed to get over the high peak in the load diagram which he was so much afraid of in connection with the alternating system last year, and afterwards remarked that he thought this meeting was on behalf of the ratepayers, and not on behalf of the schools.

The **Chairman** said it was not on behalf of the school.

Mr. Taylor said Mr. Crompton's scheme had only reference to the school.

The **Chairman** said it was not so.

Mr. Taylor said that many important parts of the district would not be reached by the scheme. He should like to know why Mr. Crompton had been invited.

The **Chairman** said he had offered his services, and the Lighting Committee thought it well to accept them. He was sure the Board would have heard any other firms if they had come forward.

Mr. Taylor said they did send a letter to the Local Board asking to be heard before the first meeting was held.

Mr. Paine said, as one of the committee, it looked a little like rushing the matter to have a single firm down without giving any other firms an opportunity to be heard—(**Mr. Taylor:** Hear, hear)—and then to immediately form a committee.

The **Chairman** said he thought it most desirable that a committee should be formed apart from the Board. The Lighting Committee could continue their enquiries if it was wished.

Dr. Stevens said he had had nothing to do with this meeting, although his name had been added to the Lighting Committee.

The **Chairman** said he must apologise for the mistake; he took it to be the ordinary Lighting Committee.

Mr. Dell said they were very much indebted to Mr. Crompton for coming there and putting the matter before them in such a fair and gentlemanly manner. He agreed with the Chairman that it would be better for a committee to be formed apart from the Board to continue the enquiries. They did not wish to ignore Mr. Taylor's company, and would be quite willing to hear them on the subject. He proposed a vote of thanks to Mr. Crompton.

Mr. Marshall said that it was the duty of the Lighting Committee to report to the Local Board, and he hoped they would do so. He agreed that it would be best to have an outside committee to consider the question of domestic lighting, but thought this was hardly the occasion on which it should be formed. Referring to Mr. Taylor's remarks about the school, he pointed out that Mr. Crompton only spoke of it as a nucleus, and added that if the school did have the electric light, it would be serving the town, inasmuch as it would be possible for people then to have this luxury.

Mr. Paine then seconded the vote of thanks to Mr. Crompton, which was carried unanimously, and the meeting terminated.

LEGAL INTELLIGENCE.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY v. HOLLAND.

The following judgment in this case was delivered on Monday last. It has, according to our views, been unnecessary to repeat at full length the evidence given in this appeal, as most people outside those immediately engaged in the struggle concern themselves only with the verdict, which is herewith given in full.

The Attorney-General (Sir R. Webster, Q.C.), Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Bremner appeared for the plaintiffs; Sir Horace Davey, Q.C., Mr. Finlay, Q.C., and Mr. J. C. Graham for the defendants (the respondents).

Lord Justice Cotton: This was an action brought against the defendants in respect of two patents, both of which have become vested in the plaintiffs, and they sought to restrain the infringement of those patents. One of them was a patent granted to Cheesbrough. In respect of that Mr. Justice Kay decided in favour of the plaintiffs, and granted an injunction and consequential relief. As regards the other patent, which was one obtained by Edison, and the date is the 10th November, 1879, he decided against the plaintiffs, and hence the appeal. Now this patent has been before this Court, and I had the advantage or disadvantage of being one of the members of the Court on the previous occasion. There was a difference of opinion between myself and the other Lords Justices as to the true construction of the specification, but I consider myself bound by the decision of the Court on that point, and in my opinion, except on questions of fact, which, of course, must be decided by the evidence in this action, the Court ought to consider itself bound by the previous judgment. In the previous case the Court held that if there was no anticipation of the invention claimed by Edison it was a good subject matter for a patent, being for a combination many parts of which were not new, but which was rendered useful by a carbon bridge or burner, described as a filament, which the majority of the court held not to be confined to the particular things described as filaments in the specification, but I think held that it must possess the characteristics pointed out in the specification, must be substantially the same as regards these characteristics, as the particular filaments described in the specification. The Court then decided that the utility of the invention was established. Here then was a great effort made to contest the utility of the invention. This was principally based on the contention that no successful incandescent lamps were made in accordance with the specification of November 10, 1879, and without further improvements. Inventions for the improvement of the carbon filaments followed quickly on the patent of November, 1879, which greatly assisted in the manufacture and durability of the burner of the incandescent lamp of November, 1879. That, in my opinion, was a useful combination, and a patent is not to be defeated simply because subsequent inventions improved the patented article, or because in consequence of subsequent improvements no article was, in fact, made in accordance with the specification. But in my opinion it is established by the evidence that, in fact, incandescent lamps were made by Edison in accordance with the specification of November 10, 1879, and even sent by him to Dr. Hopkinson, and publicly run by him in March, 1880. I do not see any fact now brought before us which ought to induce the Court to depart, or would justify the Court in departing, from the previous decision of the Court on the question of the invention being useful, and being the good subject matter for a patent. But we then come to the objection of want of novelty, which is a question of fact. The only alleged anticipation which I need consider is that of Swan's lamp, "F. J. B. 1," exhibited in December, 1878, and February and March, 1879, by Mr. Swan. In the previous case, on the evidence then before us, I thought this lamp would, on the construction put by the majority of the Court on the specification, be an anticipation. How does the evidence now stand? It is now admitted that the carbon burner of Swan's lamp was formed into its shape before it was carbonised; and this removes one of the points much relied on by the plaintiffs in the former action. But we have now evidence, which was not before the Court in the former action, of what was being done by Mr. Swan and by Mr. Stearn after the experimental trial of this lamp. We have the evidence of Mr. Swan and of Mr. Stearn. We have had before us the lamp "F. J. B. 1," and we have the letters written by Stearn to Swan in 1879 and 1880, which were apparently admitted by counsel to show what was being done by Swan and Stearn. We see that "F. J. B. 1" was treated by them as a failure, and that their attempt to correct its defects led to lamps which differed more widely than did "F. J. B. 1" from the lamp described in Edison's patent. This evidence assists the conclusion at which the Court arrived in the former action that Swan's lamp of 1879 was not a success, and, I think, enables me to come to the conclusion that this lamp was an experiment which failed, and was abandoned, and that the difference introduced by Edison was one which changed failure into success. But it was contended by the respondents that, in fact, Swan had used for electric lighting incandescent lamps with carbonised thread burners before the 10th November, 1879. Two witnesses, Proctor and Heaviside, stated that carbonised thread lamps were, in 1879, used by Swan. There is no ground for imputing dishonesty to these witnesses, but there was direct evidence by Swan that he did not make any thread-carbon lamp before 1880, or before a fire, the date of which is fixed as 17th January, 1880, and I am satisfied that the witnesses were mistaken in fixing the date as 1879. Reliance was placed by the respondents on a lamp made by Bernstein, not as an anticipation of Edison's patent, for it was not made till after 1879, but as showing that Swan's lamp was a practically useful one. But though Bernstein's lamp has a bridge or conductor, a pencil of carbon like "F. J. B. 1," it has a different junction with the leading wires, which probably obviates some of the difficulties which prevented Swan's lamp becoming a success. Then I come to an objection which was much relied on by the defendants, which was not raised in the former action, and which is now supported by a great deal of evidence. The objection, taken as a whole, was that the specification did not sufficiently show how the invention is to be carried into effect. It is necessary that this should be done, so as to be intelligible and to enable the thing to be made without further invention; not as was pressed on us by an ordinary workman, but by a person described by Lord Ellenborough in Huddart *v.* Grimshaw (Webster's Patent Cases, pages 85-87), as a person skilled in the particular kind of work, or as said by Lord Loughborough, in Cartwright *v.* Nightingale (Webster, page 6), a person conversant in the subject. But in my opinion it is not necessary that such a person should be able to do the work without any trial or experiment, which, when it is new or especially delicate, may frequently be necessary, however clear the description may be.

One of the principal subjects of attack was that part of the specification which gave directions for making a combination of lampblack and tar to form a material to make the filament to be carbonised. Before the experiments which, by the direction of Mr. Justice Kay, were made under the supervision of Prof. Stokes, the defendants' witnesses said that useful filaments could not be made out of the material, and Prof. Crookes was particularly strong in his ridicule of the idea that tar putty could be practically useful. Gimingham, a young man in the employ of the plaintiffs, produced and proved lamps with burners made of tar putty filaments, and after the experiments made before Prof. Stokes the defendants contended before us, without any support from the evidence, that the material could not be effectually prepared without a trade secret which they said had only recently, during the course of the trial of the action, come to the knowledge of the plaintiffs, and probably had been communicated from

Digitized by Google

America. It was said that the secret was the necessity of kneading the material for a length of time, and with the exercise of great pressure. In fact, Gimingham had for the trial of the previous action made lamps with tar putty filaments which were made exhibits in this action, and though there are no express directions in the specification how this tar putty is to be prepared, it is stated that the material can be rolled into threads as small as 7-1,000ths of an inch, and I think it would be obvious to any intelligent workman who wished to prepare the material that it must be kneaded so as to make it perfectly homogeneous, and to prevent any breaking of the thread in consequence of any particle of lampblack not being perfectly amalgamated with the tar. I think that this objection fails. But it was contended that lamps with tar putty filaments had not sufficient endurance to make them practically useful. No point was made of this before Prof. Stokes, so that no experiments were made to test this question. In fact, on the evidence before us, many of these lamps were shown to have run for a sufficient time to prove that they could not be considered failures in this respect. Another objection taken to the specification was that no sufficient directions were given as to the carbonisation of the filament. The specification says (page 3) "a cotton thread properly carbonised," and speaking of the thread of tar putty, that the "tar may be carbonised in a closed chamber by subjecting it to a high heat," but no directions are given as to how this is to be done.

Before the experiments made under the supervision of Prof. Stokes, it was said that carbonising the filament in a closed chamber without any packing, or with a packing of sand, which was suggested by Sir F. Bramwell, was impossible, as the filament would be reduced to ash. But this was proved to be unfounded, and before us it was still contended that no sufficient directions as to the mode of carbonisation were given. Carbonisation was a well-known term. The ordinary process may be described as roasting without the presence of oxygen. This was well known and practised before the date of the patent, and Sir Frederick Bramwell in his evidence said that any person who knew the ordinary process of carbonising would succeed in carbonising filaments. But it was strongly contended by the defendants, and by some of their witnesses, that such slender things as filaments could not be carbonised in a closed chamber without being protected by packing, which the specification did not direct to be adopted. In fact, filaments were, as sworn by the witnesses of the plaintiffs and demonstrated by the experiments made before Prof. Stokes, successfully carbonised in closed crucibles or boxes without any packing; moreover, though the specification says nothing about packing, any skilled workman conversant with carbonisation would take the ordinary process of packing to exclude oxygen, and would, I think, know that when so delicate an article as a filament is to be carbonised, the greatest care would be necessary to prevent any possible access of oxygen. It is true that there was no trade in carbonising anything so delicate as these filaments, but great care only in exercising a known process and applying it to an unusually delicate article, and no invention would be necessary. When the defendants' witnesses failed in carbonising the filaments, I think that they did not use reasonable care to exclude oxygen, as shown in the case of using porous crucibles. I am of opinion that this objection also fails.

Another point urged by the defendant was that the coating with a non-carbonisable substance was injurious. The result of the evidence is that when the coating is a thin one the process can be and is done without any injurious results. But then it was objected that the specification did not direct the thin coating; and it was objected, and so held by Mr. Justice Kay, that this thin coating was a mere pretence of coating, and it was dusting only. But it appears from the evidence of Mr. Crookes that he had himself, in fact, adopted the same method as was adopted on behalf of the plaintiffs for this coating. The process was, I think, in the specification, proposed as preventing the filament of tar putty from sticking together during the process of carbonisation, and what I have said about Mr. Crookes, I think, shows that the process which produced the so-called dusting must be considered as that which would naturally be adopted. I think that this objection also fails.

I have dealt with the principal points urged by the defendants, though shortly, in order to avoid the extreme length which would be necessary if I were to deal minutely with the various points. In my opinion the plaintiffs are entitled to judgment, and the appeal must be allowed.

Lord Justice Lindley: The validity of the patent in question on this appeal is disputed on two broad grounds—viz. (1) because the patentee has not particularly described and ascertained the nature of his particular invention; (2) because he has not particularly described and ascertained in what manner the same is to be performed. The 9th Section of the Patent Act, 1852 (15 and 16 Victoria, chapter 83), under which the plaintiffs' patent was granted, imposes upon the patentee the necessity of complying with both of these conditions in order to sustain his patent, and the patent is bad if he fails to perform either of them. The two conditions, although often confused and overlapping, are really distinct, and it is always necessary to keep each clearly before one's mind, and not to commit the mistake of supposing that compliance with one is necessarily compliance with the other.

The first condition imposes upon the patentee the necessity of stating in clear and intelligible language what his invention really is, so that others may know what addition the patentee has made to what was known before, so that they may know what they are not at liberty to do without his consent during the existence of the patent; in other words, so that they may know what the monopoly is that is granted to the patentee. The nature of the invention must be stated both in the provisional and in the complete specification; but, whilst it is sufficient in the provisional specification to state the nature of the invention in general terms, it is necessary in the complete specification to "particularly describe and ascertain it."

The second condition imposes upon the patentee the necessity of stating in clear and intelligible language in which manner the patented invention is to be performed, so that others may learn from the specification how practically to avail themselves of the patented invention when the patent has expired; how they are to do what is necessary to carry out the new invention, the nature of which has been previously described. This condition applies to the complete specification only; there is no necessity to state in the provisional specification how the invention is to be performed.

With reference to the degree of clearness and distinctness of the language necessary to be used in order to comply with those conditions, it is obvious that no hard and fast rule can be laid down, the degree of clearness can only be stated in language which itself admits of considerable latitude in its application. On the one hand, the patentee must make the nature of his invention and how to perform it clear and intelligible; on the other hand, it is not necessary for him to instruct persons wholly ignorant of the subject matter to which his invention relates in all that they must know before they can understand what he is talking about. The patentee is adding something to what was known before, and he does all that is necessary, as regards the language he uses, if he makes the nature of his invention and how to perform it clear and intelligible to persons having a reasonably competent knowledge of what was known before on the subject to which his patent relates, and having reasonably competent skill in the practical mode of doing what was then known. In complying with the first condition—*i.e.*, in describing the nature of his invention—the patentee does all that is necessary if he makes the nature of his invention plain to persons having a reasonably competent knowledge of the subject, although from want of skill they could not themselves practically carry out the invention. In complying with the second condition—*i.e.*, in describing in what manner the invention is to be performed—the patentee does all that is necessary if he makes it plain to persons having reasonable skill in doing such things as have to be done in order to work the patent, what they are to do in order to perform his invention. If, as may happen, they are to do something the like of which has never been done before, he must tell them how to do it if a reasonably competent workman would not himself see how to do it on the reading of a specification or on having it read to him. The principle to be applied to the language used to comply with the two conditions is the same for both; but one class of persons may understand only one part of the specification and another class only the other, and yet the patent may be valid. In a well-drawn specification the two conditions that have to be complied with are kept distinct; but in many specifications this course is not pursued. The nature of the invention and the manner of performing it are often described together. It may be that one set of words sufficiently discloses both the nature of the invention and the mode of performing it, as in Boulton *v.* Bull. But it may be, and sometimes is, very difficult to sever the two, and to see whether both are sufficiently described. Still, if they are, in fact, sufficiently described, the conditions must be held to be complied with, however difficult and troublesome it may be to arrive at the conclusion.

I have been induced to dwell at some length on the above matters, because of their importance in the present case, and of the danger of losing sight of the principles by which the Court ought to be guided in deciding it.

I proceed now to enquire whether these two conditions have been performed, and I will take them in the order in which they logically present themselves. First, as to the nature of the invention. This Court has had to consider this patent before; and, although there was a difference of opinion amongst the members of the Court, the decision of the Court was, as I understand it: (1) That the expression "carbon filament," on which so much turns, was sufficiently clear and definite; (2) that the nature of the invention was sufficiently described and ascertained, and was summed up in the second claim; (3) that the second claim was in substance a claim to "every combination of any carbon filament with any receiver made entirely of glass, through which any leading wires pass, and from which the air is exhausted"; (4) that the plaintiffs' "carbon filament" was essentially different from the carbon pencil used by Swan in his lamp, "F.J.B. 1," and that Swan had not by that lamp anticipated the plaintiffs' patent. The patent was upheld, notwithstanding the very wide nature of the second clause as construed.

This decision is, in my opinion, binding on us so far as the construction of the specification is concerned, but no further. I do not regard the decision as binding us upon the questions whether the conditions to which I have alluded have been performed or not; for these questions depend not only on the construction of the specification, but on evidence as to the previous state of knowledge, and as to whether a person of reasonable skill could, at the date of the patent, carry out the invention without further instruction than the specification gave him. I have, therefore, whilst taking the construction of the specification as settled, considered myself at liberty to exercise my own judgment on the effect of the evidence in this litigation.

The construction of the specification which I consider binding involves three points—viz.: (1) that the specification is not too vague and unintelligible to be construed by the Court; (2) that what is meant by "carbon filament" is reasonably plain from the specification itself; and, thirdly, that the second claim as construed by the Court is not so wide as to invalidate the patent. The meaning of the expression "carbon filament" appears to me to be the crucial point for determination when dealing with the question whether the nature of the invention is particularly described. This point, moreover, is, in my judgment, by far the most difficult in the whole case. Everything, I think, turns upon it; but as I was not a party to the decision, and the case will probably be appealed, I think it desirable to state that after much consideration and doubt I have come to the conclusion that what is meant by the expression "carbon filament" can be gathered from the instances given in the specification

Digitized by Google

and that what is meant is any thread which can be and is bent into the required form, and can be and is carbonised when so bent. The thread, as shown by the examples, may be a fibre or a group of twisted fibres, or, as is to be gathered from the tar lampblack instance, it may be an artificial substance pressed or rolled into thread or wire-like forms. The evidence shows that at the date of the patent the expression "carbon filament" was new as applied to electric lighting. Its meaning, or, in other words, the sense in which it is used by the patentee, must therefore be gathered from the specification. The sense in which the patentee has used the expression "carbon filament" can, in my opinion, be gathered from the typical examples given in the specification and referred to in the judgment of Lord Justice Fry in the former case. At the top of page 253 the Lord Justice says: "It is not needful for us to pursue the description of all the processes given by the specification, but we will refer to the forms of carbon conductor described. The first form referred to as suitable is a 'cotton thread properly carbonised,' which is stated to offer from 100 to 500 ohms resistance to the passage of a current; the second form of conductor referred to is any fibrous vegetable substance which will leave a carbon residue after heating in a closed chamber. To this class may be referred the cotton and linen thread wood splints, and paper coiled in various ways to which Mr. Edison refers. The fourth form is such fibrous material as before mentioned, rubbed with a plastic compound of blacklead and tar. The fifth form is a carbon filament made of a combination of tar and lampblack, or plumbago or carbon in other forms, the lampblack and tar being subsequently carbonised by being subjected to high heat in a closed chamber. Mr. Edison observes that small pieces of such a compound may be rolled out in the form of a wire as small as seven one-thousandths of an inch in diameter. The sixth and last form described is a carbon filament of the kind lastly described, but coated for the purpose of support with a non-conducting, non-carbonising substance." The size of the filament is not stated; but it is quite clear from the objects to be attained that it must be long and thin, and nothing more definite is necessary to be stated.

Having arrived at that conclusion, it follows that in my opinion the patentee has "particularly described and ascertained the nature of the invention."

The next thing is to consider whether he has sufficiently described "in what manner the same is to be performed." This is a pure question of fact, and is in no way touched by the previous decision of the Court. Mr. Justice Kay, however, has found this against the patentee. Having carefully attended to the evidence and to his judgment, I have come to the conclusion that I am unable to agree with him; and I cannot help doubting whether he would have arrived at the same conclusion if he had had the advantage which we had of hearing the Attorney-General's reply to his opponents.

The defendants, in the first place, endeavoured to make out that carbon filaments could not be made as described by the patentee. The evidence on this point was so conflicting that Mr. Justice Kay called in an expert to assist him. This gentleman's report is absolutely conclusively in favour of the patentee, upon the question whether carbon filaments can or cannot be made as described. Beaten on this point, the defendants contend that no competent workman could have made carbon filaments according to the specification without further instructions than are there given. If it be meant that few competent workmen could make them without some practice, I think the contention is well founded; but this is not sufficient to invalidate the patent. If a person is told to carbonise a thread, and for want of thought or practice he takes a porous crucible for the purpose, and does not protect his thread and fails, when, if he had packed this crucible, or had taken a non-porous crucible, he would have succeeded, his failure can hardly be said to be the fault of his instructor, if a little thought and consideration would have shown that a packed crucible or a non-porous crucible was the right one to employ. The fact that a workman may use a wrong tool when he has a right one, which a little thought will lead him to see ought to be used, does not warrant the inference that a specification is bad if it does not tell him which tool to use.

Again, with respect to tar putty: the object to be attained is plain; the putty must be kneaded so that it can be rolled out thin without a break or flaw. Practice alone can teach any man how long and how hard he must knead. If he stops too soon and fails, is it the fault of the patentee? I should say certainly not. A similar observation applies to coating with a non-conducting, non-carbonisable substance. If the coating is made lightly by dusting all goes well; if too much is put on failure is the result: a little practice is all that is required. Mr. Crookes himself tried dusting as the most natural way of coating; and the unsuccessful coating experiments were not repeated before Prof. Stokes. I feel the great difficulty of describing in words the distinction between an amount of practice without which failure is probable, but the necessity for which does not destroy a patent, and an amount of experiment and invention, without which failure is certain, and the necessity for which destroys a patent. The test, however, by which to decide such a question is, I think, to be found by asking whether anything new has to be found out by a person of reasonably competent skill in order to succeed if he follows the directions contained in the specification? If yes, the patent is bad; if no, it is good so far as this point is concerned. Practice is one thing; experiment and trial are something different. On this point I derived considerable assistance from the judgment of the late Master of the Rolls in Plimpton *v.* Malcolmson, and from the judgments in Simpson *v.* Halliday and Macnamara *v.* Cooke. It is settled that a patentee who does not disclose the best method known to him of carrying out his invention does not comply with the second of the conditions to which I have before referred. But if a patentee says that something must be done which a reasonably competent man would know how to do, the patentee need not tell him how to do it, nor warn him to be careful, and to exercise such forethought and attention as the delicacy of the process to be used, or the material to be employed plainly demand.

The evidence upon the question whether at the date of the patent a reasonably competent man could make carbon filaments without further instruction than is given in the specification, or without further experiments, was undoubtedly conflicting, and Mr. Justice Kay, who saw the witnesses, came to the conclusion that further instruction and experiment were necessary. The Attorney-General, however, convinced me that on this point Mr. Justice Kay was mistaken. I cannot myself come to the conclusion that the patentee has kept back any secret that he possessed by virtue of which he could in 1879 make carbon filaments better than other persons possessed of reasonable skill, and who followed the directions contained in the specification with a *bona fide* desire to succeed. To ensure success, all that is necessary is carefully to follow the instructions there given, bearing in mind the objects to be attained, and that the filaments are extremely delicate and easily destroyed. That is, in my opinion, the fair result of the evidence; and the fact that Edison in later patents gave particular instructions as to the mode of carbonising, etc., only shows that he had then ascertained that those instructions were necessary to enable a competent man to attain the desired results. It cannot, I think, be inferred that in 1879 special instructions were necessary to enable reasonably skilful men to do what the specification of that date said must be done. The evidence on this matter is no doubt conflicting, but I cannot agree in thinking that the manner in which the invention is to be performed is not stated with sufficient clearness to support the patent. If this were really true it would have been found out long ago, at least so far as carbonising is concerned.

There remain, however, two other matters for consideration—namely, novelty and utility. The novelty depends on whether Swan's lamp, "F. J. B. 1," was an anticipation, for I am convinced that Proctor and Heaviside are wrong in the date they assign to the hairpin lamps made by Swan. The correspondence referred to by the Attorney-General is conclusive as to this matter. The lamp "F. J. B. 1" was held by this Court, in the action against Woodhouse, not to be an anticipation of the plaintiffs' patent, but it was then supposed that the carbon pencil used in it was carbonised after and not before it had assumed its final shape. This was a mistake, and was admitted to be so in this action.

The question of anticipation must be considered anew on the evidence before us. If Swan's lamp "F. J. B. 1" had been a success instead of a failure, it would, in my opinion, have been an anticipation of the plaintiffs' patent. The evidence, however, shows that it was a failure, and that Swan had not got the key to success. His own efforts to improve this lamp show that he was not thinking of filamentous incandescent carbons, but of other matters. Still, his lamp did give light for a time, and was very near, though, in my opinion, not quite, an anticipation. It was, in truth, an unsuccessful experiment. I agree with Lord Justice Fry in thinking that the point at which Mr. Edison's instrument departed from Mr. Swan's was crucial, and the departure, though slight, had all the merits of a new invention, and produced a new apparatus. Regarding the lamp "F.J.B. 1" as an unsuccessful experiment, this part of the case is governed by the principle of Murray *v.* Clayton, 7, Chancery Division, page 570.

The question of novelty, which I am now considering, is closely connected with, although really different from, the question as to the sufficiency of the description of the nature of the patented invention. Given Swan's lamp "F. J. B. 1" can it be said that Mr. Swan added anything to what was known at the date of his patent, and that he sufficiently described the nature of what he added? In my opinion he did; not, indeed, in words, distinguishing his lamp from Swan's, but by giving and describing a new type of body to be rendered incandescent, or, if I may use such an expression, a new type of thread. One mode of trying this question is to ask whether anyone would make such a thing as Swan's lamp, "F. J. B. 1," if he took Edison's specification as his guide. I am convinced he would not. He would avoid and not reproduce Swan's carbon pencil, and would adopt Edison's type of carbon in the carbon filament. The two may be made to shade off into each other until it becomes impossible to draw the line sharply between them; but this does not prevent a man from perceiving the difference between the two types, or from adopting the one which succeeds in preference to the one which fails.

There remains the question of utility. Edison's patent is said to be of no use; and the proof of this statement is said to be furnished by the fact that lamps are not made according to the patent even by Edison himself. The utility of the patent must be judged by reference to the state of things at the date of the patent; if the invention was then useful, the fact that subsequent improvements have replaced the patented invention, and rendered it absolute and commercially of no value, does not invalidate the patent. Such has been the fate of lamps made in the way described in Edison's specification. Such lamps appear to have been made and sent to England, but they were so soon improved that they at once ceased to be used in their original form. But lamps having the carbon filaments in combination with the other essentials mentioned in the second claim are in constant use, and their utility is proved by the fact that this particular combination is used by the defendants, and by everyone, in fact, who makes incandescent electric lamps. The utility of the patented invention, meaning thereby the above-mentioned combination, is incontestable; and Mr. Justice Kay's opinion to the contrary is, I think, to be attributed to the view he took of the construction of the patent, a matter which, as I have said before, I consider settled by the previous decision of this Court.

Before concluding, I ought to notice the very formidable objection taken by Mr. Justice Kay to the validity of the patent, on the ground that the second claim is for a monopoly of incandescent lamps containing a filament of carbon for a burner, and that such claim is far too wide, considering how much Edison had invented. Whether the view here taken of the patent is correct or not turns, in my opinion on what Mr. Edison did when he introduced "carbon filaments." That was, I think, a new departure of the highest importance in elec-

Digitized by Google

tric lighting, and if this be so the claim is not too wide. See Househill Company v. Neilson (Webster, page 683).

For the reasons above stated, I am of opinion that this patent, construed as it has been by this Court, is valid, and that the appeal ought to be allowed.

Lord Justice Bowen: In order not to add more than is necessary to the voluminous literature on the subject of this patent, I will express my views as briefly as possible. As regards the construction of the second claim, I think we ought to follow, on principle, what has been already decided by the majority of the Court in the case of the former action; but as I retain the same opinion as I then formed, this point becomes less material. The patent appears to me to claim in distinct and unmistakable language every combination of any carbonised filament with any receiver of glass, through which leading wires pass, and from which the air is exhausted. Whether a claim so framed is too vague or too wide, or unfit to be the subject of a patent, or whether it is wanting in novelty or utility, constitutes an enquiry which, in parts at all events, may be said to be bound up with questions of fact, and, as far as all such points are concerned, I think it desirable to judge this appeal *de novo* upon its independent merits.

Construing claim two as embracing all combinations such as I have mentioned, is it too vague? I see no reason to doubt that in the year 1879 the term filament, though new at that date as regards electric lighting, would, nevertheless, convey to the minds of ordinary persons of the class to whom this specification was addressed the idea of a slender thread or thread-like substance, and it seems to me that the specification indicates that the thread or filament was first to be formed and then to be subsequently carbonised. On page 2 of the patent, the thread is distinguished from a rod. "Heretofore, light by incandescence," says Mr. Edison, "has been obtained from rods of carbon. I have discovered that even a cotton thread, if properly carbonised," will produce the requisite effect. The instances given in the specification, which are enumerated in the judgment of Lord Justice Fry and myself in the previous appeal, and in the judgment of Mr. Justice Kay in the present action, are illustrations of the sense in which the term, which appears to me to be in itself intelligible, is used. The term filament is nowhere defined. It is a descriptive term, not a definition. But it appears to me to indicate the nature of this particular factor in the combination in a way that describes and ascertains the nature of the invention so as to render it plainly intelligible to a skilled person of the class to whom the specification is addressed—languages which embodies old law, but which is tersely expressed in Lord Herschel's judgment in the Badische Anilin case (2. Appeal Cases). The merits of the filament, as distinguished from a rod, are manifest. The filament, or thread, has an extremely small sectional area; it is flexible before carbonisation, and resilient afterwards. It is true that these merits are not explained, but I know of no law which renders it incumbent on the patentee in such a case to explain them. It appears to me, moreover, to be proved, not only that every successful lamp since 1879 which is available for multiple arc lighting has employed a filament, but also that there is no proof yet that any filament cannot be adapted to the patented combination. If this is so, why is the claim too wide? It is not the fault, but the virtue of the invention that it covers so large a field.

We have been pressed with the argument that the Edison patent is useless, and that no lamp in the market has been made exclusively on the patent of 1879 without the aid of subsequent improvements. Improvements of real value followed with great rapidity on the patent, and were naturally utilised. Their rapid succession does not destroy the legal validity as regards usefulness of the original combination to which such improvements were felicitously applied. The utility of this invention, which was admitted in the Woodhouse case, has been challenged in the present action, but I think unsuccessfully, and the evidence shows that lamps made solely on the patent will and do succeed, although subsequent improvements have been generally engrafted on the original design.

Was "F. J. B. 1" an anticipation? We know now what the Court did not know in the last action, that the carbon conductor in "F. J. B. 1" was formed before it was carbonised. Was it a filament? The question is one of degree. I doubt whether it is one, and I still more doubt whether anyone who saw it would understand it to be such. But in any case I think "F. J. B. 1" never was more than an experiment which was unintelligible on account of its failure and barren of all fruit, and which was regarded even by its inventor as practically valueless in the race. The correspondence between Messrs. Swan and Stearn shows, I think, to demonstration that till the middle of the year 1880 Mr. Swan did not consider himself to be upon the right track. The dates put forward by the witnesses Proctor and Heaviside seem to be unreliable and inaccurate, and I think there is reason for believing that it was Mr. Edison's patent which led back the world of electricians to the true path. Certainly from the date of its exhibition the lamp "F. J. B. 1" disappeared from history, until it was exhumed for the purposes of the trial in the Woodhouse case.

With respect to the remaining points raised in argument before us, I have nothing to add to what has been said by my brothers. I think this patent constituted a new departure in electricity; that the specification sufficiently describes and ascertains the nature of the invention; and that no reasonably competent operative alive to the delicacy and care obviously requisite in forming and carbonising so slight a thing as a filament ought without any exercise of invention, but with reasonable watchfulness only and fair goodwill, to have been embarrassed in making and carbonising Mr. Edison's filaments. The appeal in my judgment should be allowed with the ordinary results as to costs; and I think I ought, in conclusion, to express my own personal obligation for the conspicuous clearness and ability with which this case has been placed before us at the bar.

A long argument took place as to the exact position the Anglo-American Brush Company was to take in this case, the plaintiffs claiming to treat as defendants the corporation, which was a third party in the suit. The final result of the argument will be seen in the discussion by the judges, as follows:

Lord Justice Cotton: A point has been raised here which is a curious one, but it arose simply after judgment, and I thought the matter was simply giving the judgment now to apply to both patents, which Mr. Justice Kay had given as regards the one which he decided in favour of the plaintiffs. But the plaintiffs now claim to treat the third parties as if they were defendants, not only in the way of making them pay costs, but also in the way of granting relief against them—granting an injunction, and consequential relief. As regards that, I think it would be wrong, because the third parties are not defendants. If a plaintiff has a direct claim against a third party, as soon as that is known the proper course is to amend the statement of claim and make him a defendant, and then the Court has all that jurisdiction as against the defendant, which it gains by serving that party with a writ, and bringing him in as a party to the action. Why that was not done here I cannot understand, except that possibly the plaintiffs did not like to bring in another person against whom they would be liable to costs, as they did before Mr. Justice Kay as regards this portion of the Edison patent.

One does not wish that there should be unnecessary litigation. I do not see that for that reason one could assume a power which, in my opinion, we have not got. It is very true that when this third party came in and desired to defend the action, and the direction was given, he might have had that liberty given on his undertaking to submit to any judgment which the Court might think fit to give as against him, supporting the interest of the defendant, and really being the person who ought to have been made defendant. But that was not done. The order which was made was simply an order in these terms, that he should be at liberty to appear at the trial of the action, and take such part therein as the judge shall direct, and the said Anglo-American Brush Electric Light Corporation, Limited, shall be bound by the decision of the Court in this action in any question as to the above indemnity which may arise between that company and the defendants. If the plaintiffs were not satisfied with that, they ought to have said, "No, that will not do for us, other terms ought to be imposed upon this third party;" but the proper course, looking now still to the origin of the jurisdiction, and that which brings a person within the jurisdiction of the Court, ought to have been for the plaintiff to amend his appeal, and say: "Here are the real persons who are disputing or infringing this patent, and who are making these things, which I say are infringements of the patents." That course was not taken for some reason; I do not know why. In my opinion, we have no jurisdiction to make a decree against this third party as if he were a defendant, and to grant an injunction against him and grant damages against him in this action as if he were made a party. Whether he will be unwise enough to dispute the plaintiffs' rights as regards this patent when another action is brought against him I cannot suppose. But then the Attorney-General says, Give me leave to amend, and Mr. Aston says that we ought to make such order as the Court ought to have made below, and to make such amendments as may be necessary for that purpose. But what was the course taken by the plaintiff on the trial in the Court below. In the Court below they never asked for this relief as against this third party. It is very true there was an expression by Sir Horace Davey which was relied upon, that the third party sought to be put in direct relation to the plaintiff. I do not quite understand, myself, what that meant. It is not as clear as Sir Horace Davey's expressions usually are, but these parties did not act on that, and treat it as a statement that the third party should be made a defendant. It may have been immaterial then, because the costs given to the defendant were the costs of the defendants as regards that part of the action in which the plaintiff failed, and costs were given as against the defendant as regards that part of the action on which the plaintiff succeeded. In my opinion it would be wrong, under those circumstances, and in the course which has been adopted by the plaintiffs now, to grant liberty to amend to enable the Court to give different relief against the third party than that which was asked for at the trial of the action.

Now, as to the costs. As regards the costs of the appeal, as the third parties do appear on the appeal, and as they were served with notice of appeal, there will be no difficulty in making an order against them for payment of the costs of the appeal, and in my opinion the Court has jurisdiction, having regard to Rule 54, to make them pay the costs. Therefore, as regards this part of the action, I think it would be wrong to alter the judgment. As regards the other part of the action we may, when we alter the judgment of Mr. Justice Kay, make an order against the third party as well as against the defendants for payment of the costs of the action.

Lord Justice Lindley: In substance the third parties here are the people who fought the plaintiffs, and if I had tried the case and come to the same conclusion I have done on the merits, and had been asked to amend by making the third parties defendants, I should have done it without the slightest hesitation, and I am not at all sure, if I were sitting alone on the appeal, I should not do it now. I think there is power to do it, but I will not differ from my learned brother on that point. There is a little doubt as to whether it ought to be done, and so let in the very wide terms of Order 28, Rule 1. When you see, at least apparently, that no conceivable injustice can be done—there are no merits in it, it is a mere matter of form—I should get over it. However, as I say, there has been no amendment. As to costs there is no difficulty at all. Rule 54 of Order 16 clearly gives power to make what order we think right as to costs. Now, what order is right? Those who really fought the plaintiffs and failed should pay the costs. The order will be that the third party do pay the costs here and below.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the week ended February 15 amounted to £5,346.

Digitized by Google

COMPANIES' MEETINGS.

INDIARUBBER, GUTTAPERCHA, AND TELEGRAPH WORKS, LIMITED.

The twenty-fifth ordinary general meeting of this Company was held last week at the City Terminus Hotel, Mr. S. W. Silver presiding.

The **Chairman**, in proposing the adoption of the report and the declaration of a dividend of 5 per cent., tax free, stated that the operations of the Company had expanded in the past year fully in proportion to the improvement in the general trade of the country. Their general sales had exceeded those of any previous year, showing that their works were in a condition to meet any demand that might be made upon them. Owing to the keen competition against which they had to contend, he was not in a position to state that their profit was at all in accordance with the amount of the sales; nor must they look for that unless they went into new fields and sought for new outlets such as those connected with electricity. The year's working had resulted in a net profit of £57,157, which was increased by the amount brought forward to £66,687. They recommended a dividend of 10s. a share, or 5 per cent. for the half-year, making with the dividend paid last July a return of 10 per cent. for the year; and they would carry forward £25,000. In regard to the submarine branch of their business, they had done little as compared with their resources, their staff, etc., but they were now very much better employed, and they were likely to be for months to come, and their vessels would have something to do. No profit had been taken on account of the new cables.

Mr. Abraham Scott seconded the motion.

Mr. Cochrane complained of the amount paid to the Directors for their remuneration.

In reply to questions, the **Chairman** stated that any shareholder could give notice for altering the Directors' remuneration. Their steamers had done comparatively little work during the past year. The gross profit included the profit made by them on the sale of some securities.

The motion was adopted, and the retiring Directors and Auditors were afterwards re-elected.

NEW COMPANIES REGISTERED.

Sunderland and District Electricity Supply Company, Limited. Registered by Slaughter and May, 18, Austinfriars, London, E.C. Capital £100,000, divided into 100,000 shares of £1 each, of which numbers 1 to 100 shall be founders' shares entitled to 25 per cent. of the profits. Object: to form centres in the county of Durham from which electric power may be generated or accumulated, and for distribution of the same for lighting, heating, and other purposes. The first subscribers are:

	Shares.
J. Y. Short, Sunderland	1
J. H. W. Culliford, Sunderland	1
J. Sanderson, Sunderland	1
R. Hammond, 117, Bishopsgate-street, London, E.C.	1
F. Pinkney, Sunderland	1
U. S. Barwick, Sunderland	1
W. Pinkney, Sunderland	1

There shall not be less than four nor more than nine Directors of the Company, and the first shall be appointed by the subscribers to the memorandum of association. Each Director shall hold at least £500 in the capital of the Company. The remuneration shall be the sum of £250 per annum, and one-tenth of the net profits after payment of 7 per cent. dividend per annum.

CITY NOTES.

West India and Panama Telegraph Company.—The receipts of this Company for the half-month ended February 15 show a decrease of £378, as compared with the corresponding period.

Western and Brazilian Telegraph Company.—The traffic receipts of this Company for the past week, after deducting the fifth gross earnings payable to the London Platino-Brazilian Company, were £4,506.

Telegraph Construction and Maintenance Company, Limited. Including £50,436 brought forward, the accounts of this Company for the past year show an available balance of £133,016, from which a distribution of 20 per cent. is recommended, 5 per cent. having already been paid on account. There will then remain £43,376 undivided.

London Electric Supply Corporation.—This Company has appealed to the public with an issue of £250,000 6 per cent. preference shares of £5 each. The prospectus states that the Corporation's central station at Deptford consists of freehold premises nearly four acres in extent, with a fine river frontage on which buildings are now in course of erection, and will shortly be completed. These buildings will eventually contain generating plant for 850,000 lights. At the present moment machinery for 250,000 lights is being erected, a portion of which will be in operation in the course of the next three months. The premises having been laid out with the view to further extensions, a very considerable portion of the first outlay that has been incurred is for future developments, so that all such extensions will be made at less relative cost than could otherwise be the case. The engines are of the marine type and will be of 10,000 h.p. each, with the exception of two of smaller dimensions (1,500 h.p. each). The dynamos are the well-known machines of Mr. S. Z. de Ferranti, the Corporation's engineer.

PROVISIONAL PATENTS, 1889.

FEBRUARY 11.

2375. **Improvements in the construction of telephones.** Samuel Benjamin Wilkins, 1, Parliament-square, Edinburgh.

2406. **Improvements in the mechanism of electric arc lamps.** John Roper, 2, New-street, Huddersfield. (Complete specification.)

2407. **Improvements in dynamo-electric machines.** Alexander Bernstein, 4, South-street, Finsbury, London. (Complete specification.)

FEBRUARY 12.

2472. **Improvements in secondary batteries, and plates or elements therefor.** William Lloyd Wise, 46, Lincoln's-inn-fields, London, W.C. (The Gibson Electric Co. of Europe, France.)

2476. **An improved electrical alarm.** Samuel Sudworth, 6, Estelle-road, South Hampstead, London, N.W.

2480. **Improvements in and relating to apparatus for measuring electric currents.** Henry Harris Lake, 45, Southampton-buildings, London. (Henry Henderson Cutler, United States.) (Complete specification.)

FEBRUARY 13.

2536. **Lighting, cigars, pipes, &c., by electricity.** Thomas Wm. Watson and Arthur Henry Watson, 4, Pall-mall, London, S.W.

2544. **Improvements in the form and manufacture of secondary battery frames and plates.** Arthur Douglass and Frederick Smith, 4, Danes-inn, Strand, London.

2567. **Improved means and apparatus for electrically driving vehicles.** Paul Bedford Elwell and John Kemp Starley, 17 and 18, Southampton-buildings, W.C.

FEBRUARY 14.

2614. **Improvements in electric meters.** Joseph Oulton and Joseph Edmondson, Town Hall Buildings, Halifax.

2628. **Improvements in electric contact and alarm thermometers.** Max Stuhl, Joseph Mathias Lautenschläger and Franz Lautenschläger, 142, Fleet-street, London. (Complete specification.)

2642. **Improvements in dynamo-electric machines.** George Forbes, 24, Southampton-buildings, Chancery-lane, W.C.

2646. **Improvements in apparatus or means for metering electric currents.** William Harding Scott and Laurence, Paris, and Scott, 47, Lincoln's-inn-fields, London.

FEBRUARY 15.

2694. **Improvements in apparatus for the measurement of electrical resistances.** Walter Thomas Goolden and Sydney Evershed, 46 and 47, Temple-chambers, Temple-avenue, E.C.

FEBRUARY 16.

2742. **Improvements in automatic switches for suspended "arc" lamps.** Frederick Wagg and Washington Hudson, 6, Egerton-road, Greenwich, S.E.

2748. **Improvements in telephonic switching apparatus.** Alfred Rosling Bennett, 62, St. Vincent-street, Glasgow. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1887.

7530. **Electrical transformers.** Statter. (Complete specification.) 8d.

1888.

925. **Electric measuring, &c., apparatus.** Lorrain. 1s. 8d.

1386. **Telegraph insulators.** Fowler. 8d.

3981. **Driving electrically propelled vehicles.** Hopkinson. 8d.

4489. **Holders for electrical glow lamps.** Lauckert and Haensel. 8d.

4593. **Electrical batteries.** Rawson and White. 8d.

6400. **Electrical signalling apparatus.** Dingle. 8d.

7696. **Portable incandescent electric safety lamp.** Coal. 8d.

17,905. **Rotary dynamometer.** Kasalovsky. 6d.

18,057. **Electric lamps.** Justice. (Heisler.) 8d.

18,715. **Telephones, &c.** Smith. 6d.

18,900. **Electric telegraphy.** Dewey. 8d.

NOTES.

Edison.—It is said that Edison is coming to Europe this summer.

Finland.—A long-distance telephone of 113 miles has been established in Finland.

St. Olave's.—The District Board of Works has resolved to take no action with regard to the electric light.

Shepton Mallet.—The Anglo-Bavarian Brewery at Shepton Mallet is now lighted throughout by electricity.

Rotherhithe.—The Vestry has resolved to consent to the provisional order of the Electric Supply Corporation, subject to certain objections being allowed.

South African Cables.—It is stated that the ships with the new West Coast extension cables will sail on March 8. When the lines are completed, this will give an alternative route to the Cape.

Indo-European.—The Indo-European Telegraph Company, Limited, announce that the Odessa-Constantinople cable is now repaired, thus restoring direct telegraphic communication with Constantinople and all parts of Turkey, "*via* Indo."

Society of Arts.—The paper to be read on Wednesday next, the thirteenth ordinary meeting of the session, is entitled "Arc Lamps and their Mechanism," by Prof. Silvanus P. Thompson, when Mr. W. H. Preece, F.R.S., will take the chair.

Melbourne Exhibition.—We are pleased to state that a first award, which is equal honour to a gold medal in this country, has been given to Messrs. Woodhouse and Rawson for their exhibit of electrical apparatus at the Melbourne Exhibition.

The Belgian Cables.—By order of the Belgian Government, engineers are thoroughly examining the old submarine cables between Belgium and England, in order to ascertain whether it is worth while to continue working them or whether new cables must be laid.

Melting the Ice by Electricity.—A new method of melting the ice and snow from the rails of tramways and railways is proposed by Mr. Ries, which, he thinks, will obviate both the slipping of wheels and the use of salt slush. This is to send a large current of low potential, and heat the rails sufficient to melt the ice.

The Director-General of Telegraphs.—The *Englishman* says that Sir Albert J. Leppoc-Cappel, Director-General of Telegraphs in India, has joined the firm of Pender and Company as a director. What is Pender and Company? Probably the Eastern Telegraph Company is meant, says the *Indian Engineer*, and the shareholders would hardly like the new name.

Institution of Electrical Engineers.—A students' meeting was held on Friday, February 22nd, at 8 p.m., Mr. J. Rance, jun., A.I.E.E., in the chair, when a paper was read, entitled "Ship Lighting and the aspects of Electrical Industries in the Colonies," by Mr. H. W. Handcock. The paper occupied the whole evening. A discussion upon the paper will take place on Friday, March 8th.

Bath.—It is rumoured that instead of the purely external or street lighting, that has been for some time under consideration, or rather in the act of being carried out, the good people of Bath have decided to extend the lighting, and provide for interior lighting by incandescent lamps. We have always contended that the mixed system was necessary for general lighting—the arc lights for open, and the incandescent for closed spaces.

North London Tramways.—At a rather stormy ordinary meeting, on Tuesday, of this company, the chairman of the company, in the course of his reply to some remarks, said that he hoped eventually electric cars would be adopted and that this would eventuate a dividend. It is assuring when we find directorates looking into this question of electric traction, and we hope that the surmise of Mr Carruthers Wain will be found to be correct.

New Cables.—The Eastern Extension, etc., Telegraph Company notify that the laying of their new cable between Java and Western Australia is now completed, and the line will be shortly opened for traffic. This will give the Australasian colonies the advantage of a third cable to Java, and an alternative land system *via* Perth to the overland line between Port Darwin and Adelaide, thus greatly adding to the security of telegraphic communication with Australasia.

Sweden.—Electric light and power are going ahead in Sweden. Last December a new electric light station for 3,000 16-c.p. lamps was opened in Stockholm, and now several other towns have adopted the light in their streets, among others Eskilstima and Lulea, this latter being the most northern town with the new method of lighting. An electric tramway is to be constructed at Sundswall, the motive-force being obtained from a waterfall a short distance from the town. This is the first trial of electric traction in Sweden.

Sheffield.—The central station at Sheffield consists of three 50-light Thomson-Houston machines, from which at present 110 arc lights are run. The plant has lately been increased by a Mordey alternator for distribution of incandescent lamps, which is to be started this week. This is for 600 16-c.p. lamps, and nearly the whole number are now taken up, so that the plant will have to be again increased. We are glad to learn that Mr. Tasker, the managing director, contemplates the introduction at an early date on the arc circuits of motors for supply of power.

Electrical Brakes.—The following details are given of the electrical brake of Widdifield and Button, which was tried on a heavy train on the Lehigh Valley Railroad last month. The train consisted of an eight-wheel locomotive, fifteen covered waggons, and two special carriages. Neither the special carriages nor the locomotives were braked when going from 36 to 40 miles an hour. The train was stopped at 28 seconds, after having passed over between 220 and 230 yards. This was the sharpest pull up—the ordinary stoppages for that velocity taking about 34 seconds, and the distance passed over being about 450 yards.

Sale by Auction.—As will be seen from our advertisement columns Messrs. Wheatley Kirk, Price, and Goulty will sell, on March 13, by order of the liquidators of the Electric "Sun" Lamp and Power Company, Limited, the entire contents of this company's works, which are situated at 5, Bombay-street, Bermondsey, S.E. Catalogues may be obtained of the auctioneers at their offices, 52, Queen Victoria-street. A sale is also announced through the medium of our advertisement columns of the patents, properties, and effects of the Elieson Electric Company, Limited. The date of the sale will be duly advertised.

Digitized by Google

Paris.—The *Daily News* correspondent says: "The Town Council of Paris offers a prize of £400 to the inventor of the most reliable system of computing the quantities of electric light used, and five other prizes of £50. If any system is only applicable to a continuous or to an alternate current, half the money offered will be given. The city of Paris will consider itself entitled to the full ownership of all the inventions which may gain prizes." The amount offered is not worth the consideration of anyone possessing a good meter. If such prizes as these are offered, they should be sufficiently valuable to repay the inventor. If the ownership was restricted to the city of Paris the case would be different, but as we read the communication, the inventor of the best meter gives his invention absolutely to the city, and gets in return £80, £200, or £400. We prefer to keep the meter.

Books Received.—"Practical Treatise on Industrial Electricity," including a description of Units and Measures, Batteries and Electrical Machines, Electric Lighting, Transmission of Energy and Electro-Plating, and Electro-Metallurgy and Telephony. By Messrs. E. Cadiat and L. Dubost. Third edition. Illustrated with 264 engravings. Published by Baudry and Co., 15, Rue des Saints-Pères. In regard to this book the authors say in the preface, that they have from the commencement endeavoured to render this treatise of an essentially practical character, and have eliminated all those considerations which are purely abstract. Following this programme, the third edition has been remodified in many instances, in order to retain this special feature of the work.—"Glimpses of Feverland, or a Cruise in West African Waters." By Archer P. Crouch, B.A. (Oxon), author of "On a Surf-Bound Coast." London: Sampson Low, Marston and Co.

Anglo-French Cables.—M. de Fonvielle, says the *Times* correspondent, in a forthcoming article in *Electricité*, explains the question of Anglo-French cables. The English Government had agreed to purchase them at valuation, but on the representation of France tests of conductibility and insulation were resolved upon, which terminated on Friday. The English experts applied five-minute tests, and found the cables to be in good condition, but the French experts made 15-minute tests. The results of these were much less favourable, and England has agreed to adopt this system. The price is likely, therefore, to be considerably reduced. The Dover and Calais cable is the only one in a satisfactory state. The Folkestone and Boulogne cable is unserviceable, and the other cables have several wires out of order. The reduction of the rate from 2½d. to 2d. per word will commence on April 1. M. de Fonvielle points out that the traffic last year, 13,000,000 words, is almost precisely the same as that of the French cables to Africa, which have the scarcely remunerative rate of one penny per word.

Morecambe.—Messrs. Andrews and Preece, of Bradford, have issued notices of their intention to apply to the Board of Trade for a provisional order to supply electricity for lighting purposes in Morecambe. They stated, at last week's meeting of the Local Board, that in the event of the Board not opposing their application they would fit up a central station, lay all wires underground, and supply the electric light for ordinary domestic purposes at a charge of 7d. per unit, equivalent in price to ordinary gas at 4s. per 1,000ft. For public lighting they were prepared to supply 12 2,000-c.p. arc lamps, 100 yards apart, and at an elevation of 35ft. from the ground, for £25 per lamp per annum; or for 100 nights during the season at £10 per lamp, being 10s. each lamp per night. Six lamps for the same period would cost £11 each. In winter they could substitute incandescent lamps for street lighting at the same price as for domestic purposes, the expense of a 32-candle lamp of that description being estimated at from 28s. to 30s. per year; the cost of inside fittings to be borne by the householder or owner, as in the case of gas-fittings.

The London Telegraph Clerks.—Two well-attended meetings of the clerks of the Central Telegraph Office, London, have been held, at which great dissatisfaction was expressed at the stagnation of promotion. From the statement of facts made by various speakers, it was evident that the crisis had become very serious, and was without parallel since the threatened general strike of telegraphists in 1881. At each meeting a resolution was passed pledging the London telegraphists to take combined action with their provincial brethren, and it was announced that efforts would be made to bring the grievances of the service under the notice of Parliament. It would be well, perhaps, if the telegraphists would learn a lesson. Promotion cannot be made to suit their fancies. The higher positions will neither be vacated by death nor compulsory retirement to find posts that the stream of promotion may be continuous. No doubt the telegraphists have their troubles, but in this case the cause is envy rather than anything else. The Government servant is a peculiar specimen of the *genus homo*. He fights like wildfire to get his appointment, and directly he gets it begins to grumble because it is not good enough.

Metropolitan Railway and Electricity.—On Wednesday a special general meeting of the proprietors of the Metropolitan Railway Company was held at 32, Westbourne-terrace, Paddington. Sir E W. Watkin, chairman of the company, presided, and observed that the meeting was called for the purpose of approving or disapproving two Bills proposed to be introduced to Parliament. One was promoted by the company, and the other by a friendly company. The Bill to be introduced by the Metropolitan Railway Company empowered the company to take a small piece of land for the Aylesbury extension railway, and to make a short railway, seven furlongs and one chain in length, to Chesham. The Bill authorised the Metropolitan Railway Company to run over the Aylesbury and Buckingham Railway line, and to use electricity in addition to other motive powers. The Bill promoted by the Worcester and Broom Railway Company enabled that company to construct a railway from Moreton Pinkney to Aylesbury, where the new railway will form a junction with the Aylesbury and Buckingham Railway. Resolutions approving the two Bills were carried, with power to the directors to make any alterations necessary.

Halifax.—At the last ordinary meeting of the Halifax Town Council, says the *Halifax Courier*, communications were read from Messrs. M. Holroyd Smith, England and Foster, Blakey, Emmott and Co., and J. R. Smith with respect to the establishment of the electric light in Halifax. Messrs. Blakey, Emmott and Co. asked permission to carry cables overhead or underground for the purpose of the supply. Messrs. England and Foster, writing on behalf of an intended company, to be called the Halifax Mutual Electric Light and Power Co., sought permission to take overhead wires to the various shopkeepers and across the

Digitized by Google

following streets: Broad-street, Corporation-street, Silver-street, Crown-street, Princess-street, Crossley-street, North-gate, Market-street, Southgate, and Harrison-road. The communications were referred to the Mayor (Alderman Jas. Booth), Aldermen Midgley and Pollard, and Councillors Davis, Bairstow, Binns, Oddie, Uttley, and Brear. This special committee met on Monday evening and passed the following resolution: "That permission be granted to fix wires overhead for the supply of electric light, the area and other details to be submitted by the undertakers to the Corporation for approval, the Corporation to be at liberty to purchase the plant at the end of the first seven years, or at the end of every succeeding seven years."

Better Late than Never.—The gas folks at Liverpool are bestirring themselves. One of their organs says: "However, the company are about to encounter a somewhat severe opposition in the shape of the introduction of the electric light for lighting purposes in Liverpool. To counteract this breach in their monopoly the company express their intention of conducting their works in an economic manner, and at the same time endeavour to supply cheap but good gas to the public. This, there is no doubt, is a wise resolution, and it is hoped will be thoroughly carried out, for if the public get a cheap and good gas light, they will not seek after a new and uncertain method of illumination. The chairman of the company stated to the shareholders that the consumption during the past half-year had been greater than it had been during the corresponding period of last year. It may be said for the satisfaction of those holders of shares in this particular company that although the electric light will no doubt be tried as a means of illuminating the streets of Liverpool, it will be a very, very long time, if at all, before it is extensively used for domestic services. As one speaker put it, there is plenty of room for both kinds of lights, the electric light being used as a luxury." Are we to understand from this that hitherto the works have *not* "been conducted in an economic manner"? Does this laxity prevail in many gas works? In other words, have they been conducted carelessly and uneconomically because the profits were so large that attention to details "did not matter."

Domestic Lighting.—Under the heading of "Domestic Electric Lighting in London," the *Financial News* of Monday last has a leader, the introduction of which is as follows: "A burned child dreads the fire, and the public who lost their money in the premature electric lighting boom of 1882 are rather sceptical of the financial promise of the revival which has now set in. But the collapse of the Brush mania was due to inherent engineering difficulties which have since been surmounted, and the business of electric light supply now rests upon a safe commercial basis. The recent opening of the House-to-House Company's Kensington central station, which was designed by the founders of the central station system, was looked forward to electrical circles with unusual interest. The station has been executed entirely by the House-to-House Company's own engineers, and mainly on the strength of experience obtained at Eastbourne, which is the only place where electric lighting has been accomplished from one centre throughout an extended area by means of underground mains. It is the fulfilment of these conditions—namely, the illumination of a large area by means of underground mains, as required by the permanent form of tenure under the Electric Lighting Act—which invests these installations with exceptional interest, and it is generally admitted that the Kensington station is one of the most perfect of its kind in the world. The central stations in Rome and Philadelphia are held to compare with it in excellence, and a paper instituting a comparison between these works is to be read at the Institution of Electrical Engineers at an early date."

Ohm.—In our issue of February 8th we referred to the appointment of a committee to promote the erection of a statue to Ohm. We are glad to see the *Daily News* supporting the movement as follows: "Electricians and physicists in general will be glad to hear that a committee has been formed by members of the Royal Society to assist the Munich committee in the erection of a statue to George Simon Ohm. The fundamental law so well known by the name of Ohm's law is familiar to the beginner in the study of electricity, but comparatively few advanced students know much about its discoverer. Born at Erlangen in 1789, he was in his earliest youth introduced to the mysteries of mathematical science by his father, an intelligent and self-taught blacksmith. Following up this early training, young Ohm started on his career as a teacher of mathematics and physics. He filled several educational posts, but it was not until after many years that he was appointed to a post at all proportioned to his merits. This was the professorship and rectorship of the Nürnberg Polytechnic School. In his sixty-first year he was appointed a professor in the University of Munich, where a statue is to be erected to mark the centenary of his birth. Prof. Carey Foster and Prof. John Perry are acting as secretaries in England to receive subscriptions, while Lord Rayleigh presides over the committee of the Royal Society. It is eminently fitting that some of the countrymen of Faraday and Sir William Thomson should join in this design of doing tardy honour to the memory of a great discoverer, who laid the foundations of the precise science of electricity."

The Strand.—At the last meeting of the District Board of Works, the Lighting Committee submitted a long report dealing with the electric lighting, and in the first place recommended that the application for provisional orders for same by the Electrical Power Storage Company, and also on behalf of Mr. Koeher, be not entertained. The report continued by stating that, from the number of similar applications received, it was apparent that the question of electric lighting had reached a practical stage, and had assumed more serious and immediate importance than in any previous years. The draft provisional orders as applied for were open to serious objections, they being drawn principally in the interests of the companies, and containing no effectual process for securing an adequate and continuous supply of light, and insufficient provision whereby such light could be enforced. Under their clauses considerable interference would take place in the streets, and the obligations for supply were illusory. In response to application made by the committee, the Metropolitan Electric Supply Company intimated that they recognised the importance of the objections made on behalf of the district, and that they were willing to adopt any such form of agreement as would afford a solution to the question of electric lighting and be satisfactory to consumers. The committee drew up an agreement in those terms to the last-named company, and recommended it to the Board for adoption. The agreement limited the interference with the thoroughfares to the pavements or the roadway near the pavements, and secured that that interference should be made at convenient times.

Digitized by Google

The recommendation, after a few remarks, was agreed to, the adoption being moved by Mr. Warne.

Bradford.—Those of our readers who know Bradford will remember the Midland Railway Station. The Bradford Corporation's central electric lighting station is situated on what was a piece of waste ground near here, a little way down the road to the left. It is a handsome solid stone building, with boiler-house and chimney shaft adjoining. The whole of the machinery is being prepared by Messrs. Siemens Bros., and the foundations are ready to receive the engines, which will be delivered shortly. The supply being undertaken by the Corporation, they will not be able, nor do they wish, to pick and choose their customers. All comers will be supplied, and current only—or rather electric energy—will be charged for; the consumers will be able to use the current in any way they please inside their buildings for light, heat, power, or for charging accumulators. Full and continued tests will be made to settle upon a reliable meter. This service necessitates a direct-current system, and this will be adhered to in all extensions of the system, and will enable the subsidiary stations to be linked together. The mains will all be laid underground. A low-tension system will be adopted at first, and the mains will vary in pressure to compensate for loss by resistance, to bring the distributing wires to the same pressure. As the demand increases, high-pressure mains may be laid to outlying districts, with battery or other practical means of direct-current transformers. The electrical work is not in a forward enough state for much to be said at present, and it is probable, when this is the case, that details will be communicated to the Institution by Mr. J. N. Shoolbred, consulting engineer to the Corporation.

Deptford.—On Wednesday evening, the 20th ult., a meeting was held, under the presidency of Mr. E. J. Wright, at Deptford, to consider the question of the supply of electricity in the district. There was a fairly good attendance. The chairman said that the Electric Supply Corporation had erected works at Deptford, and were applying for a provisional order from the Board of Trade, the question of which will come before the Greenwich Board of Works at the next meeting. Mr. Sparkes, one of the engineers of the company, delivered a statement as to what the company are able to do. He said the electric wires would be in pipes, something like gas pipes, and there would be a wire into the house, and a meter, and the occupier would be able to use the electricity for motive power or for lighting. The company, however, would have nothing to do inside the house. They were makers of the electricity, and nothing more, and had no desire to become a monopoly. They did not propose to supply lighting for the streets unless it was asked for. The cost to have one light would be about 45s., but the company did not supply for less than 25 lights, with a minimum charge of £20, but when they started at Deptford they would probably be able to reduce this minimum, and hoped in time to bring the price below that of gas. After some discussion, in which the chief topic was the disturbance of the roads, it was resolved: "That whilst approving in principle of the extension of electric lighting, to ask the Greenwich Board of Works to deal with the issuing of a provisional order in such a sense as to prevent monopoly, and avoid undue disturbance to the highways of the district, to guard the interests of the ratepayers in regard to prices and profits, and to provide for the compulsory supply of electricity by the company to the ratepayers on fair and reasonable terms."

Electric Stamp.—A company has been formed during the week to manufacture, and sell or hire, the Electric Time and Date Stamp, to which we referred a few weeks ago. It is believed that this stamp will be very useful in many offices, where the time of receiving goods, or sending out letters or parcels, is of importance, or in such cases as the time of the despatch of trains, tramcars, and omnibuses, or of the despatch of messages. The stamp was originally invented for dating telegrams, and for this purpose, if it can be made thoroughly reliable in its clock action, it should prove extremely advantageous. The electric stamp has been tested by the Post Office authorities, and an order for stamps to suit this purpose has been given. Some of the tramway companies have also tried them and express satisfaction with the result, giving orders for stamps for use on their lines. With a simple electrical connection, these stamps might be used so that trains might automatically register the time of passing upon a record strip in the signalman's office; and a similar electrical arrangement could be adopted for night watchmen, policemen, and others, where the time of their presence is of importance. In substance, the electric stamp is a small box with a lever handle on top for giving a blow on the paper to be stamped. Inside is simply a series of wheels properly geared, having on their circumferences figures to represent the hours, days, and minutes. These are moved forward with a step-by-step action by an electromagnet. The magnet is excited by a current from a battery, the circuit of which is closed once every minute by contacts on a clock. One clock can control a series of stamps, or a series of clocks can be controlled from one master clock, as desired. There is little doubt that the stamp may prove very useful in the departments for which it is designed.

The London Vestries.—The Committee of Works reported, at the last meeting of the Holborn District Board, that they had had under consideration the applications of the London Electric Supply Corporation and the Metropolitan Electric Supply Company for permission to apply to the Board of Trade for provisional orders. They recommended that permission be given. The report was adopted. Permission was also given to the House-to-House Electric Light Supply Company to apply to the Board of Trade for a license to erect works and supply electricity within portions of the district.—The Kensington Vestry has received the following communication from the Kensington Electric Lighting Company: "Your attention has no doubt been called to the fact that we are making arrangements to fix some arc lamps along the portions of the main road between De Vere-gardens and Queen's-gate, which is lit on one side by the Westminster Vestry. If this work is carried out, we would like to suggest that to make the trial more complete, and for the information of the Vestry, it would be a good thing to light some lamps in your district as well. If the Vestry approve of this proposal, we shall be glad to go into full details with you in conjunction with the Westminster Vestry. The arrangement we are making is that the work shall be done and the light supplied for a period of one month free of charge. If at the end of that time the Vestry wish to have either the lamps in question continued or other lamps supplied, we will then be in a position to give an exact estimate of the cost of fixing and supplying. The Vestry would not be bound to continue the lighting after the end of the trial." It was resolved that the offer be accepted, the work to be carried out to the satisfaction of

Digitized by Google

the surveyor.—St. Martin's-in-the Field's Vestry has passed a resolution approving the application of the London Electric Supply Company for a provisional order.

The City Lighting.—At a special meeting of the City Commission of Sewers on Tuesday at Guildhall, the Streets Committee reported the conditions upon which proposals for lighting by electricity should be advertised for. The main thoroughfares and public streets of the entire area of the City are to be lighted, and for convenience divided into three districts, and the contractors are at liberty to tender for either one or two districts, or the whole City. The three districts are denominated the west, the central and the east, and the positions of the arc and glow lamps, as well as those of the existing gas lamps, are to be expressly indicated, and, in addition, the positions of the mains and service pipes. So soon as the main thoroughfares have been lighted, the contractor must proceed, when called upon, to light the other public ways. The whole of the lamps are to be efficiently lighted nightly from sunset to sunrise, and when otherwise necessary; but the existing system of gas lighting is in no way to be interfered with, in case gas lamps may have to be reverted to. All mains and service conductors are to be laid beneath the public way, and in no case are streets to be broken up without notice, or telegraph and telephone wires interfered with. So far as the Commission are able to do so, they will grant to the contractor the exclusive right of supplying electricity for private purposes within the district, and the consumers are to be charged either by meter or agreement at a fixed rate. The duration of the contract is to be 21 years, subject to determination in certain contingencies, and it is provided that if the profits arising from the contract exceed a cumulative dividend of 10 per cent. per annum on the capital invested, the excess is to be divided equally between the contractor and consumer by the reduction of the charges. Power is reserved to the Commissioners to acquire the undertaking and works by purchase at the end of 21 years. After some discussion the adoption of the report was carried by a large majority, and the conditions of tendering were approved.

Electric Blow-Pipe.—A new method of electric welding, or electric blowpipe, as it may be termed, is proposed by Prof. Sheldon, of Harvard, in the *Scientific American.* The peculiar behaviour of the arc in a magnetic field is employed in this process. A dynamic attraction or repulsion occurs when a pole of a magnet is brought near an arc light, and the arc is apparently blown outwards in the form of a flame, terminating in an intensely luminous point. The heat at this point is intense, and suffices to melt any metal. A piece of No. 14 copper wire held at the apex melts instantly. This extreme heat in such a convenient form can be the means of bringing electro welding within the reach of all shops where arc lamps are employed for illumination. By a mere nominal alteration the lamp may be made to perform the double function of illumination and welding. To attain this end, a straight electro-magnet wound with coarse wire is only necessary. This is placed with one end towards the arc, and may be fixed in one position (to be determined by experiment, and depending upon the direction of the desired point of the arc), or made movable in a horizontal plane on a level with the arc. The two terminals of the magnet coil are inserted anywhere in the main circuit, or, if found necessary, may be shunted from the same. The connections once made, can remain undisturbed, and, without influencing the main line, the lamp performs its two functions. In the employment of the arc for electro welding, the operator must, of course, wear coloured glasses for the protection of the eyes. Care must be used in the selection of these, for some of the colouring matter used (especially in blue and red glasses) absorbs the light given out at the apex of the arc, and this would be detrimental to fine work. The electric arc, when in a strong magnetic field, exhibits another peculiarity. It is known that if a circuit, traversed by a strong current, be broken under ordinary circumstances, a moderate spark will ensue, accompanied by a snap similar to that given by a toy cap when exploded. If, however, the break be made in a strong magnetic field, an extremely large spark follows, accompanied by a peculiarly sibilant report, as intense as that of a pistol. The effect is very startling when unexpectedly made.

Manchester.—The proposal to establish a central electric light station in Manchester is now, we believe, well within view of possibility. The gas works of Manchester, it may be remembered, are owned by the Corporation, and this fact naturally causes complex views of the new proposal on the part of the members of the Corporation. The Manchester Edison-Swan Company were open to obtain a provisional order for themselves, but they judged it to be wiser to endeavour to work with the Council. On the proposal being submitted, the Corporation signified that they must have assurance that a demand really existed for the electric light, and stipulated that signed requests for a supply of 8,000 incandescent lamps must first be obtained. A canvass of the proposed district has therefore been made, with very encouraging results. Up to the present, the company have received requests for some 7,000 lamps, with numerous others in blank not committing the persons to the number required—making, probably, a total of some 10,000 or so. When the canvass is finished, these signatures will be submitted to the Corporation, who then, it is hoped, will work together with the proposers of the new light. A fresh call on the shareholders, to the extent of £2 a share as required, would be made for the purpose of carrying on this work. The area proposed to be lighted is the busiest centre of the town, and, as land is expensive here, the station would not be directly in this district, but some little distance away. The system, as far as has been arranged, will be the alternating transformer system, with underground mains. Estimates have been gone into by the company to ascertain the approximate cost, but nothing absolutely definite is yet arranged. The station would be at first for 10,000 lights, one would be extended, or similar ones established in other parts of the town. The scheme has been started and would be carried out by the Manchester Edison-Swan Company. The company of the name of the Manchester Electric Supply Company have nothing to do with the proposed station (as has sometimes been thought), being at present simply the branch office of Messrs. Holmes and Vaudrey, of Liverpool. This will be the first practical attempt of the Manchester Edison-Swan Company to distribute electricity on any scale. The small station with accumulators once established there, was for the theatre alone, and this has been discontinued for some time, leaving the entire work of the company to consist at present of house and factory installations, of which a very large amount has been done in the district. We shall await with interest the result of their present action in promoting a central station for Manchester.

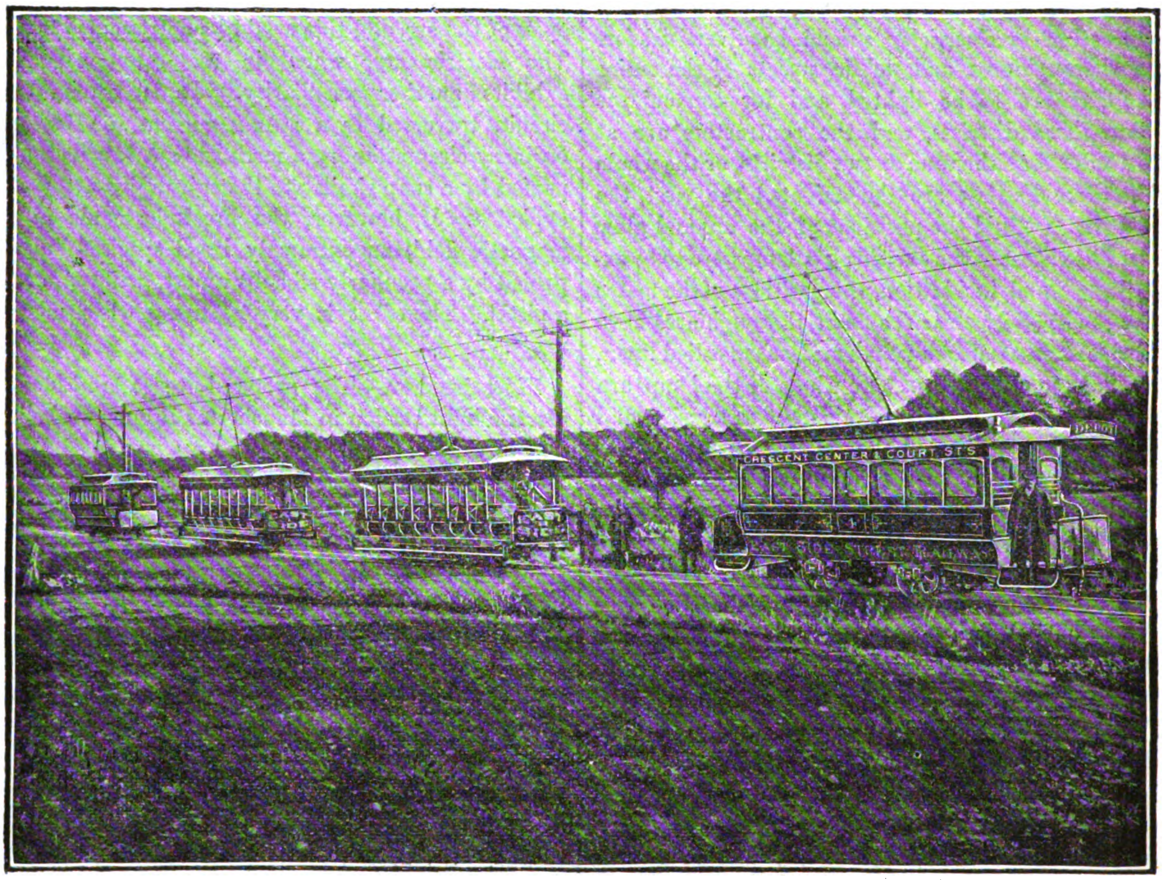
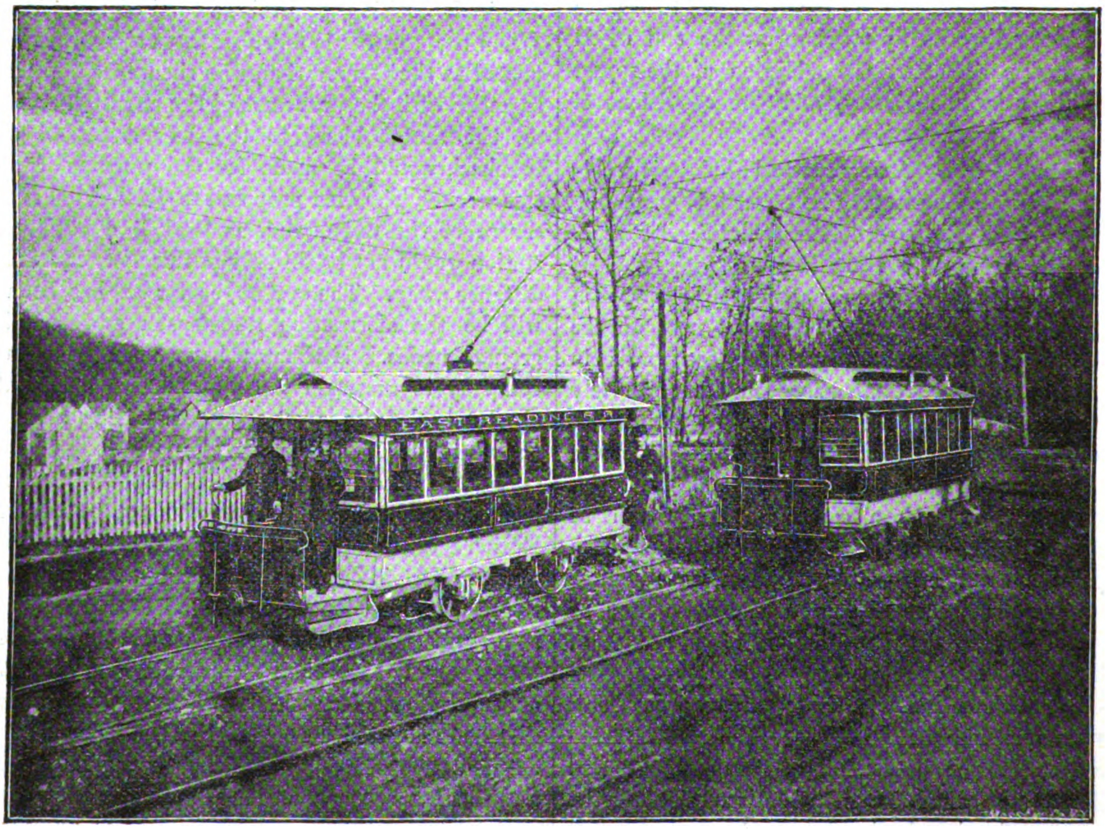
ELECTRIC TRACTION IN AMERICA.

THE SPRAGUE SYSTEM AT BROCKTON, READING, AND WILMINGTON.

While we in England are laboriously talking about introducing electric traction in various directions, our American cousins are engaged in less talking and quicker action. A short time since we received further information as to the later doings of the Sprague Company in various parts of America, and we notice that our American contemporary, the *Electrical World*, has been also discussing this subject. The illustrations which we give herewith, and for which we are indebted to the Sprague Company, show several views taken from recent photographs of electric railways which have been installed by this company.



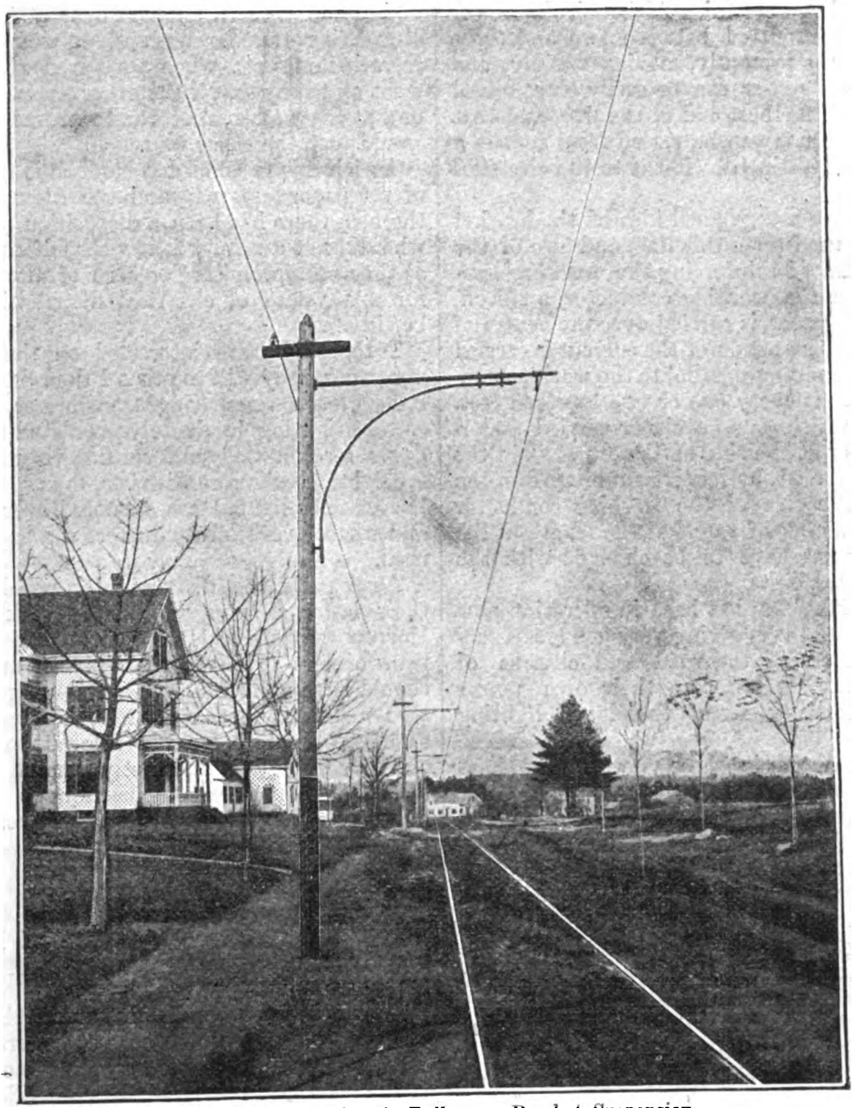
I.—Sprague Electric Railway at Brockton. Bunching the Cars.



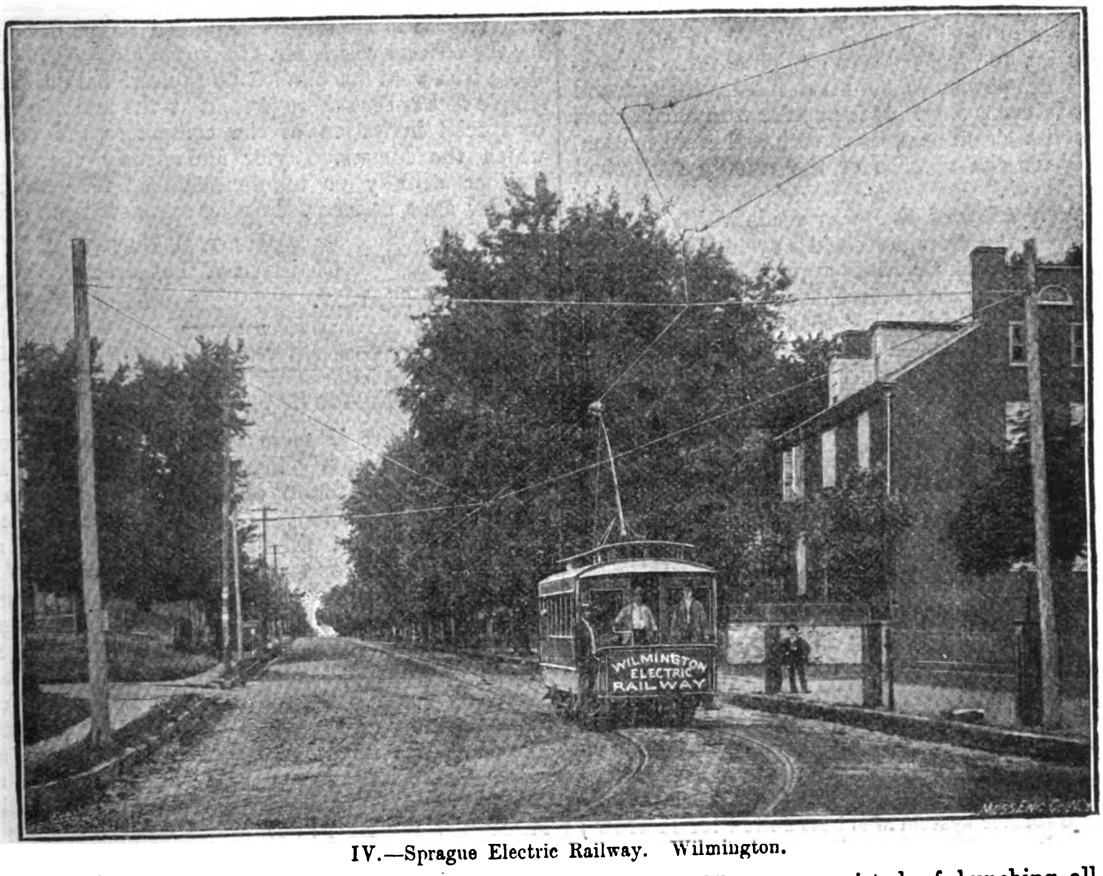
III.—Sprague Electric Railway. Reading, Pa.

The first two engravings are of views on the East Side Electric Railway of Brockton, Mass., of which Mr. Albert F. Small is president. This road extends over a circuit of

Digitized by Google



II.—Sprague Electric Railway. Bracket Suspension.



IV.—Sprague Electric Railway. Wilmington.

about four miles in length, operating four cars. The first engraving represents a test which was recently made upon the railroad, and was taken from a photograph made upon the spot. The test consisted of bunching all the cars of the company at a point on the road farthest distant from the power-house, and in starting them all up at once.

Digitized by Google

The test was perfectly successful. Although the power for all the cars was transmitted between two and three miles, the cars started up promptly, moving rapidly, and showing that the entire power can be easily transmitted and applied even at the farthest end of the line, and that the load upon the dynamos can be varied from zero to a maximum without any resulting detriment to the electrical apparatus.

The second view gives a very good idea of the bracket method of suspension used upon this line, and also of the Sprague overhead system of reinforcing the working conductor. By this system the working conductor, a silicon-bronze wire of small diameter, is carried over the centre of the track, while the greater portion of the current is carried upon a main conductor running parallel to the working conductor, and connected to it every one or two hundred feet. This main conductor, which can be either carried underground in a subway, or at the side of the street as in the view, can also be reinforced by feeders running from the main power station. The size of the working conductor is independent of the number of cars and the length of the line, and therefore does not have to be changed with the alteration of any of these points.

This electric road at Brockton has been in operation now for about four months, and it is giving very good satisfaction to both the directors of the road and citizens of Brockton. The company do not own their own power station, but hire electricity from the local lighting company.

The second road illustrated in these views is the East Reading Railway, of Reading, Pa. This view gives a very good idea of the method of overhead wiring for a turn-out. The road is a single track road, extending over about two miles, and is said to be giving very good satisfaction to the president and directors of the road. The road has been in operation about two months.

The fourth engraving is a view of an electric car on the Wilmington City Railway, which has been in operation upon the Sprague system for about eight months. This road has given such great satisfaction that the directors of the road have ordered an additional number of cars.

In the letter to the Sprague Company, the president of the road, Mr. William Canby, says: "From the practical experience we pronounce your system a complete success. We consider it by all odds the most economical mode of running street cars in suburban districts, or in any place where permission to erect poles can be obtained. In comparison with horse-power, we find it decidedly cheaper and more efficient in every way. It is popular with our patrons on account of its cleanliness, its smooth and rapid motion, and especially for the absence of the usually overtasked and labouring horse."

These are only a few of the many roads which are now in operation upon the Sprague electric system in all parts of America. The number of Sprague electric roads is rapidly increasing, new contracts being closed every day, one of the latest of which being that for Atlantic City, New Jersey, made by the Pennsylvania Railroad Company, who own the system of railways in that city.

CORRESPONDENCE.

HARROW LIGHTING.

To the Editor of The Electrical Engineer.

Sir,—The form of your report on the meeting held at Harrow would lead your readers to suppose that it was absolutely verbatim, at any rate sufficiently so to correctly represent what passed at the meeting. I find, however, on reading it over, that there are important omissions. For instance, after stating that I explained the two well-known methods of distributing electricity by alternating transformers and by battery transformers, I am made to say simply that the former system was best suited for Harrow; whereas I took considerable pains to point out that, although as a rule I had a preference for the battery transformer system, yet on account of the peculiar distribution of the Harrow lighting in a small number of large houses distributed over a considerable area, the alternating transformer system was at its very best, as regards first cost, when compared with the other; but I went on to say that if the other site which had been pointed out at the west end of the town was adopted, the balance would turn the other way.

I wish this to be clearly understood, as since the reading of my paper last year, and the discussion which followed thereon, there has been a disposition on the part of those who did not carefully follow that discussion to consider me as the uncompromising opposer of alternating transformers for any system of electrical distribution, wherever it may be situated.

If those who are interested on the subject will turn to my paper, they will see that I then dealt with the unsuitability of the alternating transformer system for central station lighting in densely-populated towns—such as London. I acknowledged from the very first its great utility for lighting suburban districts, towns, or villages, where the houses to be lighted are scattered over a considerable area, and where overhead conductors can be wholly or partially used.

As regards the discrepancies which Messrs. Taylor, in their letter to you, appear to think exist between my Harrow estimate and the general estimate for alternating transformers given in the body of my paper last year, I should have no difficulty in reconciling the figures to those who understand such matters, bearing in mind that the smaller estimate is for 144 kilowatt plant only, and that the very important and costly item of boilers, water-tanks, feed supply, and steam connections is omitted, as we were informed that these could be taken over on rental from the water works company.—Yours, etc.,

R. E. Crompton.

ELECTRIC LIGHTING IN HARROW.

To the Editor of The Electrical Engineer.

Sir,—Mr. Crompton is doubtless well able to defend his position as against the attacks of Messrs. Taylor.

I believe those gentlemen were the only persons present at the meeting at Harrow who regarded Mr. Crompton's clear and business-like statements as a "fiasco." Be that as it may, I can neither take to myself the blame which they impute to me for the supposed fiasco, nor the credit for the success which Mr. Crompton attained in the eyes of those who were not blinded by professional jealousy. The simple fact is that those present at the meeting were there by special invitation of the committee, the existence of which the Messrs. Taylor audaciously charge me with "either wilfully or unintentionally" forgetting, and of which I am a member. Further comment is unnecessary.—Yours, etc.,

Robt. B. Hayward,
Chairman of the Harrow Local Board.

February 26, 1889.

UNDERGROUND MAINS.

To the Editor of the Electrical Engineer.

Sir,—As there is some misapprehension caused by an advertisement recently inserted in your paper as to the West Brompton station of the House-to-House Electric Supply Company, Limited (called by them the Kensington station), I trust you will allow me, on behalf of my company, the Kensington and Knightsbridge Electric Lighting Company, Limited, to furnish you with a statement of the work done by the respective companies in Kensington.

My company (the Kensington and Knightsbridge Electric Lighting Company, Limited) commenced in 1887 to supply electricity under a license from the Board of Trade in a limited area round the works situated at Kensington Court. The plant was furnished by Messrs. Crompton and Co., Limited, who acted as the engineers, and devised a system of underground mains which gives complete satisfaction. Thereupon my Board decided to enlarge their operations and apply for an extended area, a portion of which has since been granted. In consequence, electricity is now supplied through several mains at a radius of three-quarters of a mile, and in a short time the

Digitized by Google

distance will be considerably extended. There will, however, be no necessity in this district to carry the current more than two miles, as the company have a station in a central position at Knightsbridge, which is now in course of completion.

From the mains already laid, shops, houses, and public buildings (including the St. Mary Abbotts parish church) have been supplied with the current night and day constantly with the utmost satisfaction.

As to the House-to-House Electric Supply Company, Limited, I am, after enquiring a fortnight since, in a position to state that in spite of all their protestations and advertisements, they have not to my knowledge supplied any current to houses or shops within the district of Kensington. Further, I am unable to see how they can claim to be the first company in London to supply an extended area through underground mains inasmuch as they possess no license from the Board of Trade to break up the streets. I trust you will insert this in your next issue, as my company is suffering from the confusion which has arisen from the House-to-House Electric Supply Company adopting the name of the "Kensington Station" for their station at West Brompton, and making the claims above referred to.—Yours, etc.,

R. Erskine, Secretary.

High-street, Kensington, Feb. 28, 1889.

THE ELECTRIC LIGHT IN BARNET.

To the Editor of The Electrical Engineer.

Sir,—In pioneering the system of incandescence lamps in series for street lighting at High Barnet, we have had to contend with great opposition and unusual difficulties, but even taking into account the stoppage of the light owing to uncontrollable causes, such as wilful damage to our wires, etc., the whole of the failures during the past six months and severe winter weather has barely exceeded 1 per cent. of the total hours of lighting, and this we submit is very encouraging, and is, we believe, the best record of town lighting.

In the opinion of many qualified engineers who have visited Barnet, the system of street lighting by 32-c.p. incandescence lamps is a success.—Yours, etc.,

Henry F. Joel and Co.

City Electric Light Works, 31, Wilson-street, Finsbury, London, E.C., and Melbourne, Feb. 27, 1889.

RECENTLY PATENTED IMPROVEMENTS IN SECONDARY BATTERIES.

We are in receipt of the following interesting statement from President D. H. Bates, of the Electrical Accumulator Company: "The manufacture of secondary batteries in the United States is increasing rapidly with the growing demand for this form of apparatus in electric lighting and applications of power. The question as to whether or not the broad features of improvement attributed and patented to Faure are to be secured to his assignees, the Electrical Accumulator Company, is now in the hands of Judge Cox, and a decision will be rendered very shortly. The recent decision in the United States Supreme Court in the Bate refrigerating case has eliminated the only defence having any apparent merit. Faure's invention, as is well understood, was the application of an active material to a plate or support prior to immersion in the battery fluid. Subsequent inventors modified the nature and form of the support plate and the manner of combining this support plate and the active material. Among batteries now obtainable, whether at the hands of authorised manufacturers or infringers, are those having a support plate of lead, others having a support plate of lead and antimony with perhaps a little mercury added; and as regards the form of plate, the key-lock principle is applied to all. Perforations having a smaller diameter at or near the centre of the plate meet with the greatest success; others have cells or perforations, the greatest diameter being at points intermediate between the surfaces of the plate. Your patent record shows that the specific modifications mentioned were long since contemplated and patented by an English inventor.

"The result of the recent interference between the application of John S. Sellon, of Hatton-garden, England, and Edmond Julien, assignor to the Julien Electric Company, is shown by the issue to the Electrical Accumulator Company (Sellon's assignees) of patent No. 396,958, dated Janury 29, 1889, claim 2 being the issue in interference, to wit: 'In a secondary battery a plate, element, or support containing lead and antimony in combination with an active material.' Recent publications emanating from Julien's assignees give an impression widely at variance from the issue of this patent shows to be the facts. The language of the technical expert of the Patent Office, not referred to in the publication of the Julien Company, shows what the facts really are: 'If Sellon was the first to use plates formed of lead and antimony, or two or more metals, of which lead and antimony are essential, I can see no good reason why he should not claim his invention in such broad terms as would prevent its being pirated by the addition of a small percentage of some other metal. The addition of a small proportion of zinc, tin, or bismuth, all of which are well-known constituents of type metals, which are essentially alloys of lead and antimony, would avoid any patent he might obtain, unless he is protected by some such claim as the one in interference, and the purpose of the claim seems to be to protect him from just this danger. Julien's claim is included in and subordinated by the claim of Sellon, for the reason that it is directed to an alloy of which lead and antimony are essential ingredients.' The issue of this patent gives Sellon's assignees, the Electrical Accumulator Company, the control of the battery employing an alloy plate, whether the present suit based upon the Faure patent now in the judge's hands, and upon which a decision may be expected within a short time, is favourable or unfavourable. The public may therefore take warning at this time against further infringement on patented rights; for, if upon the decision being rendered against the manufacturers such manufacturer should be insolvent or irresponsible, resort will doubtless be had to consumers or users for an accounting and for damages.

"A second very important patent granted on the same date to the assignees of Sellon for improvements in secondary batteries, No. 396,770, is also of sufficient importance to merit special attention. This is intended to cover and covers a special form of perforated plate, such as is used by the Gibson Electric Company, and such as is shown in the recent modification of Faure's invention attributed to Anthony Reckenzaun. The Gibson battery makes more or less successful use of a perforated plate produced by piercing a sheet of lead with a series of perforations in such a manner that the openings at the surface of the plate are smaller than the diameter of the perforation at one or more points intermediate the surfaces. The claims of this patent, as will be seen from the example given, cover this construction. For instance: 'In a secondary battery a plate, element, or support, having cells, perforations, or receptacles, the diameter of which at or near one or both poles of the major axis is less than the diameter at one or more points intermediate said poles.' This gives the assignees of Sellon a practical control of the form of battery manufactured by the Gibson Company, the invention of Sellon, as shown by his English patent, having been perfected long before the construction was adopted by Gibson.

"The third patent covers the construction adopted by FitzGerald Jones in England when they were manufacturing batteries for experimental or exhibition purposes. The FitzGerald-Jones plan was to mould a solid peroxide plate, and attach a framework of celluloid to the edges and parts of the surface thereof. On the inside of this frame, between the frame and the peroxide plate, was a thin strip of platinum; but this construction was contemplated and perfected by Sellon long prior to the time of its adoption by FitzGerald-Jones. This third patent, No. 396,769, was issued on the same date as the others above referred to. One claim reads: 'In a battery, a support or terminal containing a practically inoxidisable material, combined with a conductor of platinum and a mechanically applied active material substantially as described.'

"These three patents are all believed to be valid. If so, their ownership places the Electrical Accumulator Company in position to control the accumulator or secondary battery industry of the Faure patent."—*Electrical World.*

Similarity of Address.—Messrs. Arthur B. Gill and Co. write, asking us to call attention to the fact that mistakes have arisen owing to their works being at No. 4, while a sale is to take place at No. 5, Bombay-street. There are a good many people, unfortunately, who jump at conclusions, and two works of a like nature next door to each other always leads to confusion. However, we are glad to be informed that Messrs. Gill and Co. are very busy; they are not interested in the Sun Electric Light Co., whose affairs have given rise to these troubles, and care should be taken to note the difference of title and address.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of Mr. E. Graves, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. Wollaston, M.D., F.R.S., *and* Sir Humphry Davy, F.R.S. *The portraits of* Prof. D. E. Hughes, F.R.S., *and of* Dr. J. Hopkinson, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

THE STOCK EXCHANGE.

Did any reader ever see the sensitive plant? If so, they will know how it answers every touch. The Stock Exchange is a sensitive plant of another kind, answering every touch, and by its actions writing history sometimes in a most uncomfortable manner. Like the sensitive plant, the Stock Exchange is unable to distinguish between friend and foe, and so it treats all alike. It may be almost taken for granted that its actions are automatic, and guiltless of the merest soupçon of reason. At one moment there is a panic, the cause of which is hidden from ordinary eyes, at another time the most unreasoning confidence is shown in concerns that to the ordinary intellect appear to be as rotten as the apples of Sodom. Of course, the whole meaning of this state of things lies in the fact that the Stock Exchange is purely and simply a gambling hell, and that its sole end and aim is to pick up the crumbs which fall at every turn of the market. A large number of shareholders in most bona fide concerns are investors as distinguished from speculators. The action of the Stock Exchange generally tells somewhat heavily against investors, for, with the proverbial cussedness of things mundane, the investor usually wants to realise when the market is against him. However, we have no wish to analyse the inner workings of Stock Exchange matters, and certainly we have no desire to seek for the consciences of its habitués. The Stock Exchange has occasional fits of compunction, for we all know that

"When the devil was ill, the devil a monk would be;
When the devil was well, the devil a monk was he."

And for a time something is to be done. The fit passes away and promotion and speculation are as rampant as ever, and so the world goes on. It will be seen that we believe the Stock Exchange and all connected therewith altogether out of the commercial sphere of salvation.

It may be well just at the present moment to look from the investor's point of view at the position of the electrical companies engaged in litigation. Suppose, in the first place, that success still attends the Edison-Swan combination in the Lords' appeal. The Brush Company will then be solely dependent upon its business outside lamp-making to produce a dividend to its shareholders. The profits hitherto obtained and paid—leaving out of consideration the speculative era—have been made from business other than lamp-making, and there is every indication that this, what may be termed the legitimate business of the company, will increase and multiply. The profits earned should increase with the increase of business, and if heretofore it has been possible to earn a dividend, it should year by year be easier to earn a similar or a larger dividend. The shares have recently touched par, and are now but little below it. Why they should have

Digitized by Google

dropped may be from fear of law costs, but at the very worst these will not affect the permanent position of the company. The position of the Edison-Swan combination is far different. The shares in this company have long been considerably below par. According to the reports issued to the shareholders the position of the company has gradually become better, but so far dividends have been unknown, the profits having been put to a reserve fund in regard to the contingencies which might arise out of the litigation. The obtaining of a virtual monopoly would ensure a dividend if there is no further litigation in other quarters. Hence in our opinion, while the Brush Company is fully able to earn dividends from sources independent of lamp-making, the Edison-Swan combination necessarily looks to its manufacture of lamps as the principal source of income. This is as it should be, the speciality of the former company being its dynamos and heavy electrical apparatus, that of the latter its lamps. In the one case lamps are subsidiary, in the other heavy apparatus is subsidiary. No doubt the Brush, and, indeed, many other companies, would like to get the profit upon the lamps they could in the ordinary course of business sell, but in the case we have assumed that is not to be. There is the opposite result to be considered when the Edison-Swan combination find their monopoly destroyed. If this should be the case, it would have to take its chance in the competition against a number oi manufacturers who would commence to manufacture. In such competition they have immense advantages. In the first place, if they play their cards correctly, they should have a hold of a great majority of the purchasing public. If every attempt is made to meet the demands of purchasers to produce the best class of goods at a fairly cheap rate, any competitor would find it difficult to get much of a footing in the market. But, of course, the company would not be in the good position it would if the monopoly is determined. In the one case, we say good dividends ought, with good management, to be a certainty; in the other, they would be reduced to a probability.

It would be interesting to know something as to the number of shares changing hands in various kinds of companies. Is the number greater when the concern is flourishing and paying, and what is the average length of time shares in such companies are held? We presume that these shares fall more into the hands of investors, and do not change hands so frequently as in the case of companies where the sole profits are due to the rise and fall of the market. In the latter case, some shares are usually held during long periods; for a man not compelled to sell at any particular moment waits and watches for the good time coming. Meanwhile, the Stock Exchange takes advantage of every rumour, and makes its bargains accordingly. Its actions should be viewed with caution, and investors should not be in a great hurry to follow its lead, and, in fact, not to follow at all till after due consideration and investigation. The two companies specifically referred to have made some provision for awkward contingencies, and we think the sketch we have given of their position in any case is fairly accurate.

ELECTRICAL ENGINEERS AND ACCIDENT INSURANCE.

It is well known that the name "electrical engineer" has hitherto conferred upon its owner the proud privilege of paying £6. 5s. per year premium on an insurance of £1,000 in the Accident Insurance Company, instead of a premium of £4, which is the ordinary rate. One or two of the minor companies have not strictly adhered to this rule, and we now have to chronicle the giving way of the principal English company. A short since one of the local agents of the company, Mr. Maynard, station-master at Bromley, Kent, had occasion to send in a form of proposal from Mr. Schiassi, an electrical engineer. The result was an intimation that the premium would be as above stated, but, after a good deal of correspondence between these parties and the head office, Mr. Vian has given way, and in future all electrical engineers not directly engaged in the working of the machinery—such, for example, as linemen, foremen, superintendents, etc. —can be insured at the ordinary rate. Many of our readers will remember a discussion on this very subject some years ago, initiated by Mr. Dowsing, of Messrs. Crompton and Co. At that time it was pointed out that while some electrical engineers might well come under the "hazardous risks," there were a large number who no more hazarded their lives or their limbs than the parson or the schoolmaster. The addition of more than 50 per cent. to the premium is a consideration not likely to be overlooked by men who are not overpaid, and the gentlemen who have fought the fight to success must be congratulated upon the result.

ELECTRICAL MEASUREMENT.*

BY PROFS. W. E. AYRTON, F.R.S., AND J. PERRY, F.R.S.

(*Verbatim report of the abstract of the Paper given by Prof. Ayrton at the meeting.*)

The rapid development of electricity for commercial and industrial purposes makes it quite unnecessary for me to give any preface as to the importance of methods for the exact determination of the values of current and potential differences, and of the making of portable and simple apparatus to enable practical men to measure quickly and accurately the quantities that are so necessary to be measured for determining the value of any particular distribution of electricity.

* Paper read at the Physical Society, February 23, 1889. Prof. Reinold, F.R.S., in the chair.

Digitized by Google

It is well known that when a galvanometer is used for measuring current simply, the alteration of its resistance, whether by change of temperature in the room, or by heating due to the passage of the current, is of no consequence; whereas when the galvanometer is used as a voltmeter for measuring potential differences, the change of resistance, whether due to change of temperature of the room, or to heating of the instrument by the passage of the current, is all important because the resistance due to the rise of temperature diminishes the sensibility of the instrument. For that reason Prof. Perry and I attempted to solve this question some years ago, with reference specially to our own magnifying spring voltmeter, and to determine what was the proper metal to wind it with, and what was the proper law according to which the thickness of the wire should vary as the centre was departed from, in order that the heating error should be a minimum—that is, the error due to the maintenance of the P.D. at the terminals of the voltmeter; and the results were communicated to this society in 1885. For the purpose of making the calculations in that paper, we were compelled to assume a fairly simple law for the variation of the effect of a coil as you departed from the centre, and also of a fairly simple law for the connection between the thickness of the covered wire and the thickness of the copper or uncovered conductor. The calculation was difficult enough indeed, even when simple laws for these variables were assumed. The results obtained were that, in order to make the voltmeter such that there should be the least probable variation of resistance when a given potential was maintained, the instrument should be wound with copper, and not, as was usually supposed to be right, to wind it with german silver, and further, that the diameter, in our particular instrument, of the uncovered wire should vary according to the distance from the centre raised to a certain power—viz., ·42. This result, as a matter of fact, has been followed by the makers of our instruments, but as, of course, it would be too difficult for them to make the diameter of the copper wire vary in each layer, they have used only three, or in some cases four, gauges for winding a voltmeter.

Since 1885, the metal platinoid has been brought before our notice; this has a temperature coefficient less than half that of german silver. Experiments have also been made at the Central Institution by the first year's students on the temperature coefficient of phosphor-bronze, and they find that the variation of resistance by temperature of phosphor-bronze, a metal of very much lower specific resistance than german silver or platinoid, is only ·082 per degree C. Phosphor-bronze wire increases its resistance by about ·082 per cent. per degree C., and has a resistance per cubic centimetre at 0deg. C. of about 9·7 microhms. Therefore, the question has now to be considered by taking platinoid and phosphor-bronze into account.

The whole subject may be treated in a far simpler way than we treated it in our paper of 1885, if the same gauge of wire is used throughout the instrument. That is not quite right, because, as a matter of fact, we use three gauges in the actual voltmeters. At that time we assumed the thickness of the insulating covering to increase proportionately with the diameter of the metal. That is not right. Now we are able to treat the subject by really taking into account the proper way, in which the insulating cover varies with the copper used in winding. The result is surprisingly simple, and it will therefore be interesting to the members.

The first well-known equation is that if you take a certain deflection of a definite instrument, made of a particular shape and form, and having a certain controlling force, due to a spring or otherwise, is

$$A = \frac{F}{n},$$

where A is the current in amperes, n the number of windings, and F a constant depending on the type of the instrument, but not on A, or on n. Next,

$$n = \frac{P}{D^2},$$

where P is half the area in square centimetres of the cross-section of the coil through its axis, and

$$r = \frac{4\,l\,\rho}{\pi\,d^2},$$

where r is the resistance of the instrument at the temperature it happens to be at, ρ the resistance per cubic centimetre of the metal employed at the same temperature, l the length in centimetres of the wire used in winding the instrument, and d the diameter in centimetres of the *uncovered* wire. Also

$$l = \frac{U}{D^2}$$

where U is the constant volume in cubic centimetres filled with wire, and D the diameter in centimetres of the *covered* wire.

$$\therefore A = \frac{F\,D^2}{P},$$

$$r = \frac{4\,U\,\rho}{\pi\,D^2\,d^2},$$

and the watts required to be expended to produce this deflection

$$A^2\,r = \frac{4}{\pi}\cdot\frac{F^2}{P^2}\,U\,\frac{D^2}{d^2}\rho$$

$$= K\,\frac{D^2}{d^2}\rho \text{ say}$$

when K is a constant depending solely on the type of instrument, but not at all on the gauge or material of the wire. Hence the watts required to produce a particular deflection will be proportional to the ratio of the square of the diameter of the covered wire to the square of the diameter of the uncovered wire multiplied by the specific resistance of the material used in winding the instrument. If $D \div d$ were a constant—*i.e.*, if the diameter of the covered wire increased in proportion to the diameter of the uncovered wire—it would mean, as is well known, that the number of watts required to produce the maximum deflection would be independent of the particular wire used in winding the instrument; the instruments would be equally hot if a particular deflection were obtained, no matter what gauge of wire was employed. But $D \div d$ is not a constant, and is larger for wire of small gauge than it is for wire of a large gauge, and, therefore, an instrument intended to measure many volts will get hotter, when a given deflection is produced, than a similar instrument wound with thinner wire intended to measure fewer volts.

Next we have the equation $V = A\,r$, where V is the P.D. in volts maintained at the terminals of the instrument, when the given deflection is produced.

$$\therefore V = \frac{4}{\pi}\cdot\frac{F\,U}{P}\,\frac{\rho}{d^2}$$

Or the number of volts necessary to produce a particular deflection is proportional to $\rho \div d$, which means simply the resistance of the wire per unit length, the resistance of a centimetre of the wire uncovered. You come, then, to this very simple result. Take any one instrument of a particular type, then the volts required to produce a given deflection simply depends on the resistance of a centimetre of wire whatever the material it is made of, and whatever thickness of silk is used in covering it, and therefore the wire necessary to be used to give the voltmeter a particular range can be easily predetermined. The wire can be wound to any thickness in one instrument, and to any thickness in another, and you can at once say that the volts required to produce a certain deflection in the one is to the volts required to produce the same deflection in the other, simply as the resistance of the uncovered wire per unit length. This idea, which first was suggested to us in a conversation with Mr. Crawley, we have, by the preceding reasoning proved to be generally true, and it enables us to make calculations in a very easy way. It is somewhat surprising, on considering it fully, that when there are three variables—the diameter of the wire, the material of the wire, and the thickness of the insulating cover—employed, that it is so easy to specify what will be the number of volts required to produce a specific deflection—viz., the number proportional to the resistance per centimetre of the wire.

Digitized by Google

Next we want to consider the change of the resistance by heating, which determines the percentage error of a voltmeter—*i.e.*, the percentage variation of the deflection that will be produced by keeping on the volts for a considerable time. The change of the deflection from the moment of first putting on the volts, the diminution in the deflection that occurs after an application of the volts for a considerable time, can be thus determined.

Let ρ_0 be the resistance per cubic centimetre at 0° deg. C. of the material used in winding a voltmeter, T the temperature in degrees centigrade at which the graduations are correct (which we will assume to be the present temperature of the room), and t, the temperature acquired by the instrument when the P.D. necessary to maintain a given deflection is maintained for some time between its terminals, then the rate of production of heat in watts equals

$$K \frac{D^2}{d^2} \rho_0 (1 + a t)$$

where a is the coefficient of increase of resistance per 1 deg. C. of the material used in winding the wire. Let S be the cooling surface of the instrument in square centimetres. ϵ is the rate of loss of heat in watts per square centimetre, per second, which we find equals about 0·001—that is to say, if you have any conductor radiating freely into the air, the temperature, no matter what the conductor is made of, will be raised about one degree above the temperature of the air when one watt per thousand square centimetres of surface is applied to it—that is the value of ϵ.

Hence—

$$K \frac{D^2}{d^2} \rho_0 (1 + a t) = S \epsilon (t - T)$$

$$\therefore t = \frac{S \epsilon T + K \frac{D^2}{d^2} \rho_0}{S \epsilon - K \frac{D^2}{d^2} \rho_0 a}$$

If r_T and r_t be respectively the resistances of the instruments at the temperature of graduation, and when the given deflection has been maintained for some time, the percentage heating error is

$$100 \frac{r_t - r_T}{r_T},$$

which equals

$$100 \frac{\rho_0 (1 + a t) - \rho_0 (1 + a T)}{\rho_0 (1 + a T)}, \text{ or } 100 \frac{a (t - T)}{1 + a T},$$

and this, when the value of t given above is substituted, finally reduces to

$$\frac{100}{\frac{S\epsilon}{a \rho_0 K} \frac{d^2}{D^2} - 1}.$$

Now, how does the diameter of covered wire vary with the diameter of the covered wire? We find from the examination of a large number of samples of wire that the diameter of the covering does not increase by any means in proportion to the diameter of the uncovered wire, but wire varying from ·003in. upwards to ·05in. has an increased diameter of about ·003in. We will take the case of four voltmeters, made identically the same mechanically, one wound with copper, one with german silver, one with platinoid, and one with phosphor-bronze; those seem to be the substances that are most worthy of consideration. We will suppose that the four instruments are so constructed that the same number of volts applied to each instrument produce exactly the same deflection, so that they would be equally good, so far as sensibility is concerned, for the user: if they were all put in parallel they would all give exactly the same deflection to start with. From the simple rule that I gave you it is easy to calculate what must be the diameters of the four metals employed to wind those instruments. We will take one to start with. It will depend upon the given range; suppose the range is such that a 5-mill. copper wire will give the maximum deflection for the number of volts required, it is easy to calculate what must be the diameters of the other wires, because, as I told you, we have a very simple rule connecting the volts required to produce a given deflection with the diameter of the uncovered wire. In fact, we merely have, to settle this question, to simply calculate what must be the diameter of the four wires — copper, german silver, platinoid, and phosphor-bronze—so that they may have the same resistance per centimetre without any regard to whether or not there is the same insulating cover. If you have ·005in. for copper, in order to have the same resistance per centimetre of length, you will have ·018in. for german silver, ·023in. for platinoid, and ·012in. for phosphor-bronze; those are the wires that we must select. If they are all uncovered under ·050in., a manufacturer will cover them all with the same thickness, and the ratio for d to D for copper will be about 5 to 8, for german silver 18 to 21, for platinoid 23 to 26, and for phosphor-bronze 12 to 15; that is, the ratio of d to D, using d so as to have the instruments of the same range, producing the same deflection with the same number of volts. If these values are used, and you take into account the value of a, the temperature coefficient of the different materials, and of ρ_0, you can ascertain the heating error in each instrument. Curiously enough, if you take 5-mill. wire as being the wire right to use in the case of the copper wire voltmeter, to get the right range for the particular instrument, then we find, on substituting the values of $d \div D$ of a and of ρ_0 in the formula given for the heating error, that the metals arrange themselves in the following order as to their relative advantages in using them. It is best to use platinoid, which gives you the minimum temperature error; phosphor-bronze is the next, although phosphor-bronze is a metal not differing in specific resistance so very much from copper—it is a good deal higher, but it is more of the copper order—german silver comes next; lastly, copper. If the instrument be of such a range that ·005 copper is the proper wire to use, then the metals arranged in descending order are platinoid, phosphor-bronze, german silver, and copper; but german silver and copper are nearly equal, so that, curiously enough, our original conclusion of 1885, at any rate for this gauge, was not far wrong in spite of the fact that we assumed that the thickness of the insulation was proportional to the metal, which was wrong. Suppose, next, we are dealing with voltmeters of a lower range. I want, say, four voltmeters to measure, not 100 volts, but all to measure up to only, say, 50 volts. Ten mills. is the proper diameter, we will suppose, for a copper wire for that instrument, then, curiously, the metals arrange themselves in this order of descending value as regards the heating error. Platinoid again comes first—it is the best metal to use—phosphor-bronze again second, but now copper is better than german silver, which is the worst. It appears, therefore, that the idea existing among manufacturers that you ought to make a voltmeter of german silver in order to obtain the minimum temperature error when keeping on the P.D. is quite wrong, as we have always held. It appears to be wrong even when you take into account the real thickness of the insulated covering, and not simply employ an assumed law for the insulating covering.

The conclusion one comes to, therefore, is that you should certainly use platinoid wire, next to that phosphor-bronze, and if you are using a copper wire as thick as 10 mills. it is better to use copper than the equivalent german silver wire; they are very nearly on a par, but it is curious to see that german silver is the worst to employ of the four. This result, bear in mind, is not dependent on the shape or form of the voltmeter.

You will understand that in this consideration I am dealing with the error due to the heating in consequence of keeping on the volts. I am not considering the change of temperature of the room—that is easy enough to allow for—but we are considering the slight falling of the reading which occurs with most voltmeters, due to a prolonged maintenance of the P.D. between the terminals. If the instrument gets hot through the passage of the current, the resistance increases, and its deflection therefore falls. It would be worse to use german silver, if you started with a 10-mill. covered copper wire, than if a copper wire were used; and it would be much better to use platinoid or phosphor-bronze. That is the first conclusion arrived at in this paper.

(To be continued.)

THE ZIPERNOWSKI-DERI ALTERNATE CURRENT SYSTEM.

BY F. B. BADT.

I read with interest the statement in the *Western Electrician* of January 12th that the Zipernowski-Deri transformer system was to be commercially introduced into the United States. It struck me at the time that I had never seen a full and complete description of this interesting system in any of the American electrical journals, and as I have lately returned from Europe, where I had an excellent opportunity of thoroughly looking into the merits of this apparatus, I have undertaken the preparation of this article. The alternate dynamos for lighting by means of transformers made in the United States are all representatives of one type. They all have drum armatures revolving inside of the field, consisting of an iron drum carrying a number of magnets with their poles directed toward the armature. The main type of European alternate dynamos for transformer distribution is that of Ganz and Co. of Buda-Pest, Hungary, which is manufactured under the Zipernowski-Deri-Blathy patents. This system is in operation in a considerable number of central stations on a paying basis. The Zipernowski alternate dynamo belongs to that type which has a stationary drum armature, the field, with its radial magnets, revolving inside. The smaller dynamos are self-exciting, while the larger machines have separate exciters. That the E.M.F. may be kept constant in the primary coils of the transformers —which, of course, are connected in multiple arc—the dynamos are compounded.

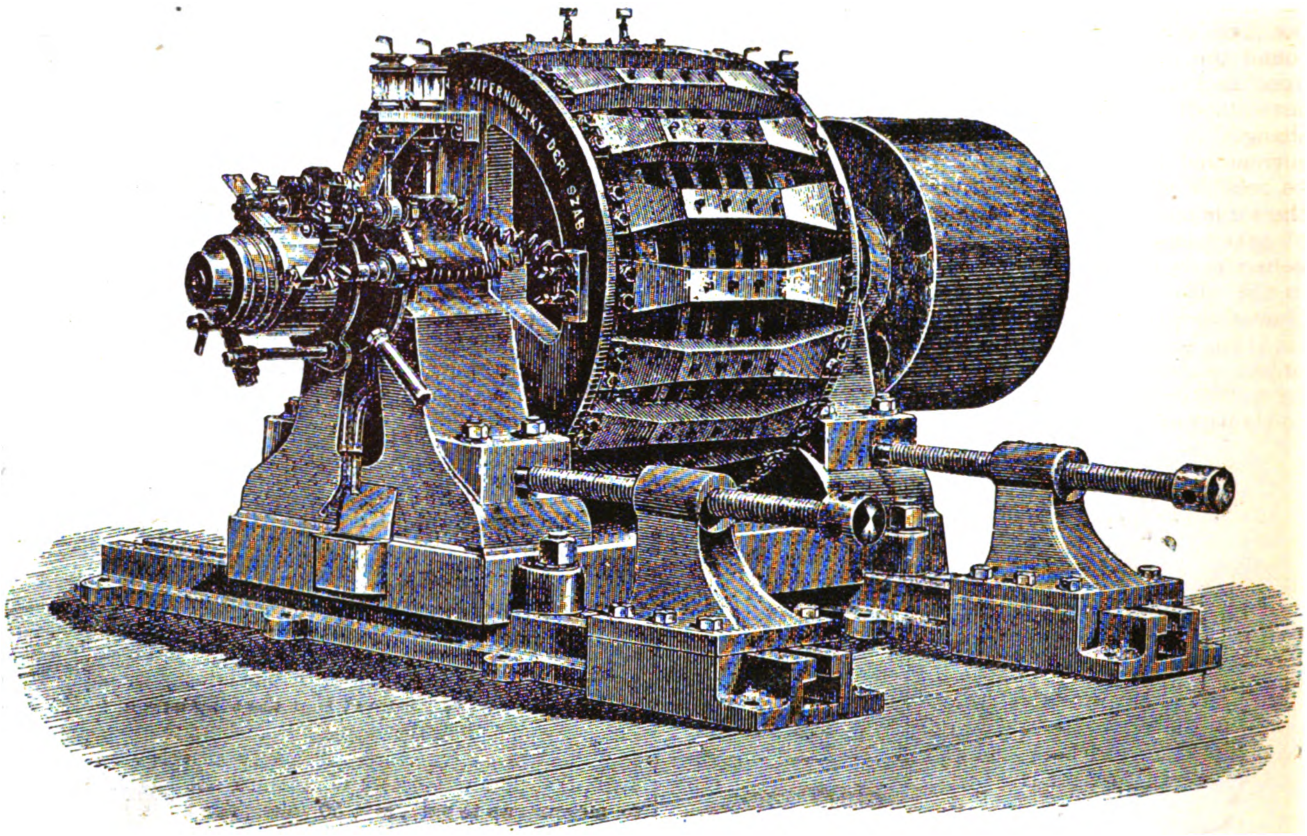

FIG. 1.—Zipernowski-Deri Alternating Current System Self-Exciting Compound Dynamo.

Fig. 1 illustrates a self-existing compound alternate current dynamo. It has eighteen poles, and yields 60,000 watts. The field revolves 500 times per minute. The E.M.F. is 1,800 volts and the commercial efficiency of the dynamo is 90 per cent.

The armature is composed of a stationary laminated iron drum of cylindrical form, on the inner side of which are disposed the armature-coils of curved form (Fig. 2) wound on iron cores, not shown in the cut. The radial field-magnets, with their respective coils, constitute the moving part. The commutator has as many segments as there are magnet poles in the machine, the alternating segments being in electrical contact with each other, as shown in Fig. 3. At each reversal the commutator so directs the alternating currents that the several impulses follow in the same path in the coils of the magnets, and thus the machine becomes self-exciting. The current necessary to excite may be taken as a shunt to the terminals of the generator or from a special armature-coil reserved for this purpose. The exciting current may also be furnished by a transformer called a magnetiser, connected to the main line or the terminals of the generator. In all these cases the exciting current, supposing the dynamo to be already compounded, would be of nearly constant E.M.F. and

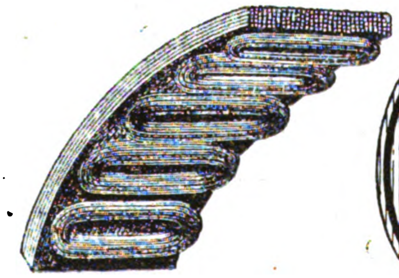

FIG. 2.—Section of Armature.

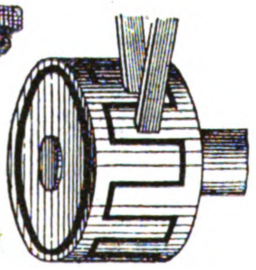

FIG. 3.—Commutator for Self-Exciting Alternating Dynamo.

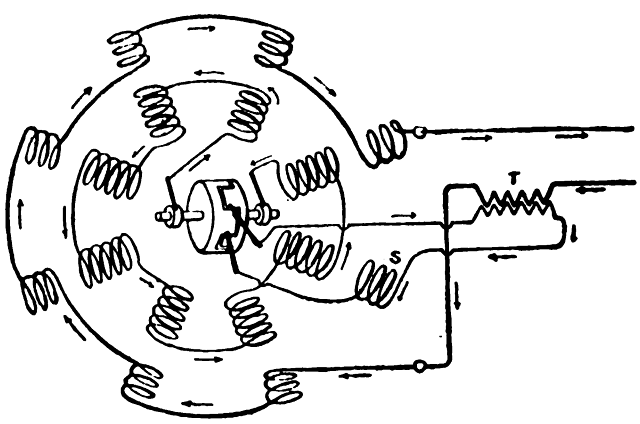

FIG. 4.—Plan of Compound Alternating Dynamo

Digitized by Google

strength. But for maintaining a constant E.M.F. at the terminals of the generator it is necessary to increase the magnetisation in proportion to the increase of the external current supplied by the generator, and as it is even desirable to have a somewhat higher E.M.F when the generator is running with full load as when an open circuit, the magnetisation will have to be increased very considerably. In this case the magnetising current traverses one of the coils of a special transformer, or compensator, while the second coil of this compensator is introduced in the main circuit of the generator in such a manner, that the two currents are circulating in opposite directions round the iron core. The two currents will mutually act upon each other, and the effect will be that the exciting current will increase and decrease, corresponding to the changes in the main current. If the original exciting current and the compensator are properly adjusted, it will be possible to maintain the E.M.F. constant, not only at the terminals of the dynamo, but at the end of a conductor of given length. The E.M.F. at the terminals of the generator will rise somewhat with the increasing intensity of the main current. By such an arrangement the influence of part of the resistance of the high tension main line can be done away with in cases where the nearest object to be supplied is situated at a considerable distance from the central station. Fig. 4 is a diagram of an eight coil compound alternate dynamo. The inside coils are

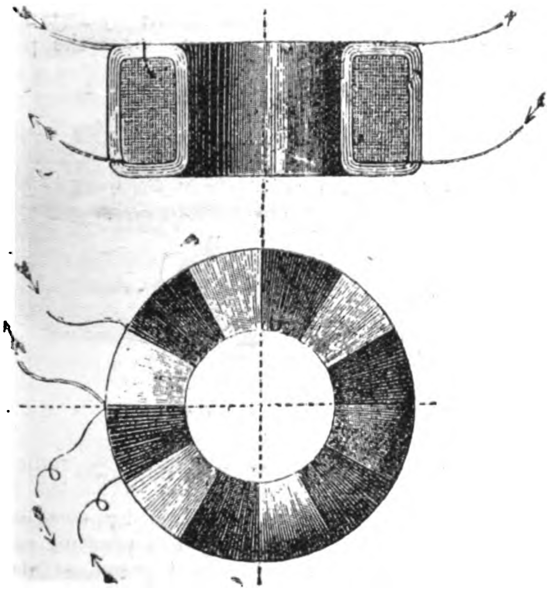

Fig. 5.—Transformer, Form No. 1.

those of the field, and the outside coils those of the stationary armature. The current of the armature-coil, S, is reserved for the magnetisation of the field, and for this purpose is connected with the commutator. T is the compensator. It is clear that instead of using the current of coil S, a transformer might yield the magnetising current for the field.

Ganz and Co. build their alternate dynamos in the following sizes:

Type.	1	2	3	5	6	7	8
Watts:	10,000	20,000	30,000	50,000	80,000	160,000	320,000
Revol. per min.:...	830	830	625	500	360	170	125
No. of magnets....	6	6	8	10	14	30	40
E.M.F...............	900	900	1,800	1,800	3,600	3,600	3,600
Per cent. commercial efficiency....	85	85	90	90	92	92	93

The Zipernowski transformers have been described too often and are too well known to require any minute description. Two forms are generally used. In the first form (Fig. 5) a ring or hoop-shaped iron core, made of thin iron wires, ribbons or plates, is wound with two coils of copper wire much in the manner of a Gramme ring. The windings, however, are connected in such a way, that the primary current circulates in all spires in the same direction round the core, and no free magnetic poles are formed. In the second form (Fig. 6) the iron and copper parts are reversed, the two coils of copper wire forming a ring or hoop which is completely enclosed by thin iron wires, ribbons or sheet iron, the subdivided iron conveying the lines of magnetic force. The more delicate copper windings are entirely enclosed by the iron, and thus shielded against accidental damaging.

A transformer of the latest design, having 10 h.p. nominal capacity, gives the following electric data:

Weight of iron core		90 kilogrammes
,, copper in primary coil		16 ,,
,, ,, secondary coil		22 ,,
Resistance of primary coil		4·6 ohms.
,, secondary coil		0·013 ,,
Difference of potential at primary terminals		1,873 volts.
Difference of potential at secondary terminals		102 ,,
Ratio..		18 to 1
Strength of primary current......	with full load on	4·28 amperes.
,, secondary ,, ...	with full load on	75 ,,
Primary energy consumed	with full load on	8,017 watts
Secondary energy supplied	with full load on	7,650 ,,
Commercial efficiency...............	with full load on	95·4 per cent.
Reversals of current..		100 per second.

On open secondary current this transformer will take 17 amperes of primary current, which is equal to 210 watts of energy expended, though the apparent product of volts and amperes will give about 50 per cent more.

Prof. Galileo Ferraris, who made a series of experiments and measurements at the Italian Museum of Industry in Turin, concludes his report, in which he compares transformers of the Gaulard and Gibbs and Zipernowski and Deri types as follows:

"The comparisons which we have just made are sufficient to demonstrate that the annular form of transformer is

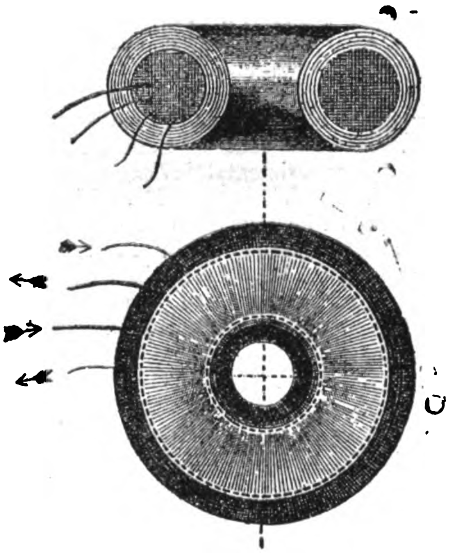

Fig. 6.—Transformer, Form No. 2.

much better than that of the disc secondary generators. This is easily explained, for we can demonstrate *a priori* that the form of the annular transformer is not merely very rational, but that it is, perhaps, the best of all that could be devised for the purpose of obtaining great coefficients of induction with low resistances and small weights of copper.

"1. To have a large surface of spirals with the smallest possible mass of metal, we must remove as much as possible of the metal from the centre of the spirals, and consequently we prefer wire to discs.

"2. To obtain the largest surface of spirals possible with the least length of wire, we must have a small number of spirals with a great diameter.

"3. To give the iron core the maximum efficiency, it is advantageous to give it a closed form. Now the layer of iron which covers the annular transformer is evidently equivalent to a core closed upon itself.

"4. To avoid Foucault currents, the continuity of the iron must be interrupted precisely as it is done by employing, instead of a single mass, a varnished iron wire, rolled up in such a manner as to be everywhere perpendicular to the currents.

"We are thus led, quite naturally, to the arrangement adopted by Zipernowski, Deri, and Blathy.

"Lastly, it must be noted that the induction produced by the currents which circulate in the coils of the annular transformer is sensibly independent of the place which

Digitized by Google

these coils occupy in the interior of the stratum of iron, where they are entirely enclosed, and that consequently, both in the annular transformer and in that with the discs, the primary and secondary coils are under identical conditions as regards the iron."

Ganz and Co. manufacture, in connection with their alternate dynamos and transformers and necessary appliances, also alternate current meters and alternate motors, of which a description will be given at some future time. They do not make incandescent lamps, but use in their stations lamps of various manufacturers, such as Siemens, Edison-Swan, Cruto, and others.—*Western Electrician.*

ON THE DESIGNING OF CONTINUOUS CURRENT DYNAMO MACHINES.*

BY PROF. JAMIESON, M.INST.C.E., F.R.S.E.

No machine has received such constant and unremitting attention of late as the dynamo, both from men of science and from practical engineers. From being a comparatively badly designed and inefficient machine, in 1880 giving then only some 50 to 60 per cent. commercial efficiency, it now produces over 70 per cent. of the dynamic power applied to it in the form of useful electrical power, and the electrical efficiency or ratio of electrical output to total electrical power generated often exceeds 90 per cent. Until within a very few years ago, dynamos were designed and proportioned by a rule of thumb system, or trial and failure until moderate success was attained. If a maker had luckily hit upon successful results from one machine, he copied by proportion the dimensions and materials arrived at for his other larger or smaller machines, without exactly knowing the precise causes which gave success in the one case, or failure in the other. Now all that is changed, thanks to the mathematical and experimental investigations of Dr. John Hopkinson, Prof. S. P. Thompson, Mr. Gisbert Kapp, and many of the more eminent makers of dynamos, as well as to the very exact experiments by Prof. Ewing on the magnetic permeabilities of different classes of iron.

If a dynamo is now required to give any desired power, the whole of its proportions and sizes can be calculated and drawn down with such accuracy that, when constructed, it will fulfil the stipulated conditions to within 2 or 3 per cent., with a minimum of experiment and alteration in the workshop.

Let me here add the power is not measured by any system of "nominal power," but by actual, useful output. Engineers have of late been discussing in this institution whether or not they should adopt one or other of the various rules for estimating the "nominal horse power" of steam-engines. Nothing gives greater annoyance to an electrical engineer than having to reply to the question, "What is the nominal horse-power required to drive such and such a dynamo?" He at once discards this term, and deals directly with the brake, or indirectly with the i.h.p. of the engine.

In the short time at the disposal of the author, he proposes to confine his remarks and calculations to "Continuous Current Constant Pressure Compound Dynamos," as now used for supplying current to ordinary incandescent lamps arranged upon the parallel system, or those dynamos which work in accordance with the methods illustrated by Figs. 1 and 2.

C_a, C_m, C_s, C_e, represent the currents in the armature, main magnet-coils, shunt-coils, and external circuits respectively, the direction of these currents being indicated by arrows.

R_a, R_m, R_s, R_e, represent the resistances of these same parts.

E_a and E_e represent the E.M.F. or pressure generated in the armature, and the external E.M.F., or difference of pressure between the positive and negative terminals (T + and T –) respectively.

A M and V M represent current and pressure meters, or ampere and volt meters.

It is not our intention to enter here into the many mechanical and electrical arrangements of dynamos, or to trace the manner in which dynamos have been gradually simplified and cheapened. Yet as many of the members of this institution are not familiar with the internal construction of such machines, we think that the simple illustrations may assist them, and lead them to take a greater interest in the principles and formulæ which follow.

The first skeleton figure gives an idea of the general arrangement of the series Gramme dynamo, one of the few, and certainly the best machine in the market in 1880.

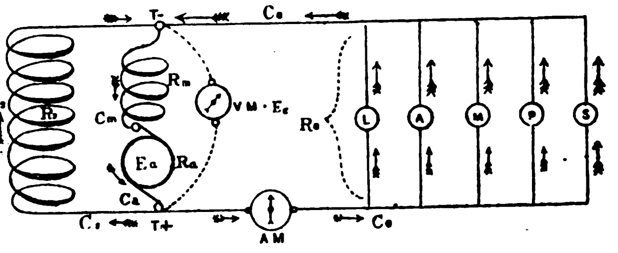

FIG. 1.—Theoretical diagram of Faraday dynamo connections. Ca, Cm, Cs, Ce represent the currents in armature, main magnet coils, shunt coils, and external circuits respectively, the direction of these currents being indicated by arrows; Ra, Rm, Rs, Re represent the resistances of these parts; Ea, Ee represents the E.M.F. in armature and on external circuit.

Fig. 1 illustrates the Faraday dynamo, as made in 1887-88. This form of dynamo gives excellent results, but the makers finding that it is more expensive to construct than the Kennedy dynamo shown by Fig. 2, they are now getting out a set of patterns to meet the present popular craving for cheap machines, with cast-iron core and pole-pieces having but one joint, instead of a wrought-iron core and two joints.

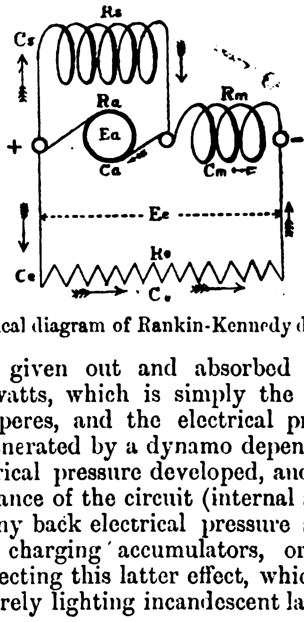

FIG. 2.—Theoretical diagram of Rankin-Kennedy dynamo connections.

The power given out and absorbed by dynamos is measured in watts, which is simply the product of the current in amperes, and the electrical pressure in volts. The current generated by a dynamo depends directly upon the total electrical pressure developed, and inversely upon the total resistance of the circuit (internal and external), as well as upon any back electrical pressure such as is experienced when charging accumulators, or when driving motors. Neglecting this latter effect, which does not take place when merely lighting incandescent lamps,

Let E_a represent the electrical pressure generated in the armature.

E_e „ external electrical pressure, or that available for useful work.

R_i „ internal resistance of the whole dynamo.

R_e „ external resistance of leads and lamp circuits.

C_a „ current passing through armature.

C_e „ current external, or that sent through lamp circuit.

Then, $C_a = \frac{E_a}{R_i + R_e}$ = total current generated

And, $C_e = \frac{E_e}{R_e}$ external current.

The electrical efficiency $= \frac{C_e \times E_e}{C_a \times E_a} = \frac{\text{output in watts}}{\text{total watts generated}}$.

Now, since C_a, E_e, and C_e depend directly upon E_a, we propose to show how this internal electrical pressure may be obtained for any dynamo of the kind under consideration.

* Paper read before the Institution of Engineers and Shipbuilders of Scotland.

Digitized by Google

This total or internal pressure, E_a, depends directly upon:

1. The total number of magnetic lines which flow between the field-magnet poles through the armature.
2. The number of convolutions of the armature conductors which are in series at one time.
3. The speed of rotation of the armature.

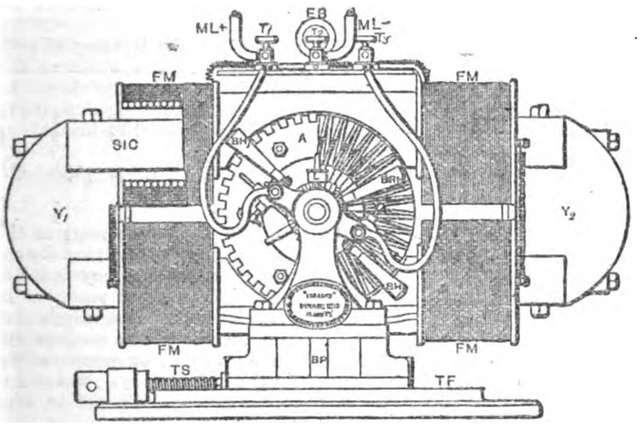

FIG. 3.—Faraday dynamo. BP, bed plates; TF, tightening frame; TS, tightening screw; FM, field magnets; Y_1Y_2, field magnet yokes (cast-iron); SIC, soft iron cores; A, armature; BH_1BH_2, brush handles; ML+ ML−, main leads (positive and negative); $T_1T_2T_3$, terminals.

The *number of revolutions* per minute is a matter that can be easily decided upon before beginning to design the dynamo. Fast-speed dynamos, if well balanced, are common in land installations; slow-speed ones on board ship, and when vibration and noise must be avoided.

The *number of convolutions* of the armature conductor depends upon the number of radial bars in the commutator, the diameter of the armature, and the size of wire to be used, all of which will be determined as the drawing or design proceeds in accordance with sound practice.

The *magnetic circuit* is the chief and most intricate part of the whole design which requires our attention, and we shall therefore consider it first in full detail.

I. Field-Magnet Circuit.

The field-magnet circuit should have as little magnetic resistance as possible. The magnet cores, etc., *should* therefore be made of the best soft Swedish iron, short, of large sectional area, and with no joints. Owing, however, to expense, the difficulty of winding the wire on the magnets, or the fixing of bobbins containing the wire, and the necessity of having sufficient residual magnetism with which to start the dynamo current, and to prevent fluctuations of current, the yoke (if there is one) and the pole-pieces are frequently made of cast iron.

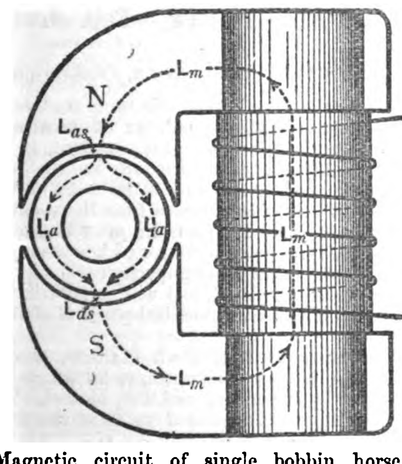

FIG. 4.—Magnetic circuit of single bobbin horse shoe Kennedy dynamo. Lm represents length of field magnet circuit; Las represents length of air space circuit; La represents length of armature circuit.

In a Kennedy dynamo (Fig. 4), the mean length of the magnetic circuit is indicated by the letter, $\mathbf{L}_m$, and the poles are marked N and S.

II. Air Spaces.

The air spaces should have the least possible magnetic resistance. They should, therefore, have as little depth as is consistent with preventing actual contact between the armature wires and the pole-pieces, and of allowing free circulation of air, and of preventing heating of the pole-pieces due to Foucault or eddy currents in the forward ends of the pole-pieces.

In Fig. 4 the two air-spaces are marked, $\mathbf{L}_{as}$, $\mathbf{L}_{as}$.

III. Armature Core.

The armature core should have as little magnetic resistance as possible, and be as free as possible from inducing Foucault currents. It should, therefore, be built up of the softest thin Swedish iron plates, well insulated from each other, and laminated or placed in a direction parallel to the direction of the magnetic lines passing between the poles of the field-magnet. Some makers prefer to build up their armature cores of soft-iron wire insulated by the natural thin coating of oxide of iron always found on such wire.

In Fig. 4, the mean directions of the split magnetic circuit through the armature core are marked $\mathbf{L}_a$, and $\mathbf{L}_a$.

IV. Magnetic Resistance of Field-Magnet Circuit.

The magnet circuit, $\mathbf{L}_m$, has a magnetic resistance.

$$\mathbf{R}_m = 2\frac{\mathbf{L}_m}{\mathbf{S}_m}.$$

Where—

2 = Kapp's coefficient for the initial specific magnetic resistance of soft wrought iron (the number 3 to be used if core, etc., be of cast iron).

$\mathbf{L}_m$ = the mean length of field-magnet circuit in inches.

$\mathbf{S}_m$ = sectional area in square inches (at right angles to $\mathbf{L}_m$) of magnet core.

V. Magnetic Resistance of Air Spaces.

The air spaces circuits, $\mathbf{L}_{as}$, $\mathbf{L}_{as}$, have a resistance,

$$\mathbf{R}_{as} = 1440\frac{2\,\mathbf{L}_{as}}{\mathbf{S}_{as}}.$$

Where—

1440 = Kapp's coefficient for the specific magnetic resistance of air and copper when wrought-iron magnets are used (1800 to be used with cast-iron magnet cores and pole-pieces, and 1500 with wrought-iron cores and cast-iron poles).

$\mathbf{L}_{as}$ = depth of each air space in inches (and since there are two spaces, $2\,\mathbf{L}_{as}$ is inserted in the formula).

$\mathbf{S}_{as}$ = sectional area of each air space or surface area of each pole-piece in square inches.

VI. Magnetic Resistance of Armature Core.

The armature core circuits, $\mathbf{L}_a$, $\mathbf{L}_a$, have a magnetic resistance.

$$\mathbf{R}_a = \frac{\mathbf{L}_a}{\mathbf{S}_a}$$

Where—

$\mathbf{L}_a$ = mean average length of armature core magnetic circuit in inches (if there was only but one path instead of two we should have to multiply by the coefficient 2, as in equation IV., but $2\,\frac{\mathbf{L}_a}{2} = \mathbf{L}_a$).

$\mathbf{S}_a$ = cross sectional area of armature core in square inches.
= twice radial depth × length of armature core.

VII. Total Magnetic Resistance.

The total magnetic resistance of the complete magnetic circuit is therefore—

$$\mathbf{R}_m + \mathbf{R}_{as} + \mathbf{R}_a = 2\,\frac{\mathbf{L}_m}{\mathbf{S}_m} + 1440\,\frac{2\,\mathbf{L}_{as}}{\mathbf{S}_{as}} + \frac{\mathbf{L}_a}{\mathbf{S}_a}.$$

VIII. Kapp Lines.*

The total number of Kapp lines, $\mathbf{K}_L$, of magnetic force which pass through the magnet and air space can there-

* A Kapp line is simply = 6,000 C.G.S. magnetic lines. Kapp proposed this unit (see *Journal* Society Telegraph Engineers and Electricians, vol. xv., p. 518, 1886) as a suitable factory unit for dynamo use, on account of the C.G.S. unit being so small; also from the fact that the revolutions of dynamo-armatures are usually reckoned per

Digitized by Google

fore be calculated by *dividing* the ampere-turns ($A \times T_{mw}$) on the magnet windings by the total magnetic resistance in the magnetic circuit.

Or,
$$\mathbf{K}_{L,} = \frac{A \times T_{mw}}{\mathbf{R}_m + \mathbf{R}_{as} + \mathbf{R}_a}.$$

i.e.,
$$\mathbf{K}_{L,} = \frac{A \times T_{mw}}{2\frac{\mathbf{L}_m}{\mathbf{S}_m} + 1{,}440\frac{2\,\mathbf{L}_{as}}{\mathbf{S}_{as}} \times \frac{\mathbf{L}_a}{\mathbf{S}_a}}.$$

IX. E.M.F. in Armature.

The E.M.F. developed internally in the armature winding is— $E_a = \mathbf{K}_{L\,a} \times T_{aw} \times N_{ar} \times 10^{-6}$.

Where—

E_a = E.M.F. developed in armature in volts.

$\mathbf{K}_{L_a}$ = Kapp lines which only pass through armature or the useful field.

T_{aw} = turns of armature wires in series (counted all round core).

N_{ar} = number of armature revolutions *per minute*.

Example I.*—Let us now apply the foregoing formulæ to the design of a single field compound dynamo of similar form to that shown in Fig. 2.

Let the dynamo be furnished with a long shunt, and be of 6,400 watts (external power, P_W), when driven at 1,000 revolutions per minute.

First, let us determine the resistance, current, fall of potential in armature and magnets, and percentage loss of power in the armature, shunt, and main field-magnet coils, using the same symbols as before.

Given $E_e = 100$ volts.

$C_e = 64$ amperes.

Resistances.—Then $R_e = \frac{E_e}{C_e} = \frac{100\,v}{64\,a} = 1{\cdot}55$ ohms.

(*To be continued.*)

REPORT ON THE LIGHTING AT BARNET.

At last week's meeting of the Barnet Local Board a report by Mr. W. H. Preece on the subject of the electric lighting of the town, together with one by his assistant (Mr. Probert) on his photometrical testing of the lamps, was considered. Mr. Preece's report was as follows:

W. H. Mansbridge, Esq. London, Feb. 11, 1889.

Dear Sir,—In accordance with the request contained in your letter of the 23rd of January, and with the resolution of the Board passed on the 15th of January, I have pleasure in informing you that I visited Barnet on the 28th ult., in company with Mr. Joel, and inspected the whole of his arrangements there. My assistant, Mr. Probert, an expert in light measurements, visited the locality on the 2nd and 4th inst. ; and I attach his report to me on the result of his photometric measurements. I answer now the several questions you have asked me.

1. *Q.* Are all the 71 lights of 32 c.p. each? If not, of what power are they?—*A.* It will be seen from Mr. Probert's report that the lamps are not all of the candle-power specified.

2. *Q.* Is the machinery now employed capable of supplying the 71 lamps with 32-c.p. light?—*A.* The machinery now employed is capable of supplying 71 lamps with 32-c.p. light.

3. *Q.* Can you give us any data whereby in the future we may determine for ourselves whether we are getting the amount of light stipulated for in the contract?—*A.* It would be difficult to measure the light except by photometric means, which require the services of an expert, but which are not difficult to master.

4. *Q.* Are all the lamps of uniform power?—*A.* The lamps are not by any means of uniform power.

5. *Q.* Would the present machinery be capable of working another 12 or 15 lights?—*A.* The present machinery might be capable of working another 12 or 15 lights; but it would be most impolitic to add more lights without additional apparatus to provide against the possibility of a breakdown.

I consider that it is a great risk to continue the lighting of your roads and streets with the existing apparatus. The whole of the apparatus in the central station worked by the contractor should be duplicated. I am sorry to see that such an interesting experiment as the illumination of your parish has been jeopardised by insufficient means to maintain the light uniform and steady.

(Signed) W. H. Preece.

[Enclosure.]

In submitting the results of my photometric measurements of the electric lamps in the streets of High Barnet, I beg to add that during the two evenings of Feb. 2 and 4 the lights were, in my opinion, all that could be desired. There is, however, a marked variation in the strength of light given out by the lamps tested. This may be due to absorption of light by the thick glass globe which encloses the electric lamp; to atmospheric absorption; to dirt or grease on the globe obscuring a large proportion of the luminous rays; and to the lamp filaments having deteriorated through use. For absorption, etc., I think the measurements might justly be increased 20 per cent. at least to represent the actual candle-power of the lamps; and I have therefore in the annexed table furnished a column which shows the results of 20 per cent. augmentation. With this addition, the average candle-power of the lamps, numbered 1, 10, 22, 33, 37, 42, 44, 48, 53, and 58 is 27¼. The mean candle-power for the electric lamps, as measured photometrically, is 22·71. The gas lamp was found to equal 12·48 standard candles; hence the average illuminating power of the former shows a percentage increase of 40·6 as compared with the latter.

Appended to the report was a table giving the following figures:

Lamps Tested.	Candle-Power.		Candle-power with 20 p. ct. for absorption.
Hadley-green	21·423*	...	25·70
High-street (10th lamp from Hadley-green	36·378	...	43·65
Do. (first lamp from station)	100·000	...	120·00
Do. (junction with Wood-street	105·670†	...	126·82
Park-road	14·450	...	17·34
Manor-road	15·340	...	18·34
Black Horse	25·837	...	31·00
Bells-hill	22·700	...	27·24
Wood-street (top)	14·650	...	17·58
Union-street (second lamp from High-street	22·457	...	27·00
The Avenue (third lamp from Black Horse)	34·269	...	41·123
Salisbury-road	19·563	...	23·475
Gas lamp at top of Barnet Hill, which should be 16 c.p.	12·480	...	14·98

* The contract power of the lamps is 32 candles.

† This was a "Sunbeam" lamp put up for exhibition. It has since been removed, and replaced by an ordinary lamp.

A discussion followed the reading of the reports, the result of which ended in a resolution being carried, "that the contractor be called upon to provide uniform lights of 32 c.p. within 14 days."

PHYSICAL SOCIETY.—Feb. 9.

Annual General Meeting.—Prof. Reinold, President, in the chair.

The reports of the council and treasurer were read and adopted. From the former it appears that the number of members has only slightly increased during the year, due, it is supposed, to the advantages offered by the society not being generally known, and a flyleaf has been prepared giving a short account of the society's objects and procedure, copies of which may be obtained from the secretaries.

During the past year Vol. I., Part I., of "Physical Memoirs Selected and Translated from Foreign Sources," has been printed and issued to members, and translations of important memoirs by Fourier, Hittorf, and Volta are well advanced, and will be published shortly.

The treasurer's report showed the financial position of the society to be very satisfactory.

Owing to the lamented death of Prof. Clausius, a vacancy has occurred in the list of honorary members, to fill which Prof. R. W. Bunsen was nominated by the council and duly elected.

The following gentlemen were elected to form the new council: President, Prof. A. W. Reinold, M.A., F.R.S.; vice-presidents, Dr. E. Atkinson, Prof. W. E. Ayrton, F.R.S., Shelford Bidwell, M.A., LL.D., F.R.S., the Right Hon. Lord Rayleigh, M.A., D.C.L., Sec. R.S.; secretaries, Walter Bailey, M.A., Prof. J. Perry, F.R.S.; Treasurer, Prof. A. W. Rücker, M.A., F.R.S.; demonstrator, C. Vernon Boys, F.R.S.; other members of council, Hon. R. Abercromby, T. H. Blakesley, M.A., M.I.C.E., W. H. Coffin, Conrad W. Cooke, Prof. O. Lodge, D.Sc., F.R.S., Prof. W. Ramsay, Ph.D., F.R.S., W. N. Shaw, M.A., Prof. S. P. Thompson, D.Sc., H. Tomlinson, B.A., C. M. Whipple, D.Sc. Cordial votes of thanks were passed, 1st, to

minute instead of per second, and that British workmen still measure sectional areas in square inches instead of square centimetres as in the C.G.S. system.

The number 6,000 is made up of two terms—viz., 60, which enables revolutions to be counted per minute instead of per second; and 100, to bring down the measurement of the magnetic lines to reasonable numbers; or $\frac{\text{C.G.S. lines}}{60 \times 100} = \frac{\text{C.G.S. lines}}{6{,}000}$. Then, 1 Kapp line = 6,000 C.G.S. lines.

Since there are 6·4514 square centimetres in a square inch,

1 Kapp line per square inch $= \frac{6{,}000}{6{\cdot}4514} = 930$ C.G.S. lines per square centimetre. Consequently, instead of saying 18,600 C.G.S. lines, we simply say 20 Kapp lines or $\left(\frac{18{,}600}{930}\right)$, which gives small numbers more easily expressed and understood by those engaged in dynamo construction; in the same way that for long distances we prefer to measure lengths in miles instead of in yards or in inches. I have not explained how Mr. Kapp arrived at the above constants, or how they agree (for all practical purposes) with Hopkinson's formulæ—viz., that the magnetic resistance of each part of the circuit is proportional to its length, and inversely proportional to the product of its sectional area and magnetic permeability (as found by experiment at a particular magnetic density). We shall endeavour to explain these points in the discussion if an opportunity permits.

* The calculations for example I. were made by Boucher's Calculator, and thus are therefore only approximately true.—A. J.

Digitized by Google

the Lords of the Committee of Council on Education for the use of the rooms and apparatus of the Normal School of Science; 2nd, to the council and officers of the society for their services during the past year; and 3rd, to the auditors, Mr. Inwards and Prof. Minchin, for examining the accounts. In returning thanks for the council and officers, the President attributed the great success of their meetings to the indefatigable zeal displayed by the hon. secretaries.

The meeting was then resolved into an ordinary science meeting, at which Mr. James Wimshurst and Mr. Percy W. Sellon were elected members.

Prof. A. S. Herschel, D.C.L., F.R.S., read a paper on "**Physico-Geometrical Models**," and exhibited a collection of geometrical figure models illustrating elementary forms of crystallographical and chemical form constructions. The subject, he said, had suggested itself to him as an important one for study some five years ago, from the possibility which he then discovered of effecting a four-limbed mechanical cycle, similar to a thermodynamic cycle, with a conically-revolving pendulum, the mathematical conditions of whose motion involved the logarithm of the circle radius of the knob's revolution, as a quantity equivalent to entropy in the thermal cycle. The mechanical cycle may be effected as follows: Suppose the pendulum knob to be revolving at velocity V_1, and radius r_1, imagine the controlling force to decrease so that the radius varies from r_1 to r_2, the velocity remaining constant at V_1; then increase the controlling force to its original value and simultaneously impart velocity to the knob to keep the radius constant at r_2, the final velocity being V_2. Next further increase the controlling force so as to cause the radius to decrease to r_2 at velocity V_2, and finally decrease the controlling force to its initial value, simultaneously retarding the knob till the velocity is V_1 at radius r_1. The nett energy concerned in the operations was given as $W = (V_1^2 - V_2^2)$, and where $\phi = \log. \frac{r_1}{r_2}$, and the cycle affords an illustration of transformation of gyratory motion into energy of reverberatory push along the axis. The logarithm, ϕ, is also measured by the area of a hyperbolic sector, and is connected (as was shown) with a sector of the circle which a lamp's conical beam would inscribe upon a square glass screen or plate, dividing a long room of square cross-section into two parts. The conical beam, prolonged through the glass, then traces on the walls beyond hyperbolas, whose sectors, from their summits, are related to the circle's corresponding sectors by a well-known hyperbolocyclic trigonometrical connection. From this mode of constructing the connection, and from a discordance which it shows at the asymptote extremities with Euclid's definition of parallel straight lines, the author concludes that cubic space cannot be continuous in its structure, but must be in a physically constructive sense, like material particles, indestructively atomic or molecular. The models showed modes of constructing cubic space in various ways, chiefly by means of tetrahedra, octahedra, and dodecahedra, the common element of form in these being also shown to be the right-angled tetrahedron, or "biquoin," obtained by dividing a cube into six equal parts by three planes through its diagonals. A model of Sir W. Thomson's soap foam figure, and some wooden models representing Haüy's polyhedral atoms and their combinations, were used to illustrate the structural view thus taken of geometry, and chemical figure models of the ring of tetrahedral carbon molecules in benzene, and of the symmetric groups of similar atoms in active and inactive tartaric acid, were shown.

NEW COMPANIES REGISTERED.

Mines and General Telpher Company, Limited.—This Company has been registered by Messrs. Lee and Pemberton, 44, Lincoln's-inn-fields, W.C., with a capital of £4,000 in shares of £1 each. Object: to construct and work lines for the carriage of minerals and other materials under a license from the United Electrical Engineering Company.

Graphophone Syndicate, Limited.—Registered by Sydney Morse, solicitor, 4, Fenchurch-avenue, E.C., with a capital of £100,000 in shares of £10 each. Object: to acquire the seven British patents taken out by Bell and Painter, with applications for others now pending, and to carry into effect an agreement made between Woodhouse and Rawson, Limited, of the one part, and John Hamilton Ward, as trustee for and on behalf of this Company, of the other part, and Walter T. Glover and Co. of the one part and John Hamilton Ward, as trustee on behalf of this Company, of the other part; to carry on the business of engineers and contractors for the manufacture, supply, sale, exchange, letting on hire of plant, machinery, implements or devices for recording and reproducing sound, recorders, cylinders, etc. The first subscribers are:

	Shares.
F. L. Rawson, 11, Queen Victoria-street, E.C	1
J. H. Ward, 55, Shelgate-road, Wandsworth	1
J. P. St. Quenton, 38, Lee-road, Lee, Kent	1
J. MacFarlan, Invermay, Wimbledon	1
Sir R. W. Rawson, K.C.M.G., C.B., 68, Cornwall-gardens, S.W.	1
Sir F. L. McClintock, 8, Atherstone-terrace, S.W.	1
G. Offor, Peak Hill Villa, Sydenham	1

The number of Directors shall not be less than three nor more than nine, of which one-third shall be nominated by the Volta Graphophone Company of Virginia, United States of America. The first Directors of the Company shall be nominated by the signatories to the memorandum of association. The qualification of a Director shall be the holding in his own right of at least £100 shares in the capital of the Company. The remuneration of the Directors shall be determined in general meeting, but so that in no case shall such remuneration exceed £1,000 per annum.

COMPANIES' MEETINGS.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

The twenty-fifth ordinary general meeting of this Company was held on Tuesday at the offices, Old Broad-street.

Mr. Philip Rawson, who presided, observed that the accounts did not enter largely into details, but it would be very unwise for such a Company as theirs to do so. They were still enabled to recommend a dividend of 20 per cent. for the year. During the past year the factories, both at Greenwich and at the gutta-percha works at Wharf-road, had done a considerable amount of work. About 6,000 miles of telegraph wire had been insulated, including submarine and land lines. Their steamers had repaired the Brazilian Submarine cable in January and August, the German Union cable, and the Heligoland cable. The "Scotia" was also employed for three months in repairing the Direct United States cable. A line was also laid of about 456 miles connecting the Dutch Settlements with Java and Macassar, and the steamer afterwards left this country to connect Java with Western Australia by a cable about 1,000 miles long. That cable had been successfully laid, making now the third line to Australia. A further contract had been entered into for connecting the West African system with the Cape, and the length of cable required was 1,350 miles. The greater part of the cable was manufactured this year, and the vessel would sail with it at the end of this week. This cable commenced from a place called Mossamades, a Portuguese settlement on the West Coast of Africa, and it would when completed be laid to Cape Town. Africa would then be surrounded on all sides by cables. The steamship "Kangaroo," which was chartered by the Italian Government for distilling water in the Red Sea, had been returned to the Company, and had since been sold. Their steamship "Calabria" had been chartered from them on very good terms to make a large number of voyages between Antwerp and the River Plate for emigration purposes. The Company's works at Greenwich and Wharf-road were in excellent working order. To fill the vacancy at the Board caused by the death of Lord Alfred Paget, who assisted them for 18 years, they had appointed Mr. William Shuter, who had been connected with the Company from the beginning. The £150,000 of debentures bearing 6 per cent. had been renewed at 5 per cent. Passing to the balance-sheet, he stated that the debts owing to the Company were perfectly good, and the sundry securities, which figured at the close of the year for £468,641, represented securities which, perhaps, were a little more valuable than the amount stated. The net profit on the year's working was £82,580. He concluded by moving the adoption of the report and the payment of a dividend of £1. 16s. per share, making with the interim dividend £2. 8s. a share, or 20 per cent. for the year.

Mr. George W. Campbell seconded the motion, which was unanimously adopted, and the retiring Directors and Auditors were afterwards reappointed.

SUBMARINE TELEGRAPH COMPANY.

The half-yearly ordinary general meeting of this Company was held on Tuesday at the offices, 2, Throgmorton-avenue, London-wall.

The **Hon. H. R. Brand** presided, and in moving the adoption of the report and accounts said that they showed a progressive business, the main consideration which affected the proprietors being that they had to part with it. Another feature, of a more satisfactory character, was that there was a large sum of money invested in various stocks, upon which, if they took their price at the present time, there was a profit of £28,000 to £30,000. He would give them in as few words as possible all the information in their possession respecting the arrangement with the Government for the transfer of the property of the Company. It might have been reasonably supposed that long before that date the Directors would have been in a position to give the full particulars to the proprietors, but delays were inevitable when international negotiations had to be conducted. He could say, however, that the Board had not been responsible for any delay that had occurred, for they had offered every facility in their power to the Government, and had acquiesced in every suggestion that the Government had made consistently with their not sacrificing the interests committed to their charge. He would ask them to bear in mind that throughout the whole of the negotiations the Board had not been in the position of a free agent. Their hands had been, so to speak, tied. So soon as the Governments concerned—that was to say, the English, French, and Belgian Governments—had decided to take into their own hands and to work the telegraphic system between this country and the Continent, the Company lay under a sentence of death; for not only its rights and authority ceased, but, what was still more important, a considerable portion of their property would have had no value unless it could be transferred to those who were about to conduct the traffic heretofore carried on by the Company. In March of last year they received a letter from the Treasury offering certain terms of purchase, which were generally that the Government would take over the whole of the employés with the exception of seven, as well as the whole of the Company's property at a valuation, save what were known as the Deolin and Salcombe cables. The Directors did not consider that in some respects the terms offered were adequate, but having regard to their position they had no option but to accept them. They, however, urged on the Government that it should reconsider its decision concerning the Deolin and Salcombe cables, and he believed he might say that he had an assurance that there would now be no difficulty in connection with those cables. At a recent date, however, they received information from Her Majesty's Government to the effect that it was under a convention with the French Government either to purchase cables

Digitized by Google

or lay them down jointly, and that the French and Belgian Governments had not seen their way to accept the principle of arbitration. The French Government proposed as an alternative course of action that an independent valuation of the cables belonging to the Company should be made by the officials of the French and Belgian Governments, and also by those of the English Government, and that they should have access to the books of the Company. It was very difficult to estimate what the result of that valuation would be; but they had received the most positive assurances, both from the English and French Governments, that they would deal with the Company in a spirit of equity, and he hoped that by the 31st of March all the arrangements would be satisfactorily completed.

The **Hon. Ashley Ponsonby** seconded the motion.

Mr. Soden animadverted upon the action of the Government in bringing pressure to bear on the French Government with the object of not renewing the Company's concession.

The **Chairman**, in reply to questions, pointed out that the Directors could have adopted no other course than they had followed, and that it would have been an act of suicidal folly if they had taken up a position antagonistic to the French and English Governments, who were masters of the situation.

The report was adopted, and the dividend recommended was subsequently declared.

CITY NOTES.

Electric Supply Corporation.—Letters of allotment and regret in the London Electric Supply Corporation have been sent out.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the week ended February 22 amounted to £5,927.

Change of Address.—The Endolithic Ivory Company have removed from 24, Well-street, Jewin-street, to Pomona-buildings, Fore-street, E.C., adjoining Moorgate-street Station.

Lancashire and Cheshire Telephonic Exchange Company, Limited.—An interim dividend at the rate of 7 per cent. per annum has been declared by this Company for the half-year ended December last.

Western and Brazilian Telegraph Company. — The traffic receipts of this Company for the past week, after deducting the fifth gross earnings payable to the London Platino-Brazilian Company, were £4,884.

Stock Exchange.—The Stock Exchange Committee have appointed Tuesday, March 5, a special settling day for Metropolitan Electric Supply Company, Limited, shares Nos. 6,101 to 50,000; the Eastern Telegraph Company, Limited, new ordinary shares, Nos. 380,001 to 400,000. The committee have ordered the following securities to be quoted in the official list: The Eastern Telegraph Company, Limited, 20,000 new ordinary shares, Nos. 380,001 to 400,000; the Metropolitan Electric Supply Company, Limited, shares Nos. 6,101 to 50,000.

Submarine Telegraph Company.—The report of the Directors of the Submarine Telegraph Company, Limited, for the six months ending December 31, 1888, shows a net sum which enables the Directors to add the usual proportion of the receipts to the reserve fund, to recommend a dividend for the half-year at the rate of 16 per cent. per annum, and to carry over a balance of £629. The dividend paid for the corresponding period of 1887 was at the rate of 15½ per cent. per annum. The number of messages transmitted during the six months was 1,846,002, containing 20,328,271 words. In 1887 there were transmitted 1,695,860 messages, containing 18,701,557 words. The average length of messages in 1888 was 11·01 words, against 11·03 words in 1887. The receipts of the half-year show an increase of £3,887 over those of 1887, and the expenses show an increase of £1,283. This increase is stated to be principally caused "by the insertion of much new cable when repairing several of the cables interrupted in the half-year, and by the thorough overhaul and repair of the steamer in the first six months of 1888." The report concludes as follows, no reference being made to the recent allegations as to a hitch in the negotiations with the Governments of England and France: "The proprietors are no doubt aware that the Company's concessions and agreements with the Postmaster-General and with the foreign Governments expired on January 12, 1889. The Directors have to report that the respective Governments agreed to allow the Company to continue working their own cables, as well as those belonging to Her Majesty's Government, until March 31, 1889. No arrangement has yet been definitely arrived at between the Directors and the Government for the acquisition of the Company's property, but considerable progress has been made, and, as the Government has decided to take over the property on April 1, the matter cannot be much longer delayed. The Directors would have been glad to submit for the consideration of this meeting definite terms of agreement with the Government, but at the date of this report they are unable to do so."

PROVISIONAL PATENTS, 1889.

FEBRUARY 18.

2854. **Improvements in electric light fittings.** David Urquhart and William Bates, 6, Westminster-chambers, Victoria-street, S.W.

FEBRUARY 19.

2885. **Improvements in methods and apparatus for charging secondary batteries or electrical accumulators.** Ralph Henry Christopher Nevile, Wellingore Hall, near Grantham.

2906. **Improvements in microtelephonic apparatus, which improvements consist partly in the use and employment of fluids as a medium to impart vibratory motion by means of sound, and currents of electricity.** Robert Henelade Courtenay, 6, Anerley-street, Battersea-park-road, Surrey.

2943. **Improvements in dynamo-electric machines.** Samuel Dickenson Williams, 8, Rutland-place, Newport, Monmouthshire.

2949. **Improvements in galvanic batteries.** Eben D. Cross, 45, Southampton-buildings, London. (Complete specification.)

2952. **Improvements relating to the transmission of electro-magnetic impulses for telegraphic and other purposes.** Henry Harris Lake, 45, Southampton-buildings, London. (Charles Emile Dressler, United States.) (Complete specification.)

2957. **Improvements in underground conduits and insulators for electrical mains.** Alexander Wilson, and Latimer Clark, Muirhead and Co., Limited, 3, Elm-court, Temple, E.C.

FEBRUARY 20.

3022. **An improved telephone mouth-piece.** Rocke Cotterell Greenhill Cottage, Crossmyloof, Glasgow.

3036. **Improvements in electric signalling apparatus for railway trains.** Alfred Julius Boult, 323, High Holborn, Middlesex. (William C. Johnston, junr., United States.) (Complete specification.)

FEBRUARY 21.

3089. **Electrical signalling, self-acting, and otherwise, on a railway.** George Prince and John Watkinson, 27, Albert-terrace, Alexander-road, Burley Fields, Leeds.

3103. **Improvements in electrical measuring instruments.** Walter Hibbert, 8, St. Dundas-road, West Kensington, S.W., London.

3130. **Improvements in or connected with gear wheels and bearings for magneto-electric call-bell apparatus for telephonic instruments, applicable also to other mechanism.** Harry Fraser, 47, Lincoln's-inn-fields, London.

FEBRUARY 22.

3163. **Improvements in electrical call-box apparatus.** Frederick Thomas Schmidt, Sunbridge Chambers, Bradford, Yorkshire.

3213. **Improvements in measuring instruments and electrical appliances.** William Edward Ayrton, 2, Upper Phillimore-gardens, and John Perry, 10, Penywern-road, both in London.

FEBRUARY 22.

3263. **Improvements in the mechanical construction of electrical dynamos.** George Richards, Broadheath, near Manchester.

3272. **Improvements in or relating to electric motors.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Westinghouse Electric Company, United States.)

3273. **Improvements in or relating to dynamo-electric generators.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Westinghouse Electric Company, United States.)

NOTES.

Madrid.—The defective state of the plant in the Madrid theatres has resulted, it is stated, in the town deciding to authorise a central station.

Forchheim.—A central station for 30 arc lamps is to be erected at Forchheim, in Germany, the power for which will be obtained from the neighbouring river.

Newcastle.—The applications of the two companies applying for licenses have been granted, with a stipulation prohibiting transfer to other companies at a profit.

Telegraphs to Persia and India.—We are informed that the Indo-European Company's communication with Persia and India and the Far East is temporarily interrupted.

Danish Cable.—The submarine cable from Calais to Denmark is at last repaired. The bad weather has obliged the steamer on several occasions to run into the Thames and various Dutch ports for shelter.

Sale.—We have received the catalogue from Messrs. Wheatley Kirk, Price and Goulty of the sale of electrical plant of the "Sun" Works, which is to take place on March 13, on the premises, at 11 a.m.

The Institution.—The next meeting of the Institution will be on March 14, at 8 p.m., when the discussion on Prof. Forbes' paper, "Some Electric Lighting Central Stations in Europe, and their lessons," will be commenced.

Bath.—The resolution of the Urban Authority that the wires should be placed underground, has been referred to the Electric Lighting Committee. Fewer standards will now be required, and these will be provided by the company.

Birmingham Exhibition.—The organisation of the Electrical Exhibition at Birmingham is progressing favourably, and is being well taken up by electrical engineers. The whole of the power for moving machinery will be supplied by means of electric motors.

Piccadilly Electric Railway.—Notice of motion has been given in the House of Commons by Mr. Bensor, Mr. Gainsford Bruce, and Mr. John Kelly, that the Bill empowering the construction of a subway between Piccadilly and Holborn-circus for electrical trains be read a second time that day six months.

Edison's Eyes Injured.—The New York *Mail and Express* states that Mr. T. A. Edison has been badly injured in the eyes by chemicals during an experiment. Colonel Gouraud has received a telegram from Mr. Edison, saying that the accident is not expected to have serious results, and that he is progressing favourably.

Pumping.—Plant has been fitted up whereby a supply of water is raised for Kingscavil-cottages, near Linlithgow, from Kingscavil Quarry, by means of an electric motor, the dynamo generating the current being at a distance of a mile and a quarter. The water is forced to a height of 135ft. to the reservoir, through 600 yards of 2in. pipes.

Portsmouth Harbour.—A new railway platform has been erected at the north railway jetty in Portsmouth Harbour for the Queen's use. The covered platform is 500ft. long, and on Tuesday it was lighted by electricity, the lamps being fed from the dynamo on board the "Victoria and Albert," which was berthed alongside the jetty.

Electric Light at Pekin.—The exhibition of the electric light, during the last few weeks, has been a source of considerable wonder and observation to the natives at Pekin. The light, which is intended for the palace, has been on view in Legation-street, and has attracted crowds of people to see it, including some of the Ministers from the Tsung-li Yamên, and officials from the palace itself.

The Julien Storage Battery.—The Julien Electric Company state that they have over 10,000 accumulators now in actual use by their customers, showing a great development of storage in America. A speciality is made of a 25lb. cell, with a capacity of 400 watts. A large demand for batteries is now arising for storage cars, but the largest number at present have been for electric light stations and installations.

Proposed Electric Railway in India.—Colonel Thomason, R.E. (says the *Indian Engineer*), is busy surveying the country between Naini Tal and the plains, at his own cost, with a view to the construction of an electric railway, for which he considers the available water-power, furnished by the lake, now running to waste, sufficient and to spare, and with which he proposes also irrigating a very fine site now lying idle for want of water.

Incandescent Public Lighting.—The Heisler Company have secured a contract at East Portland, Pacific Coast, in severe competition with the gas company, for 125 lamps of 30 c.p. for lighting the public streets. The circuits are 12 miles in length, and the lighting is pronounced very satisfactory by the Council. This is well on to a total of 20,000 lamps supplied by this company for public and private lighting by 30 c.p. incandescent lamps in American towns.

Town Lighting in France.—Quite a number of small towns in all parts of France have adopted the electric light. The latest addition is the town of Hennebont, Morbihan, the Municipality of which has granted a concession for 30 years to MM. Bonnefant et Cie., electrical engineers. The public lighting will comprise 6 arc lamps and 80 incandescents of 16 c.p.; the inhabitants of the town have also subscribed for 500 other lamps which are to be charged for by meter.

Telegraphic Money Orders.—Mr. Henniker Heaton asked the Postmaster-General whether there was likely to be much further delay in introducing into this country the telegraphic money order system which has been adopted on the Continent and in the Australian colonics. Mr. Raikes said that he was glad to be able to state that he hoped very shortly to announce to the House the date on and from which telegraphic money orders will be introduced by way of experiment in this country.

Launch of the "Peral."—The first trial of Lieutenant Peral's electric submarine vessel took place at San Fernando, near Cadiz, on Wednesday. Thousands of enthusiastic spectators witnessed the experiments. Telegrams state that the vessel worked well on the surface, but that a portion of the machinery became heated, and the tide carried the vessel into shallow water, where she grounded. She was got off, however, and returned to the arsenal. A submarine trial will take place shortly.

Electricity in Newspaper Offices.—Mr. Horace Cox is, we hear, intending to light the new *Field* and *Queen* publishing offices, Bream's-buildings, Chancery-lane, with

Digitized by Google

the electric light throughout. To no business is the light more applicable than to that of printing and publishing, and it would be advisable that other newspaper offices should follow his example. When they are also able to realise practically the extreme suitability of the electric motor to printing, our happiness in life will be fairly complete.

Joel and Co.—We learn that business arrangements have been made by Mr. Henry F. Joel with Mr. W. Potter, A.M.I.C.E., who will henceforth work in conjunction with the firm. Mr. Potter takes up his residence at Barnet, presumably to give personal attention on the spot to the pioneer work of incandescent public lighting. Messrs. Joel and Co. have just lighted the Wholesale Co-operative Stores, Leman-street, E., with 200 lights, and have been busy for some time with some pretty extensive electric lighting among the mills in Scotland and the North of England.

Harrow.—Another public meeting was held at Harrow on Thursday, the 28th ult., on the public invitation of Messrs. W. F. and F. Taylor, when a fairly large number of ratepayers attended. Messrs. Taylor expounded their scheme in opposition to Mr. Crompton, and gave details of cost, and representatives of the Westinghouse and the Gaulard-Gibbs system also addressed the meeting. Resolutions were proposed stating that it was advisable that the electric light should be introduced, and the formation of a committee was proposed; but the proceedings became unbusinesslike, and the audience left before a committee could be appointed.

Chicago.—A large central station is now working in Chicago on the Edison system, with 17 miles of underground mains. The station has a capacity of 80,000 16-c.p. lamps, of which 13,000 are now connected. The building has been specially designed by one of the leading architects, and is thoroughly fireproof throughout. There are to be 36 Edison dynamos of 600 amperes, and eight of these are now installed, and in operation. A large amount of current is also disposed of for motive purposes with excellent success, the power being applied to various uses, such as printing presses, elevators, ventilators, pumping, manufacturing, and a large number of miscellaneous industries.

New Wood Casings.—Mr. Samuel Elliott, of the Albert Moulding Mills, Newbury, is again well to the fore with a catalogue of wood casings for electrical contractors, which we should advise our readers to write for, comprising a large and varied assortment of sections of casings, covers, and cleats for electric light wires. These are beaded, grooved, and moulded in shapes either to harmonise with the elaborate wall decorations of mansions or for the simplest factory work. The designs of many of them are arranged so that they can be run as chair-rails round a room, or as ceiling mouldings, omitting the grooves for wires when necessary. The casings are worked in American whitewood, oak, mahogany, teak, walnut, pitch-pine, yellow deal, or other woods as desired.

Memorial to Gaulard.—The Council of the Società Italiana di Elettricità has taken up the proposal embodied in a letter from Sig. Piazzoli to Sig. Bignami, director of the Rivista *L'Elettricità*, to present, in honour of M. Gaulard, some suitable token of the high appreciation in which that gentleman's efforts on behalf of science are held in Italy. In that country the practicability of the useful transmission of electrical energy was first proved in 1884, when the Lanzo station was electrically lighted by energy generated at Turin, 24 miles distant; and it is thought that the encouragement then given by Italy to the new system entitles their representative society to take the initiative in asking subscriptions for the purpose of recording, in the form of a memorial tablet, the perfect success of the early experiments with the secondary generators. Communications or subscriptions may be forwarded to Sig. Wolf, Cassa di Risparmio di Milano.

Halifax Mutual Lighting.—We have several times recommended the adoption of a scheme of mutual benefit for users of electric light and power in various localities, and we are glad to see that Halifax is promising progress in this direction. The Halifax Mutual Electric Lighting and Supply Company, we hear, are in negotiation with the Corporation to obtain their permission to light a large area in the centre of the town with electricity, and to enable them to do this they ask liberty to cross the streets with overhead wires. The company, which is formed largely of gentlemen who intend to use the light on their own premises, has received large support from persons who intend to take the light, and the capital required will, it is understood, be at once subscribed. It is the intention of the company to give all consumers an opportunity of acquiring an interest in the company so that the benefits to be derived may be made as mutual as possible.

A Gas Company's Electric Station.—A very fine specimen of electric light station, undertaken by the local gas company, has been opened at St. Paul's, Minnesota, U.S. The station is run on the Thomson-Houston system, and the engines, which are of the Corliss type, have a capacity of 2,500 h.p. There are four long lines of shafting, carefully arranged, with heavy foundations, one behind the other on the ground floor, fitted up complete with Hill friction-clutch, pulleys, and couplings. The main belts run underneath the flooring and out of the way of the line of shafting. The dynamos are on the second floor, and the friction clutches can be worked from either above or below. The dynamo belts run upwards, and hang on the dynamo pulley, giving the heavier contact on the smaller pulley. The station is a very successful installation, and is a sample of the sort of enterprise on the part of gas companies that we should like to see extend.

Barnet.—The plant at Barnet is being extended by the addition of two 50 actual h.p. Royal Mail type Tangye engines, and two 50-h.p. boilers by Frazers, of Bow. The dynamos will be Joel dynamos. We believe that although Mr. Joel has quietly taken what blame has been given for the difficulties occurring at the opening of the electric light at Barnet, the makers both of the dynamos and the lamps have been largely to blame in the matter, both through inferior workmanship and delay. Mr. Joel alleges that the Bernstein lamps were months overdue in delivery, and were not all of the ordered candle-power; while the Statter dynamos proved very far from satisfactory in their working, and will be discarded. Troubles introduced by the neglect or delay of contracting manufacturers are extremely unfortunate, as there are quite sufficient difficulties to contend with in introducing a new system of lighting into English towns without interior difficulties to deal with.

Control of the Submarine Cables.—In the House of Commons on Monday, in answer to a question by Sir R. Fowler, Mr. Raikes said: I am glad to be able to state

Digitized by Google

that the negotiations with the Governments of Germany, Holland, Belgium, and France, which have been in progress for several months past, are now nearing completion, and I have now every reason to hope that the working and the maintenance of the cables between this country and those named will, after an early date, be entirely in the hands of the telegraphic administrations of the five Governments. A uniform rate of 2d. per word with a minimum will be charged—a reduction in the case of Germany and Holland of 1d. a word, and in the case of France of ½d. per word. At the same time, negotiations have been proceeding and are well advanced between the Governments of France, Belgium, and this country for acquiring from the Submarine Telegraph Company the cables now their property between England and Belgium and France, and by the Government of this country for the transfer of the officers of the Submarine Company to the service of the Post Office, and the acquisition of the offices, cable ship, stores, etc., by the Post Office.

Humboldt Electric Power.—The statutory meeting of the Humboldt Electric Power and Mining Company, Limited, was held on the 28th ult., at the offices, 63, New Broad-street, E.C., under the presidency of Sir W. Guyer Hunter, K.C.M.G., M.P. (the chairman of the company), when it was reported that satisfactory progress had been made, and that shares were now being offered at a premium. Mr. Alfred E. Ann, the managing director, in giving particulars as to the working, said that the subject of the employment of electricity for these purposes was attracting a good deal of attention both here and in America, and he believed also in Africa, and the firm from whom they had received the last tender among those referred to by the chairman, had already supplied the great Comstock with an electric system which was said to be working most satisfactorily. The firm in question had tendered for this company's work, and was some thousands of pounds lower than the first tender received. Thus, although they had regretted the delay, they had really saved considerably by waiting. It was hoped, in four or five days, they would be able to cable out the order for the proceedings at the mine to commence. It was found that the distance from the river to the house of Mr. R. K. Colcord, the engineer, was just over 12 miles. They had found there was more water power than they had expected and represented, in the dry season, a gross h.p. of about 460, so that if they only took a quarter of it, it would be plenty for their first operations. He did not think it would be advisable to attempt to crush much ore before electric power was applied. He expected the electric plant would be erected in another month or two.

Electrical Type-setter.—Mr. Samuel Story's "Notes of an American Trip," now appearing in the *Sunderland Echo*, has an interesting account of type-setting by electricity on the *New York Tribune*. He thus describes it: Imagine my surprise when, on entering the composing-room, I found—*no type*. None; except a very limited quantity of large, odd sizes. How, then, is the paper set? By machines—electrical machines. There they stood in a row, 30 grim, silent demons. At the turning of a little handle they are instantaneously full of life. Each has a keyboard like a piano, and in front of the operator a series (105 in number) of oblong tubes like the attenuated reeds of a miniature organ. These hollow tubes are about 2ft. in length, as broad internally as type is high, and with a frontage as large as the type is thick. Each is fitted with brass squares, with a section cut out in a series of slots or nicks. Each letter has its own series of nicks on the inner edges of a V-shaped groove, and a square-edged space at the side where is the matrix or reverse of the letter. The operator, sitting with the copy before him, touches the keys, and each letter falls in due order till the line is complete. Two steel fingers seize this, push it along, space it and justify it. Again two fingers seize it, and push it in front of a little cistern full of molten lead. As it reaches its place, the machine pushes out from the cistern a layer of lead line-long and type-thick. The faces of the cooling lead and the brass edge come into contact, the matrix letters are impressed as positives on the lead, and there remains a solid line of type. This goes in due course to the galley, and the columns and pages are made up and stereotyped in the ordinary way. Meanwhile, the machine whisks the brasses up to a series of little waggons running on an endless wire above the tubes, and as each brass reaches its own nicks it drops into its tube and is ready again for use. It has only been out of its nest one-third of a minute at the utmost. As a consequence, few brasses are needed. The letter oftenest used, e, has only 16. I could carry the whole complement for a machine in my coat-pockets. "And what will a machine perfect?" said I. "One machine, with one man only, will set 5,000 ems an hour," said Mr. Lyman, "and do its own distributing. And there is no waste of type, no wear and tear. It is equal to six men." "Do other papers use it?" "None in New York; a few in the country, where they don't compete with us, and are owned by our friends." "And England?" "None in England *as yet.*"

Public Lighting at Brussels.—The commission appointed in Brussels to consider the question of electric light at its last meeting determined that the installation should not be undertaken by the Municipality out of the rates, but should be the subject of a concession to a private company under regulation from the Municipality, the town to have the right to purchase the installation in any specified time. Propositions for the concession must be received by the 1st of July next. The following are the principal conditions: The undertaking must include the erection of stations, and the running of mains to the houses of the streets, shown on the plan prepared by the Municipality. The service must be available for both electric light and power, but the contractors may choose their own system. They can use either a low-tension system of one or several stations, or a high-tension system of transformers or accumulators, or a combination of these. Ground for low-tension stations could be obtained at 500f. per square metre near the Pavilion Nord and behind the Eden Theatre. If for high-tension currents, grounds at a greater distance can be obtained at a cheaper rate. All the installations must be so arranged that the output could be doubled without further purchase of land, and the sites must therefore be sufficiently large at first. Among the first applications the town will take 120 arcs of 12 amperes for the Boulevards, 600 amperes for the lighting of the Theatre Flamond, and 80 arcs for the Parc and other places. The contractors, among other things, will be required to state how they will ensure a constant difference of electric pressure in the mains; the amount of insulation they guarantee; the method of laying the cables and of making house connections; and the prices to be charged for current. The mains can be laid either under the pavement or the road, or within the large-sized sewers which run down nearly the whole of the principal streets of Brussels and the suburbs. In the boulevards Anspach and du Nord, and

Digitized by Google

in the Rue des Fripiers, the mains must be laid down each side. Besides exact details of the charge for current to customers, the tenders must also give the cost of all conduits, wires, fittings, and apparatus necessary for the introduction of the light into private houses. The length of the concession will be strictly limited. Every assistance will be given to the extension of the distribution to the suburbs. The salaries of the officials provided by the contractors will be paid by the town, at a scale not exceeding that indicated in the tender. The contractor himself to direct the management of the undertaking, or to delegate engineers capable of carrying it on. In addition, the book-keeping, and the whole working of the station, is to be subject to the general control of the town for the period of two years.

Arc Lamps.—The clear and ab'e exposition by Prof. Thompson on "Arc Lamps and their Mechanism," at the Society of Arts on Wednesday, was listened to with extreme interest by a very crowded audience, and, as Mr. Percy Sellon remarked at the close, was characteristic of Prof. Thompson's lectures in not being a mere *rechauffé* of old descriptions, but a new grouping, with the enunciation of ideas from which everyone might learn. The division of arc lamps into three groups—namely, the Continental or clockmakers' lamps (rack adjustments), the Yankee or sewing-machine lamps (clutch lamps and others), and the British or engineers' lamps (with mechanical or friction-feed)—was vastly appreciated. Some of the audience testified to the excellence in practice of the so-called sewing-machine lamps, seemingly rough and "thrown together," but which acted admirably in practice. Mr. Preece, who acted as chairman, pointed out, however, that when the streets of the City of London—and probably also the Strand and Piccadilly—were lighted with thousands of arc lamps, something which would act better than those which satisfy a newly-built American city would be required in the first metropolis of the world, and all the ingenuity of lampmakers would be called into play for the production of a perfect lamp. In the lecture Prof. Thompson illustrated and described the older forms of arc lamps, described and showed the Brush, Thomson-Houston, Crompton, Siemens, Fein, and other lamps, and referred with great favour to the Brockie-Pell arc lamp, saying that Mr. Brockie had run the gamut of all arc lamp constructions, and produced finally, with Mr. Pell, a lamp which he thought ought to be far more widely known and used. He also testified to the good working of the lamp (Newton's), in which the feeding is secured by the waggling of a wire scratch-brush, which presses obliquely upon the carbon rod, gradually forcing it downwards. The lamp to which Prof. Thompson gave the greatest praise was a new one devised by Macquaire, now introduced by the Planet Manufacturing Company, 2, Victoria-mansions. This was exhibited, for the first time in England publicly, on the occasion of this lecture, though it has been tested at the Kensington Court station, and its action, as shown by means of an object-glass reflecting the arc upon the scene, gave the nearest approach to a perfect regulation hitherto produced. The lamp really should belong to a fourth category, and be called an electrical engineers' lamp, for the regulation is obtained by the action of a small electric motor, whose field-magnets are the series-coil, and whose armature is the shunt to the current. The action is so arranged that the motor turns one way or the other, according to the dip of a small arm acting upon the brushes of the little motor. The result is an arc lamp working in any direction, feeding by almost infinitesimal portions, practically silent, and maintaining an arc more regular in its formation than even the text-book cuts of the two arc carbons. It is, moreover, having the motor behind it, not open to liability to stick by dirt or friction, as will gravity lamps, and indeed it is difficult when working to hold the carbons apart. We hope to give a full report of Prof. Thompson's paper next week.

Electricity and the New Political Economy.—In the current number of the *Century Magazine* there appears an article by Mr. Charles Barnard, entitled "Something Electricity is Doing," an able exposition to the popular mind of the progress of electric motor engineering. In this article there occurs a passage, with which we are in the heartiest accord, referring to the influence of the motor upon the conditions of life in the future. Mr. Barnard says: "To the student of social science the electric motor is full of suggestions for the future. If power can be subdivided and conveyed to a distance, why may not our present factory system of labour be ultimately completely changed? People are huddled together under one roof because belts and shafts are so pitiably short. If power may traverse a wire, why not take the power to the people's homes, or to smaller and more heathful shops in pleasanter places? To-day we find sewing-women crowded into a hot, stuffy room, close to the noise, smell, dust, and terrible heat of some little steam-engine at one end of the room. The place must be on a low floor because of the weight of the engine and the cost of carrying coal upstairs. Let us see how the work may be done with motors. We may take the elevator in a wholesale clothing warehouse on Bleecker-street and pass through the salesrooms to the top floor. The building is lofty and of light construction, and yet we find in the bright and pleasant attic above the house-tops a hundred girls, each using power. They are seated at long tables, each one having a sewing-machine, and secured to the under side of the table is a small electric motor, one to each machine. The operator has only to touch a foot-pedal and the motor starts, giving about one-tenth of a horse-power, at very high speed. If the speed is too fast, it can be regulated at will by the pressure of the foot on the treadle. There is no heat, no dust or ill-smelling oil, and only a slight humming sound, the sewing-machine itself making more noise than the motor. The room is sweet, clean, and light, and it is in every respect a healthful workroom. If we look out of the window we see two insulated wires passing under the sash down to the electric light wires on the poles below. There are people who cry out against the overhead wires, and would pull them all down. Some day they will be buried underground. Meanwhile, is it not an immense gain for these working girls to be placed in a quiet, sunny room, far from the maddening engine? In another shop on Broadway we may see a different arrangement. A 2 h.p. motor takes its current from an electric light wire in the street, and redistributes its power to shafting placed under the work tables. Each operator with a touch of the foot throws her machine into gear, and takes her share of the 2 h.p." This condition of things admirably illustrates the effect electricity will tend to have upon the life of the workers. We believe, indeed, that the motor arrives just at that juncture when the pressing condition of modern work requires it, and the electric motor, it will be found, in the near future will inevitably create an industrial revolution greater even than that of the introduction of the steam-engine and the rise of the cotton system.

ELECTRICAL MEASUREMENT.*

BY PROFS. W. E. AYRTON, F.R.S., AND J. PERRY, F.R.S.

(Verbatim report of the abstract of the Paper given by Prof. Ayrton at the meeting.)

(Concluded from page 177.)

For the purpose of ascertaining the exact law of variation of the effect of a layer of wire with its distance from the axis of our ordinary magnifying spring instruments, and the right depth of wire to put on, we had one of these instruments—the one on the table—wound with eight separate layers of copper wire 83 mills. in diameter, covered to 97 mills. Each layer contained the same number of convolutions, and we could send the current through only one layer, or through only two or more layers in series. The various sets of curves which I hold in my hand gives the results of a long series of experiments made with this instrument by Messrs. Fossett, Horne, and Jacob, three of the third year students at the Central Institution. The first set of curves shows the current required to produce any particular deflection when any one of the eight layers is used, the second set when either layer one is used, or layers one and two in series, or layers one to three, one to four, one to five, one to six, one to seven, or all the eight layers; the next set the watts absorbed to produce any particular deflection when the same sets of layers are used, and the interesting result comes out that if all the eight layers be used, it requires the greatest expenditure of watts to produce any particular deflection, whereas if only layers one and two it requires the least expenditure. In this set of experiments layer one alone was not used, as it heated too much when the maximum deflection was being produced. The next set gives the ratio of watts expended to cooling surface of the bobbin if only wound with the particular layers employed in the experiment; and now the results are reversed, for although there is the least expenditure of watts to produce any particular deflection if only layers one and two be used, the ratio of watts to cooling surface is the maximum, whereas for layers one to eight inclusive the ratio of watts to cooling surface is a minimum—in fact, the cooling surface obtained by winding the wire to a greater radial depth increases more rapidly than the watts expended in producing any particular deflection. Hence the increase of radial depth which we effected some time back in our magnifying spring instruments was a beneficial change, since, although it increased the actual expenditure of power, it diminished the rise of temperature of the instrument which occurs when the current is allowed to pass for some time.

The last set of curves is an extremely interesting one, as it led to a result that we were not looking for. In this series the observations of the true value of the current and the corresponding deflection was made with a gradually increasing and then with a gradually decreasing current, and it was found that the percentage difference in the readings for an ascending and a descending current depended on which of the layers of wire were being employed. If the outside layers were used the residual magnetism error was less than if the current was sent through the inside one. I suppose that was due to the fact that the residual magnetism of the iron tended to send its lines of force in one direction, while the current when flowing in a coil of large diameter would send them in a somewhat different direction; but there was no doubt of the fact that we got a different amount of residual magnetism error when different layers were employed: the instrument was better, in fact, when used with certain layers than when used with other layers. The general conclusion was that the permanent magnetism error for an ascending and descending current was the greatest when layers one to five, nearest the core were used, less when layers one and two were used, still less when layers one to eight were employed, and the minimum error was obtained when the current passed only through the outside layers, seven and eight. It seems to be a question of the difference between the shape of the field due to the coils, and the shape of the field due to the residual magnetism in the iron.

* Paper read at the Physical Society, February 23, 1889. Prof. Reinold, F.R.S., in the chair.

But whatever the explanation may be, the important fact remains that *the permanent magnetism error of a given piece of iron, when used in a measuring instrument, can be varied in amount by varying the diameter of the coil.*

STANDARD INSTRUMENT OF WIDE RANGE.

The next point, perhaps, that has to be considered is what is the best way to make for a laboratory a cheap arrangement which will measure very accurately a very large range of currents. Of course, Thomson standard instruments can be bought for measuring from one small fraction of an ampere to some other fraction, and so on. But suppose a laboratory wants to measure with considerable accuracy currents from ·01 to 600 amperes, how can it be done? One way is to purchase a dozen standard measuring instruments, costing perhaps two or three hundred pounds. But suppose the funds do not allow of such a great expenditure, how can the same result be obtained? It can be obtained in a very simple, and certainly far cheaper, way; and the plan that we adopt at the Central Institution is to use a voltmeter with a wide range of variable sensibility to indirectly measure currents. We send the current to be measured through a fairly large and thick sheet of platinoid, such as the sheet before you, which is the substance having the smallest temperature coefficient: we are now using leaves of platinoid parallel with one another so as to get still great surface. We assume that the currents are such as not to alter the resistance of the sheet by any appreciable amount. The instrument used is, as I have said, really a voltmeter, which is attached to two fixed points by means of wires soldered to two definite points of the platinoid, and the voltmeter we employ is a d'Arsonval galvanometer, by which the difference of potential between two fixed points in the platinoid is measured, and you see that by altering the resistance in the voltmeter circuit you obtain an enormous range of sensibility. If the instrument is calibrated so that when it alone is a shunt to the sheet of platinoid, one ampere gives a deflection right across the scale of 600 divisions, then by inserting known resistance the sensibility of the instrument is at once diminished in any definite ratio we like without any other absolute calibration being necessary, assuming that the platinoid does not change its resistance by the passage of the current. It is by that means possible to obtain a complete deflection right across the scale for one ampere, or for some hundreds of amperes, or for anything between; and if you want to measure 1, 10, or 50 amperes to $\frac{1}{500}$th, it is done by the introduction of a known resistance, and the sensibilty is at once changed in a certain definite ratio. The d'Arsonval coil is not heated by the passage of the current. At first we were desirous of making direct-reading scales to be used with large range of current, and of making the arrangement such that, instead of having to calculate what 100 divisions meant, a new scale could be put in place of the old scale, and the current could then be at once read off in amperes, milliamperes, deca-amperes, or deciamperes corresponding to the different resistance put in. But the difficulty we met with was that with the ordinary d'Arsonval galvanometer, the deflections, in spite of the very small angle through which the coil moves, are not proportional to the current. If you start from the centre so that the plane of the coil is along the lines of force when no current is passing, the deflection is proportional to the current; but if you start with the coil deflected, so that the spot of light is at one extreme end of the scale for no current, you find, on carefully calibrating the instrument, that you get a broken straight line consisting of two straight lines meeting at an angle, or, probably, strictly, meeting according to some curve at about the spot corresponding with the plane of the coil, being parallel to the lines of force. Hence there is a difficulty in subdividing the scale uniformly, and this difficulty is met with even when the plan, as proposed some six years ago, of using curved pole pieces is employed. This puzzled us for a very long time. It occurred to us that the effect might be due to the torsional wires being so placed in the ordinary d'Arsonval instruments that there is practically no twist in them when the plane of the coil is along the lines of force and the spot of light is in the middle of the scale. In order to send the spot of light to one end, the top or the bottom

Digitized by Google

suspension has to be turned, and as in the ordinary d'Arsonval galvanometers the bottom suspension cannot be twisted round, the spot of light is brought to the end of the scale for zero current by turning the top suspension through twice the angle turned through by the coil. Hence, at the new position at one end of the scale both the bottom and the top suspensions have a twist in them in opposite directions, of an amount equal to the angle through which the coil has been turned from the symmetrical position. Now, we thought that the calibration curve, being a broken straight line, might in some extraordinary way be due to the fact that under these circumstances, when the coil passed through the zero position, the direction of twist on the bottom suspension became reversed, but neither theory nor a number of experiments bore out this idea, which had to be abandoned, and, finally, we arrived at the conclusion that the peculiar result was due to the centre of gravity of the coil not being exactly in the axis of suspension. Hence, the coil was taken down and more accurately resuspended by Mr. Smith, a fourth-year student at the Central Institution. But we found, no matter how accurately he balanced the coil, the break in the calibration curve could not be entirely removed. Finally, however, after much experimenting, our assistant, Mr. Bourne, to whose dexterity of hand and fertility of resource we are much indebted, solved the problem by suspending the coil by a single torsional suspension from the top, and arranging an extremely elastic non-directive suspension to lead out the current from the coil at the bottom; in fact, by obtaining practically a unifilar torsional suspension, at the end of which the coil hangs freely, with its centre of gravity strictly in the axis of suspension, he solved the problem. The result is that *the calibration curve of a d'Arsonval galvanometer so constructed and drawn to such a scale that it is about a yard long, fails to show any want of deviation from perfect straightness when tested by one of Sir William Thomson's balances, and when the length of the scale over which the spot of light of the d'Arsonval moves is about a yard long, subdivided into about 800 divisions.*

Time will not permit of my explaining to you the exact arrangements we have carried out at the Acme Works for rendering the change of sensibility perfectly automatic, so that it is impossible for the tester to be using a different sensibility from the one he believes he is using. Suffice it to say that currents varying from a fraction of an ampere up to 600 amperes, and P.Ds. from a fraction of a volt up to 500 volts, are all measured with one single instrument, and in no case, even for the smallest current or the smallest P.D. to be determined, is the deflection of the spot of light from the zero less than about 4½in.

For determining the absolute value of the deflection in amperes, we have usually employed the silver voltameter in the form recommended by Lord Rayleigh, the current density being limited to one ampere per six square inches of surface of the platinum bowl on which the silver was deposited. At first the results were not perfectly in accordance with one another, but this Messrs. Lamb and Smith, two of our students, who took up the investigation in a most praiseworthy manner, traced to the use of methylated alcohol and methylated ether for the drying of the platinum bowl after the silver was deposited in it. If the bowl was dried in a vacuum after the deposit of silver in it had been washed with distilled water, consistent results were obtained, and they found that equally consistent determinations could also be made by the employment of absolute alcohol without the use of a vacuum. After our d'Arsonval galvanometer had been finally calibrated, Prof. Rücker was so kind as to lend us one of Sir William Thomson's deci-ampere balances, and we found that a certain current measured by it was 4·708 amperes, whereas measured by our d'Arsonval it was 4·699, the difference being only one-fifth per cent. The result is interesting, as we understand that Sir William Thomson's balances are calibrated entirely with the copper voltameter, whereas the calibration of our standard d'Arsonval has been effected solely with the use of the silver voltameter.

Having arranged the d'Arsonval galvanometer so that we knew exactly the connection between the deflection and the current producing it, we observed, on comparing the readings of a Siemens dynamometer with the readings of the d'Arsonval, that the square root of the angle through which the spring of the Siemens dynamometer had to be twisted to bring the moving coil to the sighted position was not perfectly proportional to the current. As the spring of the Siemens dynamometer has some 50 convolutions, we could not at first imagine that the couple required to produce only one-half or three-quarters of one revolution was not proportional to the angle, and we felt that there must be some mistake in the experiment, such as the existence of some permanent field acting on the moving coil, and which would produce a couple proportional to the current, in addition to the action of the stationary coil on the fixed coil, which produces a force proportional to the square of the current. But as we obtained the same result with the Siemens dynamometer on reversing the direction of the current through it, there was no doubt that we had really placed it, as we had intended doing, in such a position that the plane of the moving coil when in the sighted position was perpendicular to the magnetic meridian at the place, and hence there could be no couple introduced by any permanent field. We had been under the impression that whereas the Siemens dynamometer, being a zero instrument, was not so convenient to employ as a direct reading instrument like our magnifying spring ammeter, which can be read from a distance, yet that the disadvantages of having to adjust this zero instrument for each current to be measured was compensated for by there being a perfectly exact simple law connecting the current with the angle through which the torsion head had to be turned to bring the moving coil to the sighted point, and it was not until Prof. Rücker was so kind as to lend us two of Sir William Thomson's meters that we felt quite sure that the small error of the Siemens dynamometer, which we felt our experiments had brought to light, had a real existence. We are most sorry to find that our conclusion is correct, and that the ratio of current to square root of the deflection of the dynamometer, or what is simply called the constant of the instrument, is not absolutely constant, but increases as the current is increased, due, we imagine, to a slight distortion of the spring, which occurs with a deflection of even 180deg.

We have tested five Siemens dynamometers, and find that in all cases the constant increases with the deflection up to a deflection of about 270, corresponding with 243deg. In some cases the constant appears to still further increase as the deflection increases. In others it appears to reach a maximum at somewhere about 240deg., and then to diminish again as the deflection is increased up to 360deg. The fact that the variation of the constant is regular, and not vaguely too high or too low, tends to prove that the result is not due to errors of observation. We append the results of the tests of two dynamometers to indicate the character of the result. Of course, this variation of the constant does not in any way prevent this instrument being of great service, especially for the measurement of alternate currents, but its existence should not be forgotten in the most accurate use of the instrument.

One Dynamometer.		Another Dynamometer.	
Deflection.	$\frac{\text{Current}}{\sqrt{\text{Deflection.}}}$	Deflection.	$\frac{\text{Current}}{\sqrt{\text{Deflection.}}}$
70	1·455	21·5	1·080
132	1·463	54·3	1·085
156	1·470	121·2	1·090
196	1·471	188·7	1·092
234	1·472	270·5	1·095
272	1·478	334·5	1·093
		406	1·091

In each case a deflection of 400 corresponds with a rotation of the milled head through 360deg.

Hot Wire Voltmeter.

I, lastly, come to another point which is also of considerable scientific interest. At the end of 1887 we brought before the Society of Telegraph Engineers a modification of the well-known Cardew voltmeter, which, as you are aware, can be used to measure either a direct or an alternate P.D. Our modification is a very simple one; instead of measuring the actual extension of a straight wire, as Captain Cardew has done, we measure the change of sag of the wire

Digitized by Google

by using one of our magnifying springs. Here is one of our instruments. The sensibility of the arrangement is very great indeed. What is measured is the change of sag in the wire, and you can see how very marked is the deflection by putting on two volts.

[Model voltmeter, with a magnifying spring attached to the centre of a wire fastened at both ends, shown in action. A potential difference of two volts applied at the terminals produced a rotation of the pointer through eight right angles.]

Length of Platinum Silver Wire 208 millimetres.

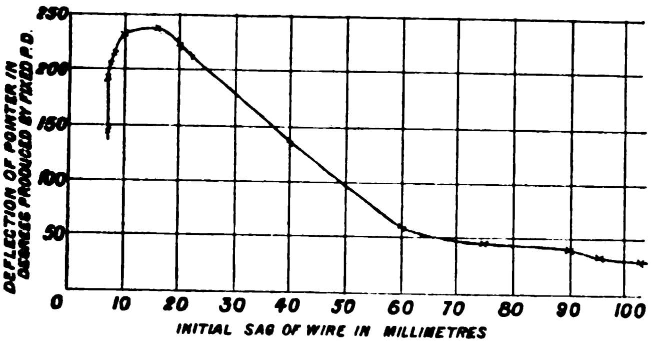

FIG. 1.—Experimental Hot-Wire Voltmeter.

At the time our hot-wire voltmeter was first shown we described what we believed to be the mathematical theory of its working, and it is in connection with that theory that we bring the instrument before you to-day. In our original paper, printed in the *Journal* of the Society of Telegraph Engineers, in which we gave the formula connecting the deflection of the instrument with the volts required to produce the deflection, we gave a calibration curve, determined theoretically, connecting the deflection with the volts required to produce the deflection. But we neglected the variation in the length of the fine platinum wire due to the alteration of stress as the sag altered—*i.e.*, we assumed that the wire expanded simply because it was heated, and we did not take into account the fact that when it expands and gets longer the stress is altered, and therefore the length of the wire is altered. This omission is the more curious since one of us had pointed out in the *Electrician* some months previously to that, that while the cooling of the telegraph wire in the winter diminished the length, and therefore the dip, the increase of stress caused an expansion, so that the whole change of sag in a telegraph wire which occurred with a change of temperature was not as much as it would have been had this change of stress not taken place, and we showed that this compensating effect enabled less sag to be used on telegraph wires in the summer than would be otherwise possible without the wires being broken in the winter.

We were under the impression, however, that the actual stress in the platinum silver wire in our hot-wire voltmeters was not sufficient to introduce a change in their sensibility in consequence of the alteration of stress that occurs with alteration of sag. Experience, however, has since shown that that is not the case, and that when the wire gets hot and expands, and the dip increases, the diminution of stress actually allows, as it were, a contraction of the wire, or, in other words, it does not expand as much as it would were there not this compensating action. This compensating action, which is very valuable to the telegraph-engineer, has the very opposite character for the constructors of our voltmeters, because it tends to diminish their sensibility. Mr. Bourne has made experiments, using the apparatus before you, in which there is a given wire, 208 millimetres long, fixed between two points, a given spring and pointer, but in which the amount of sag can be varied at will by simply moving these two arms; the wire remains the same in length, but the initial sag can be altered; the instrument is covered up, with the metallic cover to shield it from draught of air, and its calibration obtained. He also made experiments of the alteration of sensibility with sag for various magnifying springs and for various initial stresses in the spring, because, as the modification of our original result is due to the alteration of stress with alteration of sag, this modification will be different dependent on the initial stress on the wire. A number of curves are obtained, of which one is shown in Fig. 1, giving the law of alteration of sensibility with initial sag. From these it is seen that, instead of the maximum deflection being obtained for a given P.D. at the terminals of the wire when the initial sag is very small, the sensibility of the instrument rapidly increases as the sag increases up to a certain value, and then diminishes, but less rapidly, as the initial sag is increased. For each type of magnifying spring, and for a given initial stress given to the spring, he obtained a perfectly definite curve giving

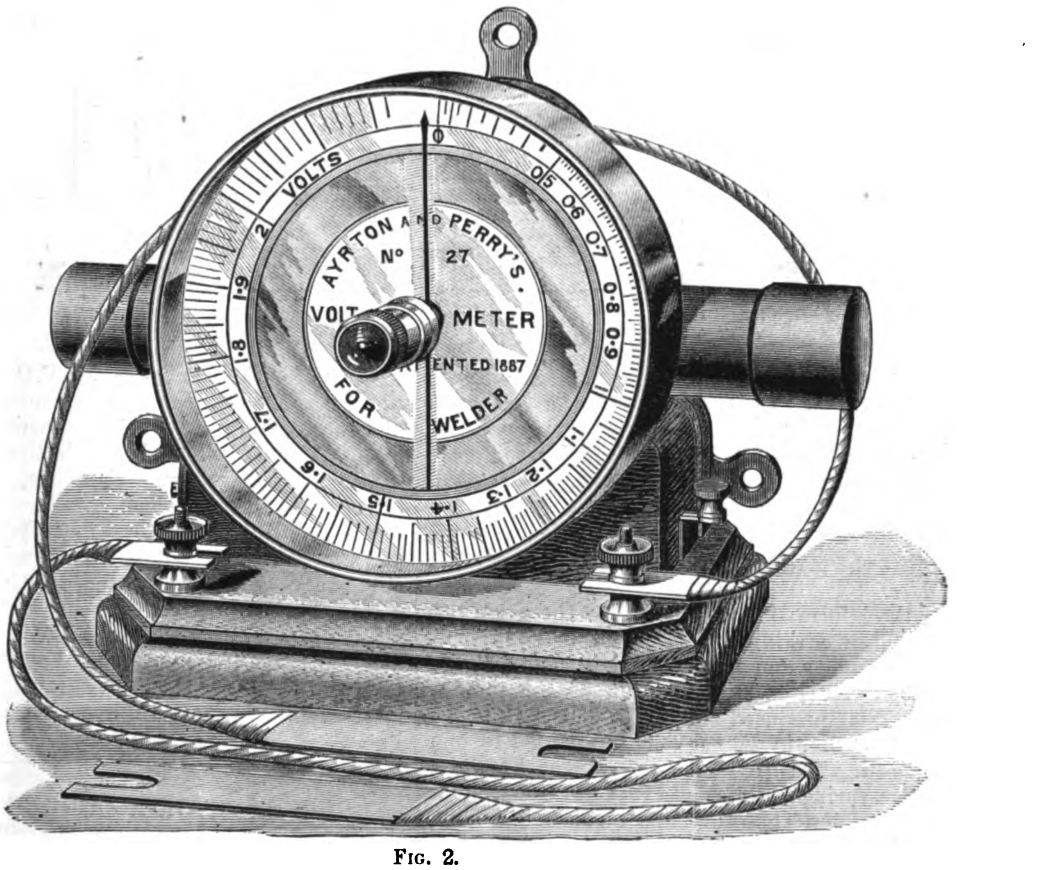

FIG. 2.

Digitized by Google

a maximum sensibility with a particular inital sag. These curves have the greatest practical value, because they show what initial sag should be given to the wire to obtain maximum sensibility; also what range is available for adjusting the sensibility of the voltmeter to adapt it to the direct reading scale by altering the amount of the sag.

Another thing came out regarding the temperature correction. Each hot-wire voltmeter should be so constructed that the zero does not alter when the temperature of the whole instrument is changed between the day and the night, or between the winter and the summer; also that a given P.D. produces the same deflection of the pointer whatever the temperature of the instrument as a whole. The tube, therefore, has to be composed of two metals, but the curious thing comes out that the coefficient of expansion of the tube, to get perfect temperature compensation, depends on the initial sag. That is rather an advantage, because it enables us to adjust for zero temperature error. We use iron and copper in the tube in such proportions that the temperature error of the voltmeter is very small, but by a very small adjustment of the sag we can get a temperature error practically nought. That is a most interesting result, and one not foreshadowed in our original paper. During the past year we have again attacked the problem mathematically, taking it up where we left it in 1887; and by introducing the change of length of the fine platinum silver wire that occurs with change of stress, as well as the change of length that occurs with change of temperature, we have obtained formulæ that give results closely agreeing with those obtained experimentally by Mr. Bourne. Time does not allow of my going into the details of the mathematical reasoning, but the members will have an opportunity of criticising it when it appears in print. If the lamented founder of the Physical Society were still amongst us he would, I know, have chuckled at a result being obtained mathematically after it had been arrived at experimentally. But such a sequence shows, of course, not that mathematical conclusions are useless, but only how careful one ought to be that the mathematical data exactly represent the physical data.

By utilising the information taught us by these curves, we have succeeded in making hot-wire voltmeters of surprisingly large sensibility and small temperature error. In the one in front of you (Fig. 2), a rotation of the pointer through 360deg. is produced by 2·16 volts, and the scale, which is about 6in. in diameter, is subdivided to one hundredth of a volt. This particular instrument has been constructed for measuring the alternate P.D. at the terminals of the secondary coil of a Thomson-Houston electric welder, such as the one before you, and which experiment shows is under 2 volts, and which has to be measured when determining the efficiency of the welder. As, however, the absence of an alternate current prevents my showing you the welder in action, we will demonstrate the extreme sensibility of this voltmeter by using it to measure the E.M.F. of this accumulator, and the fall of the P.D. when the accumulator is sending a current. The E.M.F. of the accumulator the voltmeter shows is 2·07 volts. I now cause it to send 10 amperes as measured by this ordinary magnifying spring ammeter, and the P.D., as measured by the voltmeter, falls to 2·03 volts. The resistance of the accumulator is then

$$\frac{2·07 - 2·03}{10} \text{ or } 0·004 \text{ ohm.}$$

A result which this very sensitive voltmeter enables me to obtain almost instantaneously.

Fig. 3 shows a horizontal section of the instrument as at present constructed by the Acme Works. In the original instrument the pull of the magnifying spring, M, was counterbalanced by the pull of the platinum silver wire, W W, attached to the blocks, B B; but to save space both these pulls in the present instruments act on the same direction, and are counterbalanced by the flat spring, M. Hence, as the wire stretches, the magnifying spring, M, is stretched, and the pointer, P P, to which a number of fine hairs are attached to introduce damping without solid friction, rotates. This flat spring is not only introduced to enable the depth of the instrument to be diminished by twice the sag of the wire, but to enable us to introduce a particular form of fuse. In the ordinary Cardew instrument, with its two yards length of wire, the introduction of a short fuse, which will melt with a current too small to damage the instrument, does not seriously increase the resistance, or diminish the sensibility, but in our instrument, which contains only 8in. of wire, the introduction of such a fuse would diminish the sensibility; and if we attempt to diminish the length of the fuse wire in the same proportion as we have diminished the length of the working wire, the conduction of heat from the metallic blocks to which it is soldered is so great that the fuse does not melt. We therefore employ a fuse, F, of such a diameter that it would require a far larger current to melt it than would damage the instrument, but, in addition, we arrange a platinum tipped screw, D, so that when the wire, W W, is stretched by any prearranged percentage beyond the amount it stretches for the maximum safe P.D. the platinum tip, C, of the flat spring, S, comes into contact with the screw, D, and the working wire is short-circuited. The circuit is then temporarily completed through the lead, L, to the left, the flat spring, S, and the fuse, F, when the current increases and the fuse melts without damage to the instrument. With this device we find that the fuse may be thick, and therefore have but a small resistance compared with that of the working wire, and yet the sudden application of a P.D. five or six times as great as the maximum P.D. the voltmeter is intended to measure melts the fuse without damaging the working wire. For clearness, the fuse, the key, and the terminals, V, V, are shown detached from the instrument, but these are in reality in the base, as seen in Fig. 2.

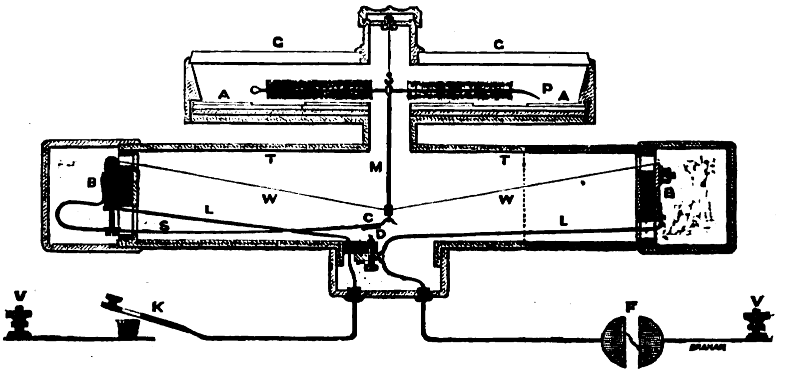

Fig. 3.—Horizontal Section of Hot-Wire Voltmeter.

CABLE REPAIRING UNDER DIFFICULTIES.

A neat bit of cable repairing under difficulties has just been achieved by Mr. Herbert L. Webb, at Cadiz, which we fancy will be found almost as interesting in its way as the finding of a deep-sea cable in 10,000 fathoms. Mr. Herbert Webb, with his friend Mr. Wilson, have constituted themselves into an electrical firm at Xerez, and do a good deal of work for the Spanish National Submarine Telegraph Company. The cable repaired is some few miles long, running to the opposite shore, in comparatively shallow water, of course, and had been broken by a steamer anchoring over it. The feat of repairing the break was accomplished by Mr. Webb with what accessories he could obtain, without cable-ship, and with his own hands. We give the account in his own words, taken from a letter home.

Digitized by Google

"I had a good deal of work over that cable job. On the Wednesday I went off at 6.30 a.m. to the dock, and they dispatched a pilot and some men to up anchor and move the ship that had the cable under her chain. I had been over the day before and had made a scratch repairing-ship of an iron raft, on which I had mounted an empty drum and a bow sheave, so as to be able to pick up and relay the piece of cable that had been dragged out seawards. We started off in the launch to look for the buoys, and found they had both sunk; so we grappled the Cadiz side and buoyed the end with a piece of cork, then made for the other side, and a tremendous squall came on with torrents of rain. We grappled the dock side again and buoyed the bight, but could do no work on account of the weather, and set out for the dock—drenched. The following day it was fine, and in the evening they notified me that the ship had been moved; so Friday morning early I was off to the dock. Found no steam was up in the launch, so put in time cleaning jointers' tools. At about nine we started off, towing my "cable-ship," which we moored to one of the iron buoys marking the line of the cable. Made for the cork buoy on the bight dock side and found it alongside a big steamer, which had one anchor down on each side of the cable, so we could not underrun. Dragged to seaward of the steamer, and grappled cable first shot. Underrun to end, which brought us quite close to our cork buoy on the other end, to my delight. We hauled on the piece that we had underrun, and coiled some of it on board. The launch then heaved up the other end and got it on board, made the dock end fast and heaved in on the other, gradually paying out on the dock side as the strain got heavy, and by this means picked up all the slack to the damaged part, where it had got twisted round the anchor that broke it. In this way we got the cable quite straight between the two mark buoys, and picked up all the slack we paid out at the time of laying, when we anchored to make the splice, and wasted some cable when we started getting the vessel on her proper course again. Then we put stoppers on both sides and cut out the damaged piece, and proceeded to joint and splice. My joint was not a very workmanlike affair and would have given a jointer a fit, but my hands were very dirty from helping the men (one can't very well be engineer-in-chief, cable hand, and jointer too), and there were various other difficulties, but I think it will keep out the water all right. The splice, too, was a difficult job, as the steel wires are very difficult to work with no tools and such a small space (the bows of the launch), but we made a good strong one, and lowered it over, and cut both the stoppers in true deep-sea fashion. We finished about one, so you see I made short work of it when once I had a fair chance. It was a lovely calm day. We set out for the dock and had breakfast, and spoke the office all right."

CORRESPONDENCE.

UNDERGROUND MAINS.

To the Editor of The Electrical Engineer.

Sir,—I have perused Mr. R. S. Erskine's letter in your last issue, and I regret to hear that he considers that his company is likely to suffer from there being two electric light stations in Kensington—viz., that of his company, known as the Kensington Court, and that of my company, known as the Kensington Central.

I take the opportunity of pointing out to you the following considerations, which bear upon this question:

1. The Vestry of Kensington has mapped out the parish of Kensington, and very carefully allocated certain districts to certain companies, so that it is impossible for my company to carry its mains into the district served by the Kensington Court Company, and it is equally impossible for the Kensington Court Company to brings its mains into the district alloted to us, so that I cannot see where confusion can arise.

2. In the event of customers in the Kensington Court district applying to us, it is clearly out of our power to supply them, and all we can do is to refer them to Mr. Erskine's company, and if he adopts the same procedure with customers applying to his company for light in our district, we can mutually work Kensington without trespassing upon one another's business.

3. Mr. Erskine points out that the Board of Trade have not yet sanctioned the license which is before them in favour of our company; and then he complains that we have up to the present time done no lighting in Kensington. No one is better aware than he is himself that until the Board of Trade's sanction is obtained no extensive lighting can be done, and that in the meantime we are limited to supplying the streets belonging to private persons where we have laid the mains without having to apply to the Board of Trade for its consent.

4. Mr. Erskine again draws attention to the fact that my company claims to have erected "*the first station which has been completed in the metropolis for the accomplishment of house-to-house electric lighting throughout an extended area by means of underground mains.*" My managing director, Mr. Robert Hammond, has pointed out to Mr. Erskine in *The Times* and elsewhere that Mr. Erskine's intimation that this company has done satisfactory work over a small area by means of underground mains is no refutation of the claim made by the House-to-House Electric Light Supply Company, Limited, that its station at Kensington is the first station completed in the metropolis designed to cope with electric lighting over an *extended area* by means of *underground mains.* The fact that Mr. Erskine's company has laid down a second station at Knightsbridge within a short distance of the first station, proves that from the first station his company is not able to cope with an extended area.

5. Mr. Erskine is well aware by what authority my company is supplying a portion of Kensington, and he is also well aware that the Vestry have sanctioned the application of my company to the Board of Trade for a provisional order covering a much more extended area than the one we are at present dealing with.

6. The station of my company has been called the Kensington Central Station, because it has been erected within the parish of Kensington, and is designed to supply a considerable portion of that parish with the electric light, and though we started by calling it the West Brompton Station we found that name did not sufficiently appeal to the householders of Kensington, to whom we were offering the light.

Yours, etc., H. St. John Winkworth.

House-to-House Electric Light Supply Company,
London, E.C., March 5, 1889.

PROPOSED HARROW LIGHTING.

We have received a long letter from Messrs. Taylor in reply to Mr. Crompton and Mr. Hayward. That portion of the letter dealing with Mr. Hayward is of very slight interest to our readers. The main drift of the argument is, that Mr. Hayward is wrong and Messrs. Taylor right. We cannot enter into details for appointments of committees, dates, etc., but record the fact that the difference exists. The following is the portion of the letter dealing with Mr. Crompton's remarks:

"Mr. Crompton's reply to our strictures is so courteous as almost to disarm criticism. Nevertheless, leaving aside all questions purely controversial, we may express our astonishment that so skilled an engineer as Mr. Crompton should propose to use the boilers of the disused Harrow Water Works to steam his engines. The boilers were in use some thirty years, and have lain idle, half full of scale, for the last three. The pressure gauges being only marked up to 100lb. show that they could only have been constructed for the low-pressure engines in use for pumping water. The engineers of the Westinghouse Company and of the National Company (as well as our own engineer) have inspected the boilers and have pronounced them unfit for use. Mr. Hayward, as a master in Harrow School, ought most assuredly to have informed Mr. Crompton that the Harrow School Laundry Company also surveyed these boilers some short time back, and were unable to use them owing to their wretched condition. We are at a loss to understand how Mr. Crompton expects to get into these boilers a head of steam sufficient to work compound engines economically, or even at all."

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places..................	4s. 10d.	...	9s. 8d.	..	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

DISTRIBUTION BY TRANSFORMERS.

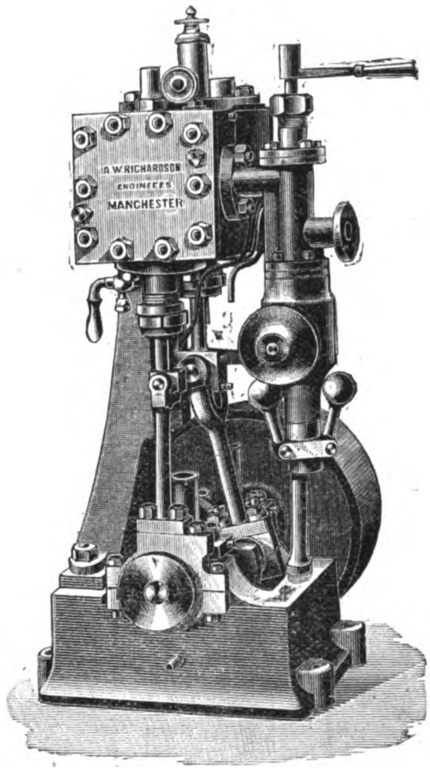
The result of the appeal concerning the Gaulard-Gibbs' patent, as will be seen from another column, is to invalidate that patent. It is unnecessary for us to discuss the terms or the reasons of the judges' decision; they are given fully in the judgment. We have, in consideration of the interests of our readers, to put them into possession of facts concerning what seems to be now the master patent, so that they may consider their ways and be wise. Let us, in the first place, pay a tribute of praise to the value of Gaulard-Gibbs' work. These gentlemen believed in themselves and in their hobby when most other people were sceptical. Their persistence gradually assisted to break down opposition, and compelled people to look into and acknowledge the merits of a system they were at first blush disposed to condemn. While, however, agreeing with the high value usually placed upon the work of Gaulard-Gibbs, we must not lose sight of the fact that a previous worker had shown as thorough a knowledge of the subject as could be shown at the time and under the then existing conditions, while another, almost contemporaneous with Gaulard-Gibbs, has been somewhat overlooked. The latter gentleman, Rankin Kennedy, of Glasgow, was, perhaps, the first to make a systematic examination of the capabilities of transformers. His writings in our contemporary, the *Electrical Review*, formed the first literary work upon the subject, and presented it in a manner "understanded of the people." He not only preached, but he practised, so that his conclusions carried great weight. But before all these came Paul Jablochkoff, who, in a patent dated May 2, 1877, described this method of distribution. It must be remembered that in 1877 the era of electrical progress had hardly commenced. Neither arc nor incandescent lighting were known, or if arc lighting was known to a few it was unknown in a commercial sense, and incandescent lighting "was not." The following year—viz., 1878, the year of the French International Exhibition—the Jablochkoff lamp illumined some of the streets of Paris, and the world began to realise that electric lighting was possible. The veterans who remember this time will recollect the battles-royal about "division"—how, on the one hand, a strong opposition urged the impossibility of divisibility, while, on the other hand, a few laughed at the mere notion of its being impossible. The incandescent lamp appeared on the scene, and settled all controversy as to divisibility. It is necessary to refer to the knowledge of the subject as it then was, to show how far in advance of the moment was Paul Jablochkoff. On the 23rd May, 1879, Sir Wm. Thomson, before the Select Committee on lighting by electricity, gave an answer to question 1783: "But the ordinary methods, of which we have heard, of dividing the light, do not seem to

Digitized by Google

be very much advanced, except in the case of the Jablochkoff candle?" "No, I believe that is the most advanced subdivision of the electric light which we yet have." This answer, as we say, determines the position of our knowledge prior to May, 1879. On referring to Jablochkoff's specification, p. 4, line 25, we read: "In this case the total system of distribution may consist of a central circuit, represented by the series of internal wires of the coils, from which branch out as many distinct conductors as there are bobbins in the circuit. Each lamp is therefore perfectly independent, and may be lit or extinguished separately. The distribution of electricity in a building to be illuminated is in this case similar to the distribution of gas. As a great number of induction-coils can be placed in the circuit, and as a number of lamps may be placed in the circuit of each coil, it will be seen that the electric light is thus capable of very great subdivision." The second claim of this specification reads: "The use of apparatus for the production of electric light, of induction-coils interposed in a primary circuit for generating separate and independent currents to be used for producing electric light in one or more lamps interposed in such secondary circuits, substantially as herein described." One sheet of drawings, containing three illustrations, accompanies this specification, and these are well worthy of attention. The rights of this patent at present centre in the United Electrical Engineering Company, and its value has been recognised by most of the best-known firms and companies, who have arranged to become licensees and to pay royalties. That the owners of the patent have been moderate in this question of royalties may be known from the fact that litigation has been avoided. The companies and firms who have hitherto not arranged for licenses will, no doubt, do so as soon as they become aware of the facts of the case and that users of transformers have been duly warned of the consequences of infringement. We are glad to hope that this business may be carried through without hint of litigation, as we feel assured there is no desire on the part of the owners of the patent to press unduly upon the profits obtained by business men in the due exercise of the work of the industry. If Gaulard and Gibbs were persistent, and their labours are to be appreciated, what about Paul Jablochkoff, who initiated the idea, and whose name is dropping into oblivion, because his "candle" showed the way and then passed away, whilst his other devices came to nothing in the hands of incapable men. Surely the facts we have mentioned testify once more to the necessity of inventors allying themselves to business men, and not to mountebanks and company promoters. Many good things die stillborn because the men who invent have no idea of business, and the men who undertake the business have only one object, "promotion money." Better remain satisfied with an immediate small return and a prospectively greater one, allied with real business, than be carried away with the glitter of both immediate and prospectively great gains. True business cannot afford to handicap itself with the payment of large sums, other than in perfecting the details of the invention and developing a purchasing *clientèle*.

THE "RICHARDSON" HIGH-SPEED ENGINE.

This engine, as illustrated, has been specially designed for driving dynamos direct or by belt or ropes, and it has been constructed with great care to run at high speeds with safety and economy, and without excessive wear. The crank is made of mild steel, carefully balanced. The cylinder and upright are cast in one piece. The cylinder



is steam jacketted, and is fitted with a liner, which, with the valve face, can be at any time renewed. The piston-rings and valve are of phosphor-bronze, all the bearings are extra long, and are made of either phosphor-bronze or best gunmetal. The crankshaft bearings are fitted in square, with wrought-iron caps, and the glands are specially constructed for lightening whilst running without the risk of jamming on the rods. The governor is of the high-speed class, and is very sensitive, and is also arranged so that it can be adjusted whilst running. An important point with regard to durability is that all the forged parts—bolts, studs, and nuts—are made of mild steel. All parts are made to template, and are interchangeable. The lubricating arrangement is made as perfect as possible, and is adapted for long and continuous running. In mills and other manufactories (also steamships) where the electric light is used, the most practical way of driving dynamos is direct by small high-speed engines, where there is boiler power to spare, as the light can be started before work commences, and can also be kept going at night until all hands are off the premises, and the light can also be kept running all night in case of repairs. These engines are very suitable for this purpose, taking up little room as the engine is fixed on same bedplate as dynamo. These engines will, no doubt, prove useful to electrical engineers where a good, reliable, and economical high-speed engine at a moderate

price is required. Engines of this class can be fitted with automatic expansion arrangement, if required, by the maker, Mr. A. W. Richardson, engineer, Stretford-road, Manchester.

SIEMENS' RECORDING APPARATUS FOR COMPACT MORSE WRITING.

The alphabet formed by the combination of two elementary signs, the "dot" and the "dash," which is used in Morse telegraph instruments of the recording type, is almost universally written in a single longitudinal line on the paper strip.

This method of writing, however, possesses the great disadvantage that the diameter of the writing-discs cannot be made very small, as it would not then be certain to dip into the ink contained in the trough. A disc of comparatively large diameter, although clean in its working, is unsuitable for producing a short and sharp sign on the paper strip, particularly when the strip is moving slowly, as the tangential contact between the writing-disc and the paper produces an unnecessarily long sign with a large disc, and hence the tendency to "tailing" is increased. It is for these reasons that the "dots" of the Morse alphabet can in general practice only be produced as short dashes, so that, in order to prevent misapprehension, the "dashes" require to be made longer than would be necessary if distinct dots could be produced. The writing is thus spread over far more paper than is desirable, causing not only a waste of paper, but making the reading more difficult.

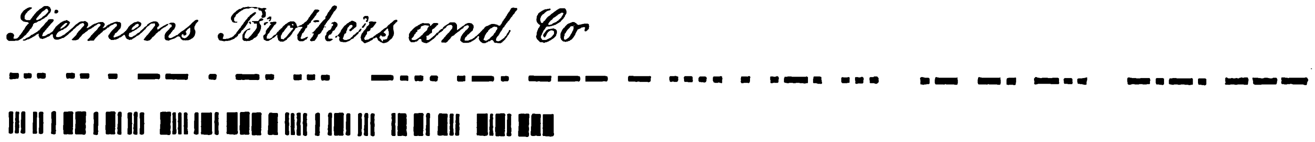


FIG. 1.

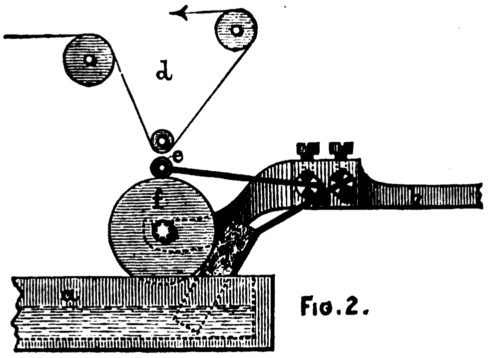

FIG. 2.

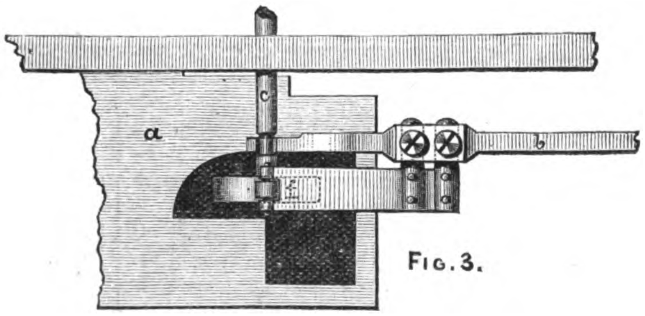

FIG. 3.

Various suggestions have from time to time been made with the object of remedying this defect; but, owing either to complication in the methods of transmission or of reception, none of these proposals have been adopted to any considerable extent.

The "compact writing" has been designed to meet the demand for improvements in the old system of Morse writing. Its elementary signs consist of lines at right angles to the edge of the paper strip and of equal width, but of different length (measured in the direction in which the paper travels), or short or thin line representing a "dot," and a longer or thicker line a "dash."

Fig. 1 illustrates the old and new system of writing, and shows the relative difference in space occupied by them. The length of paper used for the compact writing is about half that used for the old writing, while a more readable message is produced. The amount of paper strip to be stored away for possible future reference thus becomes considerably less—an administrative advantage not to be underrated when the present enormous increase in telegraphic communication is taken into account.

The inking arrangement, by which these compact signs are produced, consists, as shown in Figs. 2 and 3, of a marking-roller, *e*, of a small diameter, and of a width equal to that of the marks to be produced, mounted with its axis at right angles to the edge of the paper strip, and rotated by its frictional contact with the inking-disc, *f*. This inking-disc is carried on a spindle, *c*, resting in a bearing on the end of the armature lever, *b*, and is geared with the clockwork of the instrument by which it is revolved. It is of slightly greater width than the marking-roller, and has a finely-grooved periphery for more effectually taking up the ink. *a* is an ordinary ink-trough, and *g* is a pad of felt, which dips into the ink and presses against the inking-disc. The marking-roller, *e*, and the inking-pad, *g*, are both attached to the armature lever by flexible arms, and the amount of their pressure upon the inking-disc is regulated by small set-screws. *d* is the ordinary train of wheels over which the paper passes.

When the instrument is at work, the end of the armature lever carrying the marking-roller, inking-disc, and inking-pad, is moved upwards by the action of the electro-magnet, the marking-roller being thereby pressed against the paper, making a short or long mark according to the duration of contact. The inking-disc is rotated by the clockwork and, being supplied with ink from the pad, carries it to the marking-roller, which it at the same time causes to revolve. In this manner the marking-roller receives a very even, though ample, supply of ink, and a freshly-inked surface is constantly presented to the paper, by which means, combined with the very small diameter of the roller, short, sharp, and distinct marks are produced.

Experience has shown that any disinclination that may be felt by telegraph operators to change the method of writing the Morse code, is soon removed by the conviction that the new system offers considerable advantages to themselves, and that no difficulty whatever is experienced by the change from the old system to the new.

ON THE DESIGNING OF CONTINUOUS CURRENT DYNAMO MACHINES.*

BY PROF. JAMIESON, M.INST.C.E., F.R.S.E.

(Concluded from page 182).

Suppose we agree to a loss of about 10 per cent. of the total power in the dynamo, or say—

The electrical efficiency of the dynamo = 90 per cent.

$$\therefore 90 \text{ per cent.} : 100 \text{ per cent.} :: 6{,}400\ P_W : x.$$

$$\therefore \text{Total power} = x = 7{,}100\ P_W.$$

Let $$R_a = \frac{R_o}{20} = \frac{1 \cdot 55}{20} = \cdot 077\ \omega.$$

Let $$R_s = R_a \times 1{,}000 = \cdot 077 \times 1{,}000 = 77\ \omega.$$

Let $$R_m = 75\,\%\,R_a = \tfrac{3}{4} \times \cdot 077 = \cdot 058\ \omega.$$

Now, the external current = current in armature and field-magnet main coils less the current in shunt.

* Paper read before the Institution of Engineers and Shipbuilders of Glasgow. The illustrations referred to were given in our last issue.

Digitized by Google

Currents.—Or $C_e = C_a - C_s$.

But, $C_s = \frac{E_e}{R_s} = \frac{100\,v}{77\,\omega} = 1 \cdot 3\,a.$

$$\therefore 64\,a = C_a - 1 \cdot 3\,a.$$

$$C_a = 64 + 1 \cdot 3.$$

$$= 65 \cdot 3 \text{ amperes.}$$

Fall of potential in armature $= C_a \cdot R_a = 65 \cdot 3 \times 0 \cdot 77.$

$$= 5 \cdot 02 \text{ volts.}$$

Fall of potential in magnet main coils $= C_m \cdot R_m = 65 \cdot 3 \times \cdot 058.$

$$= 3 \cdot 78 \text{ volts.}$$

Total fall of potential in armature and magnet series coils

$$= C_a \text{ or } C_m (R_a + R_m).$$

$$= 65 \cdot 3\,(\cdot 077 + \cdot 058) = 8 \cdot 8\,v.$$

$$\therefore E_a = 8 \cdot 8 + E_e = 108 \cdot 8 \textit{ volts.}$$

Percentage losses of power.—

In armature $= C_a^2 \cdot R_a = 65 \cdot 3^2 \times \cdot 077.$

$$= 330 \text{ Pw.}$$

$$\therefore 7{,}100 \text{ Pw} : 330 \text{ Pw} :: 100 : x_a.$$

$$x_a = 4 \cdot 63 \text{ per cent.}$$

In shunt coils $= C_s^2 \cdot R_s = 1 \cdot 3_a^2 \times 77\omega.$

$$= 132 \text{ Pw.}$$

$$\therefore 7{,}100 \text{ Pw} : 132 \text{ Pw} :: 100 : x_s.$$

$$x_s = 1 \cdot 86 \text{ per cent.}$$

In main coils $= C_m^2 \cdot R_m = 65 \cdot 3^2 \times \cdot 058.$

$$= 248 \text{ Pw.}$$

$$\therefore 7{,}100 : 248 :: 100 : x_m.$$

$$x_m = 3 \cdot 5 \text{ per cent.}$$

Totalling the different percentage losses we have :

In armature...............	$x_a = 4 \cdot 63$ per cent.
In shunt coils	$x_s = 1 \cdot 86$,,
In main coils	$x_m = 3 \cdot 5$,,
	9·99 %. or say 10%.

Kapp Lines in Armature Core.—Now, before substituting the above data in Kapp's formula, we must agree upon the turns of wire in the armature at the agreed upon 1,000 revolutions per minute. Let there be 36 commutator bars or 36 sections of wire in armature, which has been found sufficient to give a current of practically uniform E.M.F. The number of turns of wire in each section of the armature depends upon whether we use double or single winding, and upon the current and the resistance of the armature wire. As we shall see further on, from our trial drawing and calculations, we can get in six turns of wire to each section.

$$\therefore T_{aw} = 36 \times 6 = 216 \text{ turns of armature wire.}$$

Let $N_{ar} = 1{,}000$ revolutions per minute.

Now $E_a = \mathbf{K}_L \times T_{aw} \times N_{ar} \times 10^{-6}.$

$$\therefore \mathbf{K}_{La} = \frac{E_a}{T_{aw} \times N_{ar} \times 10^{-6}}.$$

$$= \frac{108 \cdot 8\,v}{216 \times 1{,}000 \times 10^{-6}} = 503 \cdot 7$$

say = 500 Kapp lines in *armature core.*

In order to obtain a certain number of Kapp lines or magnetic induction in an armature core, it is necessary to give a greater magnetic intensity to the field-magnet core or cores, owing to the unavoidable leakage of magnetic lines which do not pass through the armature core.

Dimensions of Magnet Core.—In ordinary practice it is usual to assume that only about 80 per cent. of the field-magnet lines pass through the armature core.

Therefore, the Kapp lines in *field-magnet* are

80 per cent. : 100 per cent. :: 500 : $x = 625$.

We must now ascertain the dimensions of the field-magnet core to carry these 625 Kapp lines. Suppose we consider the case of field-magnets to be cast iron throughout (poles and core).

A safe working density is 9 Kapp lines per square inch.

$$\therefore \mathbf{S}_m = \frac{625}{9} = 69 \cdot 4 \text{ square inches.}$$

$$= 9 \cdot 4 \text{ inches diameter (if round).}$$

In practice it is found that a dynamo magnet bobbin should be in length about $1\frac{1}{4}$ times its diameter to give the necessary space for winding or ampere-turns.

$$\therefore 9 \cdot 4 \times 1 \cdot 25 = 11 \cdot 75 \text{ inches long.}$$

Dimensions of Armature Core.—It has been found advisable, in designing the dimensions of the armature core of a dynamo having a field-magnet of the form we are now considering, to make the diameter of its core slightly larger, and its length slightly less, than the diameter of the field-magnet core.

Therefore, calling the diameter of the Gramme armature core 10in., its length 9in., and allowing a density of 20 Kapp lines per square inch of core section, since it is made of the best permeable wrought iron, we have

$$\frac{500}{20} = 25 \text{ square inches total cross-section of armature.}$$

$$\therefore \mathbf{S}_a = 25 \text{ square inches.}$$

Allowing 20 per cent. of total space for insulation between *laminated plates* in armature core, we have

80 per cent. : 100 per cent. :: 25 : $x = 31 \cdot 5$ square inches.

$$\therefore \frac{31 \cdot 5}{2} = 15 \cdot 75 \text{ square inches in each half.}$$

$$\therefore \frac{15 \cdot 75}{9''} = 1 \cdot 75\text{in.} = \text{radial depth of core.}$$

Magnetic Resistance of Field-Magnet.—Now, drawing armature and field-magnets to scale (as per Fig. 4) and allowing $2\frac{1}{4}$in. for depth of winding on field-magnet bobbin and clearance for armature, we find the mean length of field-magnet core, $\mathbf{L}_m = 44$in., and remembering that in a formula for the magnetic resistance of this part of the circuit we have to use a coefficient of 3 instead of 2, seeing that the core is of cast iron, we have

$$\mathbf{R}_m = 3\,\frac{\mathbf{L}_m}{\mathbf{S}_m}.$$

$$= 3\,\frac{44}{6 \cdot 94} = 1 \cdot 9.$$

Magnetic Resistance of Air Space.—With *two* layers of insulated conductors having a cross section (▭) of ·08in. deep, by ·2in. broad (including covering), we find the total depth of air space on one side between pole-pieces and armature core (allowing ·14in. mechanical clearance), equal ·3 of an inch.

Consequently, $2\,\mathbf{L}_{as} = 2 \times \cdot 3 = \cdot 6$in.

The bore of pole-pieces will be = diameter of armature core + $2\,\mathbf{L}_{as}$

= 10in. + ·6in. = 10·6in.

It is good practice to allow the corners of pole-pieces to form an angle of 30deg. with centre of armature. The angle embraced by each pole-piece will therefore be 180deg. – 30deg. = 150deg., which gives us a circumferential length of, say, 14in. for each pole. And since our armature core is 9in. long, and it is unusual to make the pole-pieces broader than this length, we have

$$\mathbf{S}_{as} = 14\text{in.} \times 9\text{in.} = 126 \text{ square inches.}$$

Hence— $\mathbf{R}_{as} = 1{,}800\,\frac{2\,\mathbf{L}_{as}}{\mathbf{S}_{as}},$

$$= 1{,}800\,\frac{2 \times \cdot 3}{126} = 8 \cdot 5.$$

Magnetic Resistance of Armature.—Referring to scale or full-size section, we find by measurement that $\mathbf{L}_a = 15$in. We have already determined $\mathbf{S}_a$ to be 25 square inches.

Consequently— $\mathbf{R}_a = \frac{\mathbf{L}_a}{\mathbf{S}_a},$

$$= \frac{15}{25} = \cdot 6.$$

$$\therefore \mathbf{R}_m + \mathbf{R}_{as} + \mathbf{R}_a = 1 \cdot 9 + 8 \cdot 5 + \cdot 6$$

= 11 Kapp units of magnetic resistance.

Ampere-Turns.—From formula for *cast* iron, under heading VIII.

$$\mathbf{K}_L = \frac{A \times T_{fw}}{\mathbf{R}_m + \mathbf{R}_{as} + \mathbf{R}_a} = 625 \text{ (gross Kapp lines)}$$

Digitized by Google

Therefore $A \times T_{mw} = K_L (R_m + R_{as} + R_a)$,
$= 625 \times 11$,
$= 6,875$ total ampere-turns in shunt and main field magnet coils.

Proportioning of Ampere-Turns between Shunt and Main Coils.—The total ampere-turns have now to be divided in proper proportion between the series coils and the shunt-coils of the field-magnet windings.

In order to do this, so as to give the desired form of characteristic curve, we must have recourse to actual experiment. The following method is carried out by Messrs. M'Whirter, Ferguson, and Co., Faraday Works, Govan :

1. A workshop bobbin or experimental coil, with a known number of turns of wire, is kept for every size of dynamo machine made. This bobbin is put on to the magnet core in circuit with an ampere-meter, and is separately excited by another dynamo or storage cells. The dynamo to be wound is run at the normal speed with the external circuit, R_e, equal to that of shunt—viz., 77 ω—and with the voltmeter placed between the terminals. The exciting current through the experimental bobbin is now gradually increased until the required number of volts is observed on the voltmeter—*e.g.*, suppose the experimental bobbin to have 500 turns, and the ampere-meter reads 8·25 amperes, when the normal voltage of 100 volts is reached, then the ampere-turns of shunt wire

$$A \times T_{sw} = 500 \times 8{\cdot}25 = 4,125 \text{ ampere-turns.}$$

2. Connect up the armature of the dynamo being constructed to a resistance equal to the joint resistance of the shunt, and the normal lamp circuit through an ampere-meter, and run the dynamo at the normal speed. Now increase the exciting current in the experimental bobbin until the normal voltage of 100 volts and normal armature current of 65·3 amperes are both obtained. At the same time observe the exciting current.

But the total required ampere-turns = 6,875, and from experiment (1) we found that 4,125 ampere-turns produced the requisite E.M.F.

∴ 6,875 − 4,125 = 2,750 ampere-turns left for series-coils.

3. The normal current at full load required to pass through the series-coil was found to be 65·3 amperes.

Consequently the number of turns required in the series-coils

$$= \frac{2,750}{65{\cdot}3} = 42 \text{ (about).}$$

4. From experiment (1), we found that 4,125 ampere-turns gave us the required excitation to produce the normal E.M.F., and from our former calculation we found that the current in shunt,

$$C_s = 1{\cdot}3 \text{ amperes.}$$

$$\therefore \frac{4,125}{1{\cdot}3} = 3,173 \text{ turns.}$$

But the series-coils are also carrying the 1·3 amperes required for the shunt when dynamo free.

∴ 3,173 − (42 turns × 1·3 *a*) = 3,173 − 54 = 3,119 turns on shunt-coils.

5. All we now have to do is to so proportion the size of our series and shunt coil conductors that they shall carry the necessary currents required in each case at the rate of not exceeding 1,000 amperes per square inch. For armatures this may be and is in practice increased to even 3,000 amperes per square inch without undue overheating, owing to the cooling effect of the air carrying off the heat generated in the revolving armature. Mere radiation only acts on the field-magnet coils, therefore the sectional area is of necessity much greater.

Example II.—Now take the case of a Rankin-Kennedy short shunt compound dynamo of the form shown by Fig. 1. The particular dynamo in question was tested by the writer after completion, with the following results :

Resistance of armature, warm,	R_a	= ·04 ohm.
Resistance of magnet shunt, warm,	R_s	= 20 ohms.
Resistance of magnet main coil, warm,	R_m	= ·03 ohm.
Current in working circuit,	C_e	= 108·5 amperes
Current in shunt-magnet coils,	C_s	= 5 amperes.
Difference of potential at dynamo terminals,	E_e	= 100 volts.
Difference of potential at brushes,	E_b	= 103 volts.
E.M.F. generated in armature,	E_a	= 108 volts.
Turns of armature wire,	T_{aw}	= 180.
Number of armature revolutions per minute,	N_{ar}	= 620.

Electrical Efficiencies.

External electrical power, or "output," available for electric lighting, etc.,

$= C_e \times E_e = 108{\cdot}5_a \times 100_v = 10,850$ watts = 88·7%

Power absorbed by armature,

$= C_a^2 \times R_a = (113{\cdot}5)_a^2 \times {\cdot}04\omega =$ 515 watts = 4·2%

Power absorbed by shunt magnet-coils,

$= C_s \times E_s = 5_a \times 103_v =$ 515 watts = 4·2%

Power absorbed by main magnet-coils,

$= C_m^2 \times R_m = (108{\cdot}5)_a^2 \times {\cdot}03\omega =$ 353 watts = 2·9%

Total electrical power,

$(C_e \times E_e) + (C_a^2 \times R_a) + (C_s \times E_s) + (C_m^2 \times R_m) = 12,233$ watts.

The only difference between this dynamo and our last example being that the magnet core was made of the best hammered scrap iron instead of cast iron, and consequently the permeability is greater. The constants to be used in the formula are therefore less, and we have to substitute 2 for 3, and 1,500 for 1,800 as found by experiment.

From the measured dimensions of the dynamo we found :

$L_m = 38$ inches.	$S_m = 98$ square inches.
$L_{as} = 0{\cdot}45$ "	$S_{as} = 195$ "
$L_a = 15$ "	$S_a = 46$ "

$$\therefore R_m = 2\frac{L_m}{S_m} = 2\frac{38}{98} = {\cdot}76$$

$$R_{as} = 1,500\frac{2L_{as}}{S_{as}} = 1,500\frac{2 \times {\cdot}45}{195} = 6{\cdot}9$$

$$R_a = \frac{L_a}{S_a} = \frac{15}{46} = {\cdot}33$$

Total magnetic resistance = 7·99

Now by substituting in our former formula the actual values obtained for the E.M.F. in the armature, turns of armature wire, and revolutions per minute, we get the magnetic flux in Kapp lines flowing through the armature. Or,

$$K_{La} = \frac{E_a}{T_{aw} \times N_{ar} \times 10^{-6}}$$

$$= \frac{108}{180 \times 620 \times 10^{-}}$$

= 968 *lines of magnetisation through armature, or at the rate of* 21 *Kapp lines per square inch.*

But in dynamos of this class it has been found that the number of magnetic lines passing through the armature are only 80 per cent. of the total magnetisation in the field-magnets. Consequently,

$$80\% : 100\% :: 968 : x$$

∴ $x = 1,210$ *Kapp lines through the magnet cores, or at the rate of* 12·3 *Kapp lines per square inch.*

From our former formula,

$$K_L = \frac{A \times T_{mw}}{R_m + R_{as} + R_a}$$

$$1,210 = \frac{A \times T_{mw}}{7{\cdot}99}$$

= 9,668 ampere-turns on the field-magnets.

The actual ampere-turns were 9,800, or the calculation is only about 1 per cent. less than the *actual* amount required to satisfy the requirements of the installation.

Example III.—Take the case of a Faraday compound dynamo, also tested by the writer, supplied by Messrs. M'Whirter, Ferguson and Co., Govan, to the Blair Lodge School. Where (see Fig. 3)

R_a = ·0315 ω	E_e = 100 v.
R_s = 31·0 ω	E_a = 107·6 v.
R_m = 0·012 ω	E_b = 102 v.
C_e = 130·0 *a*	T_{aw} = 240 (48 commutator bars)
C_s = 3·55*a*	N_{ar} = 800

Digitized by Google

This dynamo being of the double horseshoe magnet type, and the cores being of the best Swedish iron, with large cast-iron yokes, we use a constant two for wrought-iron cores, and 1,440 for specific resistance of copper and air space due to wrought cores and pole-pieces.

From the actual dimensions of the dynamo we found:

$\mathbf{L}_m = 32{\cdot}0$in. $\quad \mathbf{S}_m = 33$ square in. (only 1 magnet core).
$\mathbf{L}_{as} = 0{\cdot}5$,, $\quad \mathbf{S}_{as} = 54$,, ($\frac{1}{2}$ hair-space surface).
$\mathbf{L}_a = 12{\cdot}0$,, $\quad \mathbf{S}_a = 15{\cdot}6$,, ($\frac{1}{2}$ section of armature).

$$\therefore \mathbf{R}_m = 2\frac{\mathbf{L}_m}{\mathbf{S}_m} = 2\frac{32}{33} = 1{\cdot}94$$

$$\mathbf{R}_{as} = 1{,}440\frac{2\mathbf{L}_{as}}{\mathbf{S}_{as}} = 1{,}440\frac{2 \times {\cdot}5}{54} = 26{\cdot}6$$

$$\mathbf{R}_a = {}^*2\frac{\mathbf{L}_a}{\mathbf{S}_a} = 2\frac{12}{15{\cdot}6} = 1{\cdot}54$$

Magnetic resistance of half-dynamo field = 30·08

Now,

$$\mathbf{K}_{La} = \frac{\mathrm{E}_a}{\mathrm{T}_{aw} \times \mathbf{N}_{ar} \times 10^{-6}}$$

$$= \frac{107{\cdot}6}{240 \times 800 \times 10^{-6}}$$

= 530 *lines of magnetisation through armature, or at the rate of*

$\frac{530}{15{\cdot}6 \times 2} = 17$ *Kapp lines per square inch of armature section.*

Allowing, as before, that only 80 per cent. of the total magnetisation passes through the armature, we have

$$80\% : 100\% :: 530 : x.$$

$x = 662$ Kapp lines through both the magnet cores, or 331 lines through each half, which is at the rate of 10 Kapp lines per square inch of magnet core section.

$$\therefore \mathbf{K}_L = \frac{\mathrm{A} \times \mathrm{T}_{mw}}{\mathbf{R}_m + \mathbf{R}_{as} + \mathbf{R}_a}$$

$$\text{Or } \mathrm{A} \times \mathrm{T}_{mw} = \mathbf{K}_L\,(\mathbf{R}_m + \mathbf{R}_{as} + \mathbf{R}_a)$$

$$\therefore \mathrm{A} \times \mathrm{T}_{mw} = 331 \times 2 \times 30{\cdot}08 = 19{,}913.$$

The actual ampere-turns were 20,850, and the dynamo having a rising characteristic of 3 per cent., the calculation is only about 1·7 per cent. less than actually found by experiment.

SOME ELECTRIC LIGHTING CENTRAL STATIONS IN EUROPE AND THEIR LESSONS.†

BY PROF. GEORGE FORBES, F.R.SS. (L. AND E.), MEMBER.

PART I.

Before commencing the subject of this paper, I think it may be well if I give you some idea of the reasons why I have brought the subject to your notice. You are aware that great strides are about to be made at the present time in electric lighting in this country, specially by means of the Gaulard and Gibbs system with the converters put in parallel. To complete the practical details of such a system involves a large amount of experiment, and whether low-pressure or high-pressure work is in question, I have frequently maintained that a great deal of experience has still to be bought and time to be wasted. It has appeared to me that we can only hope to ensure the best success of electric lighting schemes now in hand if we bury our pride a little, and try to obtain the experience of foreign countries without paying for it or wasting time over it, as they have done. Some irresponsible persons have considered that I am much to blame for thus advocating the discussion, and consequent approval or disapproval, of systems which have been developed in foreign countries. I do not say that we are not even now capable of doing much better work than these countries, as we have done with steam, and I am certain that we shall do so in the course of time; but I do say that we are wanting in the experience, and I see all over the country work being done where the rules of experience have often been set at defiance; and my object in introducing this subject is chiefly for the second part of the title of the paper—namely, a discussion of the lessons which can be derived from a study of the work which has been done abroad. The object of this paper, then, is to raise a discussion on the details of central station lighting and electrical distribution, and to enter a protest against defective systems, which, without some such discussion, I feel sure will be as plentiful in the near future with us as they have been up to the present time.

Of course I am aware that many of my hearers have appreciated these points, and have, like me, tried to learn from those who have had most experience; and I know that they will pardon me for drawing attention to work that they have already examined, since they know as well as I do the need we have for such discussion.

I believe that my object can be best attained by proceeding, first, to describe the principal central stations in Europe which I have lately visited, pointing out specially the features in which they differ from the practice in this country so far as hitherto developed; and then to discuss the details, with a view of deriving the most profitable lessons from them as to what to adopt and what to avoid. I will deal only with what I believe to be the three most important central stations in Europe—namely, Berlin, Rome, and Milan. I have already partially dealt with America elsewhere.*

Berlin is supplied on the low-tension direct-current system, as originally developed by Edison, except the arc lights, which are on a high-pressure direct-current circuit.

Rome is supplied altogether, both for arcs and incandescent, on the Gaulard and Gibbs system, with converters arranged in parallel.

Milan is worked by Thomson-Houston apparatus for arcs, and by both low-pressure currents and high-pressure alternating currents for incandescent lamps.

At all the European stations which I have visited I received the same cordial welcome which I have always had in America, and the same desire that I should thoroughly inspect every part of the works. The stations have literally been placed at my disposal to watch the action of the machinery, and to see what attention is required for its management. I have been allowed to interchange dynamos at will, and generally to learn all that was possible. I must especially record my thanks to Signor Pouchain, Prof. Mengarini, Signor Trenza, Prof. Colombo, Mr. Lieb, Herr Rathenau, and Herr Datterer, for the willingness with which they imparted to me so much information in the details of their working, and to Mr. Zipernowski and Messrs. Ganz and Co. for much valuable information.

Berlin.

The Berlin mains are at present, I believe, supplying a larger number of lights than any other connected system of mains in Europe. They supply 36,000 lamps of 16 c.p., and 144 arc lamps of 15 amperes. The conductors are all laid underground. A map is shown giving the position of mains already laid down and those in progress of construction. There are three central stations at work, and two more of improved type are in process of construction.

The existing stations are: 1. Markgrafen Strasse. 2. Meuer Strasse. 3. Friedrich Strasse.

Those about to be added are: 4. Spandauer Strasse. 5. Schiffbauer Damm.

The first is the most important; the third is quite unimportant. Here the boilers are by Steinmiller, and anthracite coal is used to prevent nuisance from smoke. The foundations are of concrete, in iron boxes, built up with brickwork and cement. There are six engines, of 160 h.p. each, each driving old-fashioned Edison six-legged dynamos. There are also four engines, of 400 h.p. each, each driving a new type of dynamo direct at 80 revolutions per minute. These are compound tandem Corliss condensing-engines, by Van den Kirchove, of Ghent, who is one of the few foreign makers of engines who can compete with this country. The attached dynamos are by Siemens and Halske. The Electric Company of Berlin are also making a machine somewhat similar. A diagram is shown of this dynamo and of the engine combined, the height of which is 23ft. These continuous-current dynamos have never been built in this country, and are worthy of some notice. They may be described as multipolar Gramme machines, the poles being radial, and the ring armature external to the poles.

There are ten poles on each machine. The armature is 3 metres in diameter; the commutator is 1½ metres in diameter. There are 10 brush-holders. Each pair of poles, and the corresponding part of the armature, with the corresponding pair of brush-holders, constitute a section which is virtually one machine. All these sections are joined in parallel. The field-magnets are not seen in the drawing, being inside the armature. Two handles are provided, one of which adjusts all the brushes at the same time; the other puts them on all together. Each brush-holder carries four brushes. Another drawing is shown of a similar dynamo being made by the Berliner Elektricitäts-Werke, in which the radial poles are external to the armature. I believe that this type of multipolar machine is a good design where the object is to get a large output with a slow speed. I hold working drawings in my hand of a similar design prepared by myself in 1881, but it was never executed. The number of bars of the commutator and the number of parts generally make it expensive to construct.

* 2 is here on account of the double field, or the magnetic lines or circuit entering from each side.

† Paper read before the Institution of Electrical Engineers, Feb. 28.

At this station the boilers are fed automatically by means of a hydraulic accumulator. The water for condensing is drawn from 15 artesian wells which have been sunk for this purpose. Steam is used at a pressure of 115lb., and it is claimed that 15·5lb. of steam only are required per electrical horse-power. This is probably the most economical production of electricity for central station work in the world, and the engines and dynamos, though expensive, must certainly have a very low depreciation. The maximum work which this station can do is to generate a current for 26,000 lamps of 16 c.p. It is found that the maximum number of lamps in use at any one time is about 66 per cent. of the total number of lamps.

The thing which strikes one most in this station is the enormous mass of copper. The conductors inside this station consist of eight strips of copper, 6in. wide and $\frac{1}{3}$in. thick. These are laid into the room for cable terminals. These strips, before entering this room, are interrupted by a gap, and a junction is made by punching seven similar strips, about 18in. long, between the strips and the interrupted ends, the seven strips being placed between. Thus, in case of any serious accident, the whole of the mains can, by one turn of a screw, be disconnected from the dynamos, the interlapping pieces all dropping out. The only exception is in the case of theatres, where, to prevent panic, a separate connection is made with the dynamos. In the cable terminal room the positive and negative mains run horizontally, and vertical rods come down to the different cables. There are 84 of these cables, forming 42 pairs of feeders supplying the network of mains with current on the two-wire system. These cables are generally of large size, being frequently 3in. in diameter complete. They consist of stranded cables covered with jute prepared with bituminous compound, enclosed in lead, then covered with tape and preservative compound, and finally armour-plated with two crossed spirals of iron ribbon. The system of feeders and mains is one of the features to which I wish to direct the special attention of English engineers, since the principle has been adopted of trying to produce as small a variation of pressure in the mains as possible. This is accomplished by having a large number of converters. The cost of the underground cables has hitherto amounted to about £90,000, half of this being spent in mains and half in feeders. The greatest variation of pressure allowed in the mains is 1½ per cent. The loss of pressure in the feeders during periods of maximum supply is 15 volts.

The next point which I wish to draw special attention to in connection with the Berlin central station work is the type of cable which I have now described. This cable succeeded very well for three years, but lately they have been giving way very generally. The lead gets eaten into and water percolates to the copper, which is then destroyed. At first it was supposed that the deterioration came from the cable being pierced by the borers used by the gas people, but it was found that the same fault is produced even in iron pipes which have remained uninjured. It is supposed that the deterioration of the lead may be due in some way to its forming a galvanic element with the iron sheathing. Whatever the cause may be, the fact seems to be established that such cable will not stand underground electric light work for more than about three years. These cables generally run under the footways without any casing, and are connected by circular junction-boxes to the houses, powerful clamps and no soldering being used for the contacts. All the dynamos feed direct on to the mains in parallel. One feeder alone, serving the mains close to the station, has a resistance in circuit in the station to equalise its loss of pressure to the others.

A few detached facts strike me as being worth noting. Each 16-c.p. lamp uses 50 to 55 watts. The charges for electric supply are 6s. per lamp per annum, and 9·6d. per Board of Trade unit. The Aron meter is universally employed. The price of gas in Berlin is 4s. 10d. per 1,000 cubic feet. The distances from central stations to lamps extend to 1,000 or 1,200 yards; 100 kilometres of cable have been laid on the two-wire system. Each of the large machines can supply 3,000 to 3,500 lamps of 16 c.p. The largest cable is 1½ square inches of copper in section.

I spent a long time in this station, and had machines taken off and put on—an operation which occupied two or three minutes. I took careful note of the amount of skilled attention which was required, and saw that it was considerable. A man of high training, accustomed to the use of scientific instruments, is always in attendance and looking after the amperes and volts from the different machines and pilot wires, and recording the measurements. It struck me that the working of this station was thoroughly German—certainly not American—but it was most methodical and very effective. One of the most interesting parts of this central station is the switchboard, with the special means for introducing a fresh dynamo in parallel, or cutting it out. This also is a point to which sufficient attention has not generally been given in England. In all foreign stations that I have ever seen, when a current of over 100 amperes is switched in or out, it is found necessary to make use of an auxiliary load in the form of resistances, a bank of lamps being generally employed as being the cheapest resistance available. When a new dynamo is going to be introduced in parallel, it is first worked on an artificial load, and the exciting current regulated until the volts and amperes agree with those of the other dynamos with which it is to be put in parallel. As soon as this equilibrium is attained, the mains are switched into connection with the new dynamo and its load. After that the load is taken off. This prevents the possibility of the dynamo thus introduced being caused to run as a motor in the wrong direction by the current from the other dynamos, and prevents too violent a sparking at its brushes. The switchboard at this central station for the four large dynamos, with the accompanying artificial load or resistance, and with its ammeters and voltmeters, is very perfect. Facing the operator, the switchboard is in four sections for the four dynamos. Each dynamo has three massive double-pole switches—one for the dynamo, one for the artificial resistance, and one for the mains. Plugs can be inserted for varying the resistance on the artificial load. The ammeter is placed above these switches for each machine, and a voltmeter can be attached to any one of them, as required. A photograph of this switchboard is reproduced.

The second station is in the Mauer Strasse. This station helps to feed the mains for incandescent lamps. It also supplies arc lights arranged in 12 circuits all arranged in parallel, each circuit having 12 arc lamps of 14 to 15 amperes. Here three Siemens machines of the old type are driven by a countershaft. Three Siemens and Halske new-type multipolar machines are also at work, and four Edison machines and six multipolar machines of low tension. Eleven thousand lamps of 16 c.p. can be supplied besides the arcs. Sixty-eight feeders, or 34 pairs, start from this station.

The Friedrich Strasse station is small, and was the commencement of the present system. Here four six-legged old-type Edison machines, each of 75 h.p., are driven by Armington-Sims engines, and feed the general system of mains. Fifty-two men are employed on the three stations in eight-hour shifts. The Berliner Elektricitäts-Werke paid last year a dividend of 5 per cent.; the Algemeine Elektricitäte Gesellschaft, which does the central station work, paid last year 7½ per cent. In special districts 800 or 900 lamp-hours per annum are used; in residences only 400 to 500 lamp-hours per annum. Load diagrams showing the current used at different hours of the day in each month, and the proportionate cost from different causes, fixed and variable, have already been published, but are here reproduced.

Milan.

The central station in Milan is not of the highest importance, so far as we can learn anything from it, except on one important point. The principal streets throughout the whole town are lighted by Thomson-Houston arc lights to the number of 350. This lighting gives us some idea of the manner in which this metropolis will soon be lighted, and anyone who sees it and realises that this clear, white, brilliant illumination may be made to brighten our wider thoroughfares, and to penetrate our darkest slums, will realise that when London is as far advanced in adapting these possibilities of civilisation as Milan is, we shall lead healthier, happier, and purer lives, and our streets will be less notorious throughout the world as the hotbeds of immorality and midnight assassination.

I will briefly refer to the points which struck me as being most worthy of notice. The station has 14,000 incandescent lamps of 16 c.p. The maximum load is 60 per cent. of the number of lights installed. At this station it has been found quite practicable to use Siemens ratchet arc lamps of only 4½ amperes, the upper carbon being 12mm. diameter and 200mm. long, the lower one 7mm. diameter and 200mm. long, lasting 7½ to 8 hours. For long duration, larger carbons are used up to 15 hours. This is the first station where I have seen an arc lamp of so low a current in use. A certain resistance is put in series with the lamp, and two lamps are put in series on the mains feeding the Edison lamps.

The La Scala Theatre has 2,800 glow lamps of 16 candles and 30 arcs on the same mains. Edison meters are used, and have given great satisfaction. The price is fixed on a sliding scale, varying from 7d. to 1s. per Board of Trade unit. Gas now costs about 6s. 9d. the 1,000ft. Before the electric light was introduced it was 10s. 6d. the 1,000ft.

Two of the theatres are supplied by two Zipernowski machines, each of 40 amperes and 2,000 volts. For these circuits Siemens concentric cables, of which a specimen is exhibited here, are used, the section being 28 square millimetres. Four Thomson-Houston machines are supplying 35 arc lights each, and four more are supplying 30. Half of these are single and half double carbon lamps, the single ones being put out at midnight. I should mention that the coal used costs 27s. 6d. per ton, but labour is cheap.

Ten Babcock and Wilcox boilers supply the steam. The engines are all non-condensing. The low-pressure system is a two-wire system. Twenty-eight cables, or fourteen pair of feeders, supply current to the mains. No pilot wires are used, but a man reads the ampere-meter and sets the volts by a table. There are ten Edison machines of what is known as the Jumbo

Digitized by Google

type feeding mains on the two-wire system. They were originally supplied each with a separate regulator for adjusting the exciting current, but connecting gear has now been introduced, which works them all simultaneously. A fan is provided for driving air through holes in the poles of the field-magnets. The whole of the low-tension system is antiquated, and we have little to learn from it except what to avoid. I found the arrangements for switching dynamos in and out worked very well. An artificial load of lamps is used at one part of the room, a main going thence past each dynamo. Thus two men are required to put in a new dynamo. It is first put on to the lamps, the machine being excited to the same extent as the other ones. The load of lamps is changed until the volts are the same as on the working circuit. A signal is then given, and the dynamo with its load is switched on to the working mains. The load of lamps is then removed. This is simpler that at Berlin, owing to the fact that the exciting current is known beforehand, but less simple owing to the dynamo switches being distant from the lamps and voltmeters. Ten machines work thus in parallel without trouble, which is a very good performance.

At Milan, the average cost for wiring houses is only £1 per lamp. Wages are one-fifth of the total working expenses, coal is one-half, lamp renewals (undertaken by the company) is 7 per cent. The capital is £120,000, of which £24,000 has been spent in mains. The company has paid a dividend for several years. It is steadily increasing, and was 4 per cent. last year. There is a large reserve fund.

Plans are exhibited, one showing the positions of the arc lamps, and also the alternate-current circuits, and the other showing the low-pressure mains and feeders, with the junction boxes and distributing boxes. Another drawing shows the station in section, with the engines and dynamos on the ground floor, and the boilers on the first floor. Another shows the plan of the engine and dynamo room.

(To be continued.)

LEGAL INTELLIGENCE.

IN RE GAULARD AND GIBBS' PATENT.

This was an appeal, before Lords Justices Cotton, Lindley, and Lopes, by Messrs. Gaulard and Gibbs and the National Company for the Distribution of Electricity by Secondary Generators, Limited, against the revocation by Mr. Justice Kekewich, on the application of Sebastian Ziani de Ferranti, of letters patent (No. 4,362 of 1882) which were granted to Gaulard and Gibbs in respect of "a new system of distributing electricity for the production of light and power." Shortly stated, the appellants claim to have been the first to solve, by their patent of 1882, the problem which had for some years greatly exercised the minds of electricians and men of science, of devising a system of electric distribution that would enable a single dynamo machine to supply electricity at a high tension and feed a succession of lamps at local stations, which might be turned off and on independently of one another, by a long main wire, so small as to avoid the great expense of a wire of large diameter. At the same time, the electricity is made practically serviceable, and the danger that would arise if electricity of a high tension were used in houses and buildings is obviated in practice, by constructing the local secondary generators, or induction-coils, so that the induced electricity shall be of a sufficiently low tension. It was admitted that the three elements—an alternating dynamo machine for supplying an electric current at high tension, a small conducting-wire, and induction coils, or secondary generators—were not new in themselves; but it was claimed that the appellants had been the first so to combine and select these elements as successfully to overcome the difficulties of distributing electric light over a large area from a central station —*e.g.*, at the different stations of the Metropolitan Railway (a circuit of some 15 miles) from the Edgware-road as a central station of installation. The respondent, Sebastian Ziani de Ferranti, was an electrician, and in December, 1885, he had obtained provisional protection (No. 15,141, 1885) for an invention in respect of "improvements in electrical conductors," and since filed a complete specification. The sale of secondary generators constructed according to his invention having been interfered with by the appellants as an infringement of their patent, Ferranti in December, 1886, after obtaining the fiat of the Attorney-General under section 19 of the Patents, etc., Act, 1883, presented a petition for revocation of Gaulard and Gibbs's patent of 1882. The grounds (as stated in the particulars of objection) in support of this petition were that the alleged invention was not novel, but consisted solely of a suggestion to use on a large scale the ordinary and well-known mode of deriving electrical action by induction, by means of an induction-coil, from a conductor carrying a varying current, the means employed, and their practical use for such purposes being well known; and, accordingly, that the alleged invention (of Gaulard and Gibbs) made no useful addition to the stock of knowledge existing at the time, and was not a fit subject matter for letters patent. The validity of the patent was also contested on the ground that the claim was for a principle only; that the specification was insufficient, misleading, and erroneous; and also that the invention claimed by the complete specification differed materially from that described in the provisional specification. Prior publication by antecedent specifications and prior user were also alleged in the particulars of objection. Subsequently to the presentation of Ferranti's petition liberty was obtained by Gaulard and Gibbs from Mr. Justice Kekewich, on the terms of paying all costs, to apply at the Patent Office for leave to amend their complete specification by striking out certain parts. The specification as it originally stood, it was argued, seemed to assert that any number of induced currents could be produced by the high-tension current in the main wire without loss of electric energy in the main current—a claim which the petitioner's counsel said amounted to an assertion that the inventors had discovered perpetual motion. By the complete specification as amended the system of Gaulard and Gibbs was stated to consist "of the employment of an alternating current produced by an electro-dynamo machine, and determining by its passage through a number of electrical generators of special construction the formation of induced currents, of which the quality and the value depend only on the construction of the secondary coils of the said electrical generators. The currents generated under these conditions are utilised either by lamps to produce light or by magneto machines to produce motive-power." And the claim as amended was for—"1. The employment of an alternating current of high tension for the generation on a number of secondary generators of induced currents, individually utilised either for the production of light or motive-power. 2. The system of electric distribution such as is laid down in the foregoing statement." The petition was heard before Mr. Justice Kekewich in the course of last year, and on July 9 his lordship gave judgment in favour of the petitioner on the ground that the patentees, Messrs. Gaulard and Gibbs, had not in their specification, as amended by way of disclaimer, sufficiently explained their invention and how it was to be performed. On the question of anticipation, having decided against the patentees, he did not consider himself called upon to examine the evidence and reconsider the arguments as deliberately as he would if he had rested his judgment on that ground; but he expressed the opinion that subject to such revision the patentees had not published to the world, so as to add to the stock of common knowledge, anything which was not already disclosed by some one or more of the earlier specifications. If he could hold the patent to be good on other grounds, he certainly should not hold it to be bad on the point of utility; but being of opinion that what Messrs. Gaulard and Gibbs described in their amended specification as their invention, and for which they claimed a monopoly, was not the proper subject matter of a patent, and that, therefore, the patent granted to them ought to be revoked, his lordship made an order for revocation, with costs to be paid by Messrs. Gaulard and Gibbs.

From this decision the present appeal was brought.

Mr. Aston, Q.C., and Mr. J. C. Graham appeared in support of the appeal; Sir Horace Davey, Q.C., Mr. Moulton, Q.C., and Mr. L. E. Pyke for the respondent Ferranti.

Lord Justice Lindley delivered the judgment of the Court. After stating the nature of the proceedings, which were by way of petition to revoke letters patent, a petition having by recent legislation been substituted for the old action of *scire facias*, his lordship said: The objections taken to the present patent are as follows—viz., (1) that having regard to the previous state of knowledge, the patentee's invention was not one for which a patent could be obtained; (2) that the complete specification is not for the same invention as that described in the provisional specification; (3) that the nature of the invention is not particularly described and ascertained by the complete specification; (4) that the complete specification has been so enlarged by amendment as to destroy the patent; (5) that the patented invention is not new. This last objection is so connected with the first as really to merge into it. In order to deal with these objections, the first thing to be done is to discover what the invention really is according to the patentee's own description of it. For that purpose, the complete specification in its original shape ought to be studied in the first instance rather than the provisional specification, for the former document particularly describes and ascertains the invention, while the latter only states its general nature. If the provisional specification is studied in the first instance, a general, but loose and inaccurate, idea of the real invention is likely to be obtained, and an incorrect conception may be thus formed, and if formed will probably lead to error. Turning, then, to the complete specification as it stood before it was amended, let us see what the invention really is. The patentees claim to have discovered a new system of distributing electricity for the production of light and power. The system consists of a combination of the following particulars—viz., (1) an alternating current of high tension produced by an electro-dynamo machine; (2) the passage of such current through a number of electrical generators of special construction; (3) the formation of such passage of induced currents, the quality and value of which depend only on the construction of the secondary coils of the electrical generators; (4) the utilisation of these induced currents for the production of light or motive-power. The specification and drawings show that a main wire is to be used for the passage of the current produced by the electric dynamo machine, and that this main wire may be miles in length, and that the electrical generators are to be attached to this main wire where wanted. In the first instance, it was said that there might be an unlimited number of these generators. This expression has been amended, and the word "unlimited" has been struck out. This amendment does not, in our opinion, affect the validity of the patent. There may be as many electrical generators as can in practice be wanted, and that is all that anyone would understand by the use of the word "unlimited" in connection with the rest of the specification. Having stated in general terms what the patentee's system or invention really is, it is necessary to ascertain what according to the original specifications is the most essential element in it. This is the specially constructed electrical generators. It is impossible to read the complete specification as originally drawn without seeing that everything turned on these. The quality and value of the induced currents is said to depend only on the construc-

Digitized by Google

tion of their secondary coils, and they are specially claimed by the patentees in their third claim. It is also impossible to read the provisional specification without coming to the same conclusion. It is therefore necessary carefully to study these forms of generators. The electrical generators described in the specification and shown in the drawings are induction-coils. The patentees describe two forms of them. They do not say no others will do ; nor do they point out what in particular is the essential feature of either of them ; but the patentees describe two forms which have certain common features, and there is no reason to suppose that the forms described were not the best known to the patentees when they filed their specification. There is evidence that the forms described will produce the desired results, and there is no evidence to the contrary. Moreover, there is strong evidence that any competent workman could make induction-coils which will produce the desired results by following the specification and drawings, and using such knowledge as he would himself possess. The patentees suppose a main wire 50 kilometres long and a secondary generator—*i.e.*, induction-coil—at every 500 meters. The size of the main wire is not stated. The first example of induction-coil consists of : (1) a central core of soft iron wire capable of being drawn out or pushed into the hollow tube made by the wire coiled round it, and referred to generally. The word in the specification is wire in the singular ; but we understand that any competent workman or electrician would see that a bundle of wires and not one wire was meant, and we so read the specification ; (2) a copper wire about three millimetres in diameter, perfectly insulated in three rows of superposed coils round the core—this is the primary wire, and its length is not stated ; (3) bobbins placed over the cylinder formed as above ; (4) a cable wound round each of these bobbins, and composed of six copper wires of half a millimetre in diameter, each strand being insulated by means of paraffined cotton. This cable of six wires forms the secondary wire of the induction-coil, and its length is not stated. The second example of induction-coil consists of (1) a core like the above ; (2) an insulated primary copper wire, four millimetres in diameter, surrounded by six cables each composed of 12 insulated copper wires of half a millimetre. These cables are the secondary wires, and they are to be arranged parallel to and completely surrounding the primary wire, so as to form with it one cable. The proper lengths of the wires are not stated. (3) The cable thus formed is rolled on a hollow cylinder of wood, say 50 centimetres long and six in diameter ; (4) each layer of spirals is separated from the other by two cylindrical segments of iron two millimetres thick, and without contact to avoid heating ; (5) the extremities of the six fine wire cables are united to a commutator which allows of their being grouped either in tension or quantity. It is apparent, from these two descriptions, that the patentees represent the cable formation of the secondary wires to be important ; quite as important as anything else they described. This, however, is admitted not to be the case. Having thus arrived at the nature of the invention and the mode of carrying it out as described in the specifications, let us turn to the evidence given at the trial. We have studied this with care and have come to the following conclusion : (1) Although some of the specifications in earlier patents come very near the patentees' invention, not of them quite come up to it. No one had previously hit on a combination of (1) an electric dynamo machine producing alternating currents of high tension ; (2) a long main wire ; (3) induction-coils specially constructed, placed along it at intervals for producing light or motion where required. The alleged anticipations all fall short of this. (2) The patentees' system is essentially the combination just mentioned. It was new, apart from the special construction of the induction-coils ; the system is indicated, as Sir William Thomson says, in the drawings to the provisional specification without the letter-press. (3) Nothing really turns on the specially-constructed secondary generators on which the patentees unfortunately laid so much stress. They are not types of any class which has not all their special features. (4) Any competent person, having once seized the idea of the combination shown in the drawings, would see at once how to carry it into effect, and would, without difficulty or further instruction, select an induction-coil suitable for his purpose without adopting either of the specially-constructed coils, and without being told by the specification the lengths of the wires to be used, or the ratio which one of them must bear to the other in length, size, or weight. This is, in our opinion, the true result of the evidence. Any competent electrician would see that a long main wire must, for economical reasons, be as small as circumstances would allow ; that the tension of the current sent along such a wire must be high, far too high to bring into a lamp with safety ; that this tension must be reduced ; that induction-coils could be made to reduce it ; that the lengths and thicknesses of the wires would depend on the object to be attained, and could be ascertained from the law of tension, a formula given in Clerk-Maxwell's book. The evidence, in our opinion, proves all this ; and the state of knowledge was such as to supply the absence of instruction in the specification respecting these details. The nature of the invention is particularly described and ascertained, and two modes of carrying it into effect are sufficiently described to enable any competent electrician who seizes the idea to give effect to it notwithstanding the want of detailed instruction. It is not necessary for us to decide whether the patentees could or could not have obtained a valid patent for their system apart from their specially constructed induction-coils. Perhaps they might have done so. Unfortunately, that was not their intention as originally described. They have so over-estimated the value of their specially constructed generators, and have so drawn and altered their specifications, as to have missed their mark. As already stated, their special form of generator was originally made an essential feature of their system. This was a grievous mistake. They have tried to correct it by amending their complete specification, but in doing so they have entirely changed their front and the nature of their claim. To understand the effect of this amendment it is necessary to see what the patentees have done and what they now claim by their amended specification to be the invention for which they have obtained their patent. The amended specification is vague and ambiguous on this very important point. If confined to a combination of dynamos giving alternate currents of high tension with a main wire and one of the two induction-coils specially described, the patent will be of little or no use to the patentees ; whereas, if construed more extensively, so as to include a combination of such a dynamo with any induction-coil having the properties of the two described, the patent will be of immense practical value, for the evidence shows that any coil which anyone would be likely to make would have such properties. The second of these two constructions is, therefore, obviously that which will be most beneficial to the patentees. It is the construction which the patentees have laboured to maintain. The whole of their evidence was addressed to this. No serious attempt was made to show that there was any merit in the two specially-described generators except their movable iron wire cores, which almost all induction-coils had in 1882. We are satisfied that no other construction is worth contending for, and it is, in our opinion, the true construction of the specification as amended. The specially-constructed generators are no longer claimed, either separately or as essential parts of the combination. They are seen to have no particular value, and are dropped accordingly. This construction of the amended specification renders the patent hopelessly bad in law ; for, first, on this construction the invention is not the same as that described in the provisional specification, but an entirely different invention ; and, secondly, on this construction, the amendment of the complete specification has greatly extended the scope of the patent. As already shown, the essence of the invention, as described in the complete specification in its original shape, and as set forth in the provisional specification, lay in the use of a specially-constructed generator (or combination), which the patentees believed to be superior to all others, and, in fact, to have magical powers ; and if they throw this over they so far depart from their invention as described in these documents as to render the patent they have obtained for it worthless and incapable of being supported. The law upon this point is perfectly well settled, and it is useless to refer to authority for it. This view of the case renders it unnecessary to consider whether the patent could be supported if it were construed narrowly and confined to a combination for an alternating dynamo with induction-coils constructed like one of the two described in the specification. This point was not much argued. The decision in favour of the patentees would be of little use to them, and the petitioners do not care which way it is decided, as they say they do not use that particular combination. This point, if it fairly arose, would, we think, be found full of difficulty, considering the evidence given at the trial. But, having regard to the terms of the specification and the real contest between the parties, we do not think it calls for decision. In our opinion the patent is bad, and the appeal must be dismissed with costs.

COMPANIES' REPORTS.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.

Report of the directors to be submitted to the ordinary general meeting, to be held at the Cannon-street Hotel, on Wednesday, March 13, at 12 o'clock :

In view of the fact that since the date of the last general meeting two interim reports have been issued to the shareholders, the directors consider that the usual *résumé* of the year's work admits of some curtailment in this instance, and they now confine themselves chiefly to a statement of the present position of the corporation, and to an explanation of the yearly accounts. In the special report of the 18th July last, the directors explained in some detail the circumstances attending the litigation with the Edison and Swan United Electric Company in regard to incandescence lamp patents, and reported the decision which Mr. Justice Kay had given in favour of the corporation on the Edison patent. The interim report of the 3rd October last contained a general statement of the position and prospects of the corporation at that time, and of the work accomplished during the first nine months of the year. The directors are glad to be able to announce that the expressions of confidence with regard to the future of the electrical industry contained in their previous reports, are fully borne out by the progress effected during the past year. An extensive and more genuine demand for electric light and power has made itself evident, to the great benefit of the industry generally and to the corporation individually, as will be seen from the satisfactory character of the accounts now presented of the corporation's affairs. It is now generally admitted that the amendment of the Electric Lighting Act of 1882, which extends more favourable terms to the electrical contractors, and thus justifies the investment of capital in central installations for the supply of electric current, will produce highly beneficial results. As a matter of fact, although only a few months have elapsed since the Amendment Bill, introduced by Lord Thurlow, became law, considerable impetus has already been given to the business, and there is now much greater activity in all branches of the industry. The improvement in the general position of the corporation which has followed upon the revival of business in this direction is, however, not yet exhibited in the accounts now submitted, as the orders which have been received, in connection with the supply and erection of plant for central stations, are still in progress. The marked improvement, which is seen from the accounts, is due almost entirely to the growth of the ordinary business. There are also indications that the amendment of the Electric Lighting Act will have a salutary effect in other directions, and by inspiring renewed confidence tend to

Digitized by Google

establish a better understanding among the various electrical manufacturers and contractors. United action where common interests are involved is greatly to be desired, and a diminution of the unhealthy competition which has prevailed during the recent depression is necessary to enhance the profits of the business. The formation of an Electrical Trades Section of the London Chamber of Commerce, affording, as it does, opportunities to the principals in the various electrical firms for discussing common interests, is a step in these directions.

The result of the past year's work is, under all the circumstances, highly satisfactory. As compared with the previous year, the volume of business shows an increase of about 38 per cent. and the gross profit an increase of 70 per cent., while the standing charges have increased by only about 7 per cent. The net balance of profit, after providing for depreciation and bad debts, is £12,885. 4s. 9d., which is equal to more than 5 per cent. upon the entire capital of the corporation. It is to be remarked that this profit has been earned almost entirely upon the ordinary transactions of the year, and does not include the profit accruing from the central station work now in hand, and that there are still other important fields from which the corporation are able to derive revenues. The shareholders will therefore recognise that the business of the corporation is now not only established on a reliable profit-earning basis, but that very sanguine expectations with regard to the future development of the business and payment of dividends are justified.

The contracts carried out by the corporation during the year include important work in almost every department of the electrical industry. The lighting of the Melbourne Centennial Exhibition, which proved eminently successful, and comprised the largest installation of the kind yet erected, was carried out almost entirely by means of the corporation's apparatus, supplied at very short notice to the Australasian Electric Light, Power, and Storage Company. The contract secured for the arc lighting of the main building and grounds of the Glasgow Exhibition of 1888 was carried out to the thorough satisfaction of the executive committee, as will be seen from the following letter received from Sir W. Thomson: "As chairman of the lighting committee of this exhibition, I have much pleasure in intimating to you my entire satisfaction with the manner in which your contract was carried out. During the entire period the 520 arc lamps installed by you have worked with the greatest regularity and steadiness." The illuminated fountain installation effected by the corporation at the Barcelona Exhibition formed one of the most attractive features of the exhibition, and was universally described as far surpassing all previous similar undertakings. This contract met with the entire approval of the exhibition authorities, who have given the corporation their highest award of a gold medal. The corporation have also been awarded a diploma in respect of their contract for lighting part of the Brussels Exhibition. Amongst the installations on ships completed by the corporation during the year, may be particularly mentioned those on board the Castle Mail steamers "Rosslyn Castle," "Hawarden Castle," and "Norham Castle." Numerous installations have been carried out in private residences, factories, shops, offices, theatres, and other premises throughout the United Kingdom and abroad, and particular reference may be made to the completion of an important incandescence installation of 1,000 lights at Blenheim Palace, for his Grace the Duke of Marlborough, and also to the lighting of Professor Piazzi Smythe's residence at Ripon. The negotiations with the Honourable Commissioners of Sewers for lighting the City of London have been continued; and it is confidently expected that at an early date specifications will be issued and tenders invited for lighting various sections of the City, for which the corporation will be in a position to submit a proposal with good prospect of success.

The advance in the different technical branches has been of a very marked character, and highly important results have been achieved, notably the perfection of the alternating current system of distribution, which enables electric current to be supplied economically over large areas without any risk of danger to the public. The corporation have designed a complete alternating current system which is now perfect in every detail, and has been in successful operation during the past year. This apparatus has met with great favour since its introduction, and is now being manufactured on a large scale. The Victoria dynamo machine for running incandescence and arc lamps in parallel has been improved in design and mechanical construction, and is generally recognised as one of the most efficient machines for the purpose in the market. This dynamo has been found to lend itself admirably for use in connection with direct driving engines at slow speeds for installation on shipboard, and has been manufactured in large numbers for this application. The special engines supplied by the corporation from the designs of their superintending engineer, Mr. Raworth, meet with a ready sale, and constitute an important feature of the business. The corporation's trade in incandescence lamps has been considerably extended, and their Victoria lamps have secured a wide reputation for durability and economy. When the Cheesbrough patent was upheld by Mr. Justice Kay, in the recent action of Edison and Swan *versus* Holland and others, the corporation at once devoted attention to the production of a lamp in which the Cheesbrough process of flashing could be dispensed with, and their efforts were so successful, that the present form of Victoria lamp ranks as one of the most efficient in the market. The directors are glad to be able to state that the action referred to in the last annual report, which the corporation instituted in 1887 against the Orient Steamship Company, who were using dynamo machines, made by Messrs. King, Brown, and Co., of Edinburgh, in infringement of the Brush patent for compound winding, was decided wholly in favour of the corporation by Mr. Justice Chitty in December last, and the corporation were granted a certificate of validity of the patent, costs, and enquiry as to damages. Meanwhile, Messrs. King, Brown, and Co. have brought an action in Scotland for the revocation of the patent, and this case is now before the Court. With the above exception, every dynamo manufacturer of importance in the country has recognised the corporation's claim, and the royalties now received constitute an important source of revenue. In this matter the policy of the directors has been, while not harassing the trade or interfering with the growth of the industry, to protect the interests of the shareholders by charging a small royalty for the use by others of the corporation's patent. The directors, however, have no alternative but to resort to legal procedure when the usual commercial methods of protecting the corporation's rights, and of enforcing their just claims, fail. The action of the Edison Swan Company against the corporation for alleged infringement of the Edison patent in the manufacture of Victoria incandescence lamps is now under appeal to the House of Lords, the Court of Appeal, which had previously decided in favour of the Edison patent, in the case of Edison and Swan Company *v.* Woodhouse and Rawson, having recently reversed the decision which Mr. Justice Kay gave after a most exhaustive hearing extending over 22 days. In view of the fact that the House of Lords will not be bound by the decision of the Court of Appeal in the Woodhouse and Rawson case, and that the issue to be raised will in many respects be a new one, the directors are advised that there is every prospect of the decision of Mr. Justice Kay in favour of the corporation being sustained. The directors deeply regret the existence of this litigation, which is not only costly, but is a very great disturbance to the proper conduct and development of the ordinary business. Litigation is, however, not always avoidable, and that relative to incandescence lamp patents has been rendered necessary by the action of the Edison Swan United Electric Light Company. That company and the corporation both hold patents for the manufacture of incandescence lamps, and it has always been the earnest desire and endeavour of your directors to respect the interests of the two companies, and of the industry generally, by effecting a settlement equitable and honourable to all parties. In this effort, however, they have not as yet been successful, and have had no recourse but in the interests of the shareholders to defend to the utmost the action instituted by the Edison Swan Company. The corporation have much to gain in the future by freedom from interference in their business as manufacturers of incandescence lamps under the various patents they hold, but, unlike the Edison and Swan Company, they do not rely for their revenue mainly upon the manufacture of these lamps, inasmuch as the corporation's trade in these articles at present amounts to scarcely 10 per cent. of the total volume of their business.

The capital account shows an increase of £4,640, which arises out of the issue, under the resolution passed at the general meeting in February, 1887, of 1,160 new shares. The increase in the patents, development, and goodwill account of £1,749. 1s. 10d. is due to development of new inventions, and to the usual annual payments for maintenance of existing patents. The profit and loss account includes a satisfactory profit derived from the Austro-Hungarian branches. This new department of the business has, during the past year, developed in every way satisfactorily, and bids fair to prove an important source of income in the future. The central lighting stations worked by the corporation are now also yielding good profits. The directors consider the present a fitting opportunity for taking a general survey of the advance made during the five years which have elapsed since the reduction of capital in 1884, and with this view they submit a diagram showing the fluctuations during that period in the volume of the business, the general charges or expenses of management, and the gross profits. To facilitate comparisons between one year and another, the actual figures are shown on the diagram in percentages, the figures for the year 1883 being taken as represented by 100. It will be seen that the volume of business in 1888 is to that of 1883 as 307 is to 100, showing an advance in the five years of upwards of 200 per cent., and while the gross profits have increased in the ratio of 100 to 342·9, or over 242 per cent., the standing charges have fallen in a ratio of from 100 to 65. The above figures do not take cognisance of the business effected through the continental branches. If this be added, as shown in the diagram by means of dotted lines, it will be seen that the advance of the corporation's business is even more satisfactory, notwithstanding that the standing charges are relatively higher on the continent than in England, which is due to the fact that the business carried on there by the corporation is still young; and it is probable that a much larger amount of trade could be effected without any material increase in the expenses of management. The directors think it will be recognised by the shareholders not only that the affairs of the corporation have, during these five years, been conducted with energy and economy, but that, having regard to the hitherto undeveloped condition of the industry, and consequent difficulty and expense of working up a new business, the results must be considered as highly satisfactory and encouraging. With regard to the prospects for the current year, the directors have every confidence in a still further improvement, the orders during the first two months of this year being more than double the orders received during the corresponding period of any previous year.

The directors who retire this year by rotation are Lord Thurlow and Colonel Steuart, who, being eligible, offer themselves for re-election. Messrs. Cooper Brothers and Company, the auditors, also retire, and offer themselves for re-election.

CITY NOTES.

West Coast of America Telegraph Company.—The receipts of this Company for the month of February amounted to £5,900.

Great Northern Telegraph Company.—The traffic receipts of this company for the month of February amounted to £19,600.

Eastern Telegraph Company.—The receipts of this Company for February were £54,611, as against £51,261 for the same period of 1888, or an increase of £3,350.

Eastern Extension Telegraph Company.—The traffic receipts of this Company for the month of February were £37,584, as against £38,795 for the same period of 1888.

Digitized by Google

Brazilian Submarine Telegraph Company.—The traffic receipts of this Company for the week ended March 1 amounted to £5,327.

West India and Panama Telegraph Company.—The receipts of this Company for the half-month ended February 28 were £2,696, against £3,201. The November receipts, estimated at £5,203, realised £5,288.

Western and Brazilian Telegraph Company. — The traffic receipts of this Company for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Company, were £4,467.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of this Company during February was 4,151, estimated to produce £3,200, against 4,535 messages, producing £3,666. The receipts for November, estimated at £3,100, realised £3,107.

Anglo-American Brush Electric Light Corporation, Limited.—An available sum of £12,885 is shown in the accounts of the Anglo-American Brush Electric Light Corporation, Limited, for the year 1888, this being inclusive of £2,562 brought forward. The Directors do not propose any distribution.

Direct Spanish Telegraph Company, Limited. — This Company, for the half-year ended December 31, recommend a dividend at the rate of 10 per cent. on the preference shares, and one of 4 per cent. per annum on the ordinary shares, tax free, making, with the previous distribution, a dividend at the rate of 4½ per cent. for 1888 on the ordinary shares, against 4 per cent. in 1887, carrying forward £723. The traffic receipts for the month of February are estimated at £2,008, as against £1,858 in the corresponding period of last year.

Companies of the Month.—The following electrical companies have been registered during the past month :

Graphophone Syndicate, £10 shares	£100,000
Mines and General Telpher Company, £1 shares	4,000
Nottingham Electric Light and Power Company, £10 shares	10,000
River Plate Electricity Company, £10 shares	500,000
Railway Automatic Electric Light Syndicate, £25 shares ...	10,000

PROVISIONAL PATENTS, 1889.

FEBRUARY 25.

3324. **Improvements in the method of and apparatus for operating the carbons of arc lamps.** Frederick Thomas Schmidt, Sunbridge-chambers, Bradford, Yorkshire.

3327. **Signalling by electricity on railways by means of the train in motion.** William Ballard, Bull Ring, St. John's, Worcester.

3330. **Improvement in the application of the electric incandescent light to be used by man or beast.** John Hartness, 59, Campbell-street, Newcastle-on-Tyne.

3345. **Improvements in electric light emitting and other conductors.** James Clegg, 6, Gray's-inn-square.

3350. **An improved instrument for measuring currents of electricity.** Sir Charles Stewart Forbes, Bart., 21, Finsbury-pavement, London. (Complete specification.)

3363. **Improvements in the manufacture of incandescent electric lamps.** John Wigham Edmundson, 46, Lincoln's-inn-fields, London.

3365. **Improved apparatus for facilitating the laying of electrical conductors, chiefly designed for military purposes.** Leo Kamm, 4, South-street, Finsbury, London.

FEBRUARY 26.

3396. **An improved electric checking apparatus for beer engines.** Francis Edward Macmahon, Albany-chambers, Haymarket.

3401. **Improvements in or connected with current regulators for dynamo-electric machines.** Elmer A. Sperry, 1, Quality-court, Chancery-lane. (Complete specification.)

3402. **Improvement in apparatus for metering electric energy.** William Harding Scott and Laurence, Paris, and Scott, Limited, Gothic Works, King-street, Norwich.

3420. **An improved method of automatic regulation in dynamo machines.** Josiah Sayers, 24, Glycena-road, Lavender Hill.

3456. **Electric circuit couplers.** Stanley Charles Cuthbert Currie, 24, Southampton-buildings, London. (Complete specification.)

3461. **Improvements in and relating to electric regulators or balances.** Frédéric Victor Maguaire, 45, Southampton-buildings, London.

FEBRUARY 27.

3499. **Improvements in electrical telegraphs for use on board ship.** Arthur Mechan, 62, St. Vincent-street, Glasgow.

3502. **Improvements in or connected with processes of manufacturing iron wherein the iron is subjected to an electric treatment.** Alfred Griffiths Greenway, Benjamin Franklin Babcock, and Brainerd Radcliffe, 15, Water-street, Liverpool.

3533. **Improvements in the extraction of copper and zinc from their ores, as also of the precious metals contained therein by electrolysis and apparatus therefor.** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London. (The firm of Siemens and Halske, Germany.)

3540. **Improvements in electric danger alarms for railway block-signals.** James Henderson Hunter, 191, Fleet-street, London. (Complete specification.)

FEBRUARY 28.

3550. **Improvements in holders for incandescence electric lamps.** Walter Rowbotham, 25 and 27, Sidney-street, Salford, Manchester.

3556. **An improved method of regulating the current developed by dynamos or magneto-electric machines, and the power of electric motors.** Oliver Firth and Edward Wright Crabtree, 27, Kirkgate, Bradford, Yorkshire.

3558. **Method of obtaining aluminium continuously in an electrical furnace.** Henry Kenyon, 3, Kimberley-street, Princes Park, Liverpool.

3569. **Electrical measuring instruments.** J. J. Bowman and V. G. Lironi, Walnut Tree House, High-road, Leytonstone, Essex.

3580. **An improved electric bell or gong.** Frederick Herbert Berry, 186, Fleet-street, London.

MARCH 1.

3629. **Improvements in electric meters.** Robert Snowdon, 70, Market-street, Manchester.

3662. **Improvements in electric railway signals.** Theodore Al'Burtis Putnam, 55 and 56, Chancery-lane, London.

3671. **Improvements in or relating to winding and synchronising clocks by electricity.** Alfred Julius Boult, 323, High Holborn, Middlesex. (René Joseph Pouchard, France.)

3674. **Improved method of and apparatus for distributing and regulating electric currents.** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London. (The firm of Siemens and Halske, Germany.)

3679. **An improved apparatus for regulating electric currents and for other purposes.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.) (Complete specification.)

MARCH 2.

3687. **Improvements in apparatus for establishing electrical connection, and also for breaking the same at will at any desired distance from the operator.** William Joseph Starkey Barber-Starkey, and Frank Geere Howard, 36, Cleveland-street, London.

3697. **Improvements in the construction and application of transformers for the distribution of electricity for lighting and other purposes.** John Augustine Kingdon, 29, Marlborough-hill, London.

3708. **An improved method for joining electric conductors.** John Kent, 9 and 10, Railway-approach, London Bridge.

SPECIFICATIONS PUBLISHED.

1887.

NOTES.

Electric Weighing Machine.—An electric weighing machine, the invention of Mr. W. Snelgrove, will be exhibited by Messrs. W. and T. Avery, for the first time, in the Paris Exhibition.

St. Luke's.—The members of the St. Luke's Vestry are considering their electric lighting scheme with the aid of copies of the Parliamentary Bill promoted for this district. The special meeting called for settling the question stands adjourned for a month.

Bermondsey.—The question of electric light was brought forward at the last meeting of the Bermondsey Vestry, and it was resolved to give consent to the applicant company, providing that they agreed to assent to the proposals of the Vestry in relation thereto.

Southwark.—The St. Saviour's (Southwark) District Board of Works have consented to the application for provisional orders on behalf of the Metropolitan Electric Supply Company and the London Electric Supply Corporation, subject to certain restrictions being allowed.

Electricity on the Metropolitan.—The Metropolitan Railway Bill, which empowers the company to use electricity as a motive power, and to enable them to run over the Aylesbury and Buckingham Railway Company, passed the Examiner upon Standing Orders in the House of Commons on Monday last.

Motors for Electric Light.—At the Society of Arts on Wednesday, 20th inst., at 8 p.m., Prof. A. B. W. Kennedy, F.R.S., will read a paper on the "Objects and Methods of the Society of Arts' Motor Trials." The medals awarded at the Society of Arts' motor competition will be presented during the evening.

Edison's Patents in Canada.—The Commissioner of the Patent Office, Ottawa, gave his decision on the 8th inst. in the cases arising from the Edison incandescent patent in Canada. He cancelled the patent on the ground of illegality, and as not being manufactured in Canada, according to the provisions of the statute.

Dudley.—Alderman Bagott is in favour of introducing a competitive system to the gas into the town of Dudley, and at the last meeting begged the Town Council to do all in its power to favour the electric light. At present, however, nothing was determined, but it was agreed to send a deputation to the gas company to endeavour to get a reduction.

Lubeck.—Lubeck, as is well known, was the first town in Germany to have an electric light station of its own. There are now 2,386 incandescent lamps, and 36 arc lamps. The balance sheet for 1888, just published, shows an income of 67,143 marks, and expenditure 45,126 marks. Interest on capital at 3½ per cent., and depreciation at 1 per cent. are given at 15,300 marks, leaving a surplus of 6,717 marks.

Royal Meteorological Society.—Dr. W. Marcet, F.R.S., will deliver an address on "The Sun—its Heat and Light," at 25, Great George-street, on Wednesday next, at 7 p.m., illustrated by experiments, after which the exhibition of new actinometers, radiation apparatus, meteorological instruments. The exhibition will be in readiness for the meeting of the Civil Engineers on Tuesday, the 19th, and will remain open till Friday, the 22nd inst.

Clerkenwell.—At the meeting of the Clerkenwell Vestry, on Monday, an application from the London Electric Supply Corporation and the Metropolitan Electric Supply Company for powers to authorise the companies to acquire lands, erect stations, and supply electricity for public and private use within the parish of Clerkenwell was agreed to, subject to the repair of the roads by the companies for a period of three years.

Floods at Bath.—The electric lighting on the Thomson-Houston system has been started in Bath for some months, with one or two dynamos in a temporary building pending the starting of the new central station. The recent floods, which have caused such extensive damage in the West of England, threatened the destruction of the dynamos at Bath, but fortunately they were able to be moved before the water got sufficiently high to touch them.

Electric Submarine Boat.—A large electric submarine boat is to be shortly constructed in London. The model has been in operation for some weeks at Endell-street Baths, and the syndicate which applied for £20,000 had £90,000 offered yesterday, and will proceed at once with the building a full size boat. The boat is to be worked with accumulators, and the motions of raising and submerging the boat are brought about with three screws.

Electrical Engineers, Students' Meeting.—A meeting was held on Friday, the 8th inst., at 8 p.m., Mr. Guy C. Fricker, A.I.E.E., in the chair. The discussion on Mr. H. W. Handcock's paper on "Ship Lighting and the Aspects of Electrical Industries in the Colonies" was opened by Mr. J. Rance, jun., and continued by the chairman and Messrs. Müller and Childs. Mr. Handcock replied, and a vote of thanks to Mr. Fricker for presiding terminated the proceedings.

Dartford Distributing Station.—A central station is proposed, we hear, at Dartford. The current is intended to be supplied from the Deptford station, but the London Electric Supply Corporation will have enough to do to supply and maintain their London customers, and the current will be hired out to a subsidiary company, who will manage the entire distribution, and themselves be saved the bother of having more machinery to look after than a giant 10,000 transformer or two in a cellar.

Useful Electrical Questions for Tropical Climates.—(1) Is the coefficient of variation of resistance with temperature mathematically correct for copper coils, and more especially for galvanometer-coils? (2) Is capacity variable with temperature? (3) Are high resistance coils of platinum-silver reliable, or is it not a fact that, under certain climatic conditions, they show residual charge—that is, act to a certain extent as a secondary cell, destroying the accuracy of tests?

Competition of Electric Meters.—The competition of electric meters proposed by the Council of Paris for a prize of £100 and other amounts, will take place in June. The meters must be sent, in closed packages with an accompanying notice, on 15th to 25th May next, to the Bureau du Sous-Directeur des Travaux, Hotel de Ville, Paris. In return for the stipulated prizes the Council takes the right to manufacture the meter selected, for use in the municipal central stations in Paris, without payment of further royalty.

People's Lectures.—The lectures by Mr. W. Lant-Carpenter at the Polytechnic, Regent-street, on "Electricity

Digitized by Google

in the Service of Man," under the University Extension scheme, have been very successful, about 1,250 attending each time, and some hundreds turned away from the doors. The right class attended, too, being largely consistent of adult artisans. Succinct and reliable syllabuses were given away for the audience to study over at home, giving reference to useful works on the subject for those who cared to take the matter up further.

Chatham.—The Chatham Electric Light Company have been very successful with their station, and the inhabitants are well satisfied with the light. The water supply available was not sufficient, and a well was successfully sunk last week which gives the output of 25,000 gallons per hour. The company have met with considerable success, and they are so satisfied with the progress that has been made in the adoption of the light that it is stated they are now about to make large additions to their plant, for which more capital will be taken up.

Electric Traction in the Ascendant.—Proposals have been made to the Liverpool Tramways Company to install an electrical system without expense over two miles of the Liverpool tramways, agreeing to restore the line if the company are not satisfied with the result. Liverpool ought to be the scene of the next success in electric traction in England. We are getting along at last. Tramway directors are waking up, and the practical working line we illustrate this week should initiate a boom in conductor systems. Storage systems are not behind, as we shall shortly see, and between the two the public ought to travel well.

Electric Engines on the Elevated.—The Daft motor, "Benjamin Franklin," on the Elevated Railroad, New York, has lately drawn nine carriages, the greatest number ever drawn in one train upon the Elevated Railroad. Within the last few weeks experiments with this same engine have also shown that it can draw a load of four goods cars, loaded with railroad iron, with the same ease as a locomotive. The success of this engine is such that a larger and more powerful motor is now in process of construction at the Daft Electric Light Works, which will be able to draw with ease six carriages at a speed of 30 miles an hour.

Alternate Current Motors.—It is whispered that Mr. Ferranti is hard at work on having an alternate current motor ready for the general distribution from Deptford. Two of the four proposed methods of constructing these motors have been tested and discarded; all we can say is that one of the other two, it is hoped, can be adopted practically. The question of efficiency will, of course, settle the question, and if the efficiency is satisfactory we might see a rival tram-line to that we describe this week, run on the high-tension system from Deptford. Some of the directors of the London Electric Corporation are interested also in the series system.

Electric Light at Windsor Castle.—The Queen, says the *Lady's Pictorial*, has expressed her satisfaction with the electric lighting of the corridors at Windsor, and, indeed, the perfection to which incandescent lamps are now brought is irresistible, but her Majesty is still proof against the persuasion of Princess Beatrice to have the light carried into her private apartments, remarking softly to her daughter at the dinner-table a night or two ago: "I am not prejudiced, but at my age it is not worth while changing my habits"—a sentiment not unlike that of the old Kaiser Wilhelm, though his reason for turning down the smoky lamps had more of pathos in it.

Steel Forgings for Electrical Machinery.—During a recent visit to Sheffield we were interested in being shown over the works of Messrs. Moss and Gamble, at Bower-spring and Wadsley, where steel melting, file cutting, and tool-making and heavy steel forging is extensively carried on. Messrs. Moss and Gamble make large quantities of steel forgings of all shapes and sizes for use in engines and electrical machinery, and have for long time supplied Edison, Mather and Platt, W. H. Allen and Co., and other well-known electrical engineers, with best steel forgings. We saw some large steel forgings for Messrs. Allen's engines in progress at the time of our visit.

City Lighting.—At the Bishopsgate Ward Club, on Wednesday, Mr. Laidlaw Cross resumed the subject of electric lighting in the City, and moved, "That the lighting of the City by electric light should no longer be delayed." For some years, he stated, the City had made several attempts or experiments to light it by electricity. There had been several negotiations with different electric light companies, but they had all fallen through. There were now three capable companies ready and willing to contract, and he thought that the hands of the Commissioners of Sewers should be strengthened in their endeavours to use electric light in the City. After a short discussion, the resolution was carried unanimously.

The E.P.S. Co. in St. Martin's-in-the-Fields.—The Vestry of St. Martin's-in-the-Fields, at their meeting last week, passed a resolution granting the provisional order applied for by the Electrical Power Storage Company, under the Electric Lighting Act, for the supply of electricity within the parish, and the Bill will therefore go forward in due course. There has been considerable opposition, but it seems that, after all, justice has declared itself, inasmuch as the field is now once more open. We are not in any way advocating one system more than another, but we are satisfied to note that in this way the balance of power has been preserved, and that, whether it be a question of storage or direct supply, there will at least be fair play, and we await further developments.

An Electric Valve.—An arrangement of electrodes is described by M. Neyreneuf, in the *Journal de Physique*, which the discoverer calls an electric valve, as the current can be passed one way, but not in the other. M. Neyreneuf had been experimenting in electrolysis with aluminium electrodes. With a voltameter constructed with two aluminium electrodes, with dilute acid as electrolyte, and with an alternating current, he found that pure hydrogen was evolved at both electrodes, itself a curious enough result. On constituting an arrangement with one electrode of aluminium and one of mercury, with distilled water as electrolyte, the current was found to pass in one direction only, a somewhat extraordinary result which might possibly prove useful practically for regulation of currents.

Barnet.—Last week we inserted a note under this heading, which must be unreservedly withdrawn. There are always two sides to questions relating to business matters, and in this case we are pretty certain that the reasons why the Statter dynamo is not to be used at Barnet have nothing to do with electrical or commercial efficiency. It is needless to enter into detail as to how a particular note was inserted, but we may go so far as to state that its insertion broke one of the rules which had previously been faithfully followed in this paper—viz., that a technical

journal has nothing to do with purely trade squabbles. Since the note appeared we have received other information regarding this make of dynamo, and, without exception, the users agree that they have found the Statter machine to be a good one.

Willis Electric Ship Signal.—The new electric ship signalling apparatus of Mr. J. B. Willis is much appreciated by marine engineers, and is rapidly becoming adopted for all large vessels. Many of the largest warships have already been fitted with these instruments, and the working has been favourably reported upon, especially from Captain May, of the "Imperieuse," now in Chinese waters. One captain using the Thames frequently, states that with the old mechanical apparatus he used invariably to post men to call orders down to the engine-room, but that now he relies entirely upon his electric signalling apparatus, taking his vessel into dock entirely by its working. On one occasion he was only saved from a certain collision by the smartness with which he was able to transmit orders to the engineer by the electric signaller.

Electrical Presents.—Electric light fittings seem to be becoming fashionable as wedding presents. A recent presentation to the Prince and Princess of Wales by the Colonial Committee, on behalf of the colonies, to celebrate the "Silver Wedding," took the form of a clock and candelabra, with two large wall brackets fitted for electric light. It is an example many technical persons might worthily follow in their own sphere, as marking their esteem and at the same time giving an inducement to their friends to spread the introduction of the electric light in their homes. Wedding presents are not easy to be thought of, and many less pleasing presents than, for instance, an artistic cut-glass, hammered copper, or wrought-iron electric fitting, or the lovely natural foliage "metalli-floral" pendants, lately introduced, might be given to persons living in a district where electricity is likely to be supplied.

Extension of West African Cables to the Cape. On Thursday, the 7th inst., the ss. "Silvertown," Capt. Thomson, belonging to the India Rubber, Gutta Percha and Telegraph Works Company, with about 800 miles of cable on board, sailed from Greenhithe for Teneriffe, *en route* for Bonny (Gulf of Guinea), to lay a cable from that town to the Portuguese island of Principe, and also between St. Paul de Loanda, Benguella, and Mossamedes. The expedition is under the charge of Mr. H. M. Gray, C.E., assisted by Messrs. Theophilus Smith, C.E., Henry Benest, C.E., and Rymer Jones, C.E. Mr. R. E. Peake, C.E., represents the well-known firm of Clarke, Forde, and Taylor, engineers to the companies for which the cables are to be laid. It is expected that communication will be completed in about three months' time. The "Scotia," Capt. Cator, belonging to the Telegraph Construction and Maintenance Company, had previously sailed on Saturday, the 2nd inst., to lay some 1,400 miles further south. When both these groups of cables are laid, the Cape will possess duplicate telegraphic communication with Europe.

Static Electricity and Incandescent Lamps.—Mr. C. S. Bowie, in the *Electrical World*, calls attention to the effect of static electricity in shortening the life of incandescent lamps. In the case he mentions, five lamps, notorious for short life, were situated over some calender rolls. As these rolls generate a good deal of frictional electricity by the passage of the dry paper over them, he was led to believe that this was the cause of the lamps burning out so soon. In order to see what effect frictional electricity had on an incandescent lamp, and also to find a remedy for the above case, a lamp and socket, connected with a cord and attaching plug, was held near a dry fast running leather belt. As soon as the lamp was placed near the belt, the carbon began to vibrate violently—so violently that it was soon broken off. The same effect took place when the current was turned off the lamp. On placing a wire guard, similar to that used over billiard-tables, around a lamp and held near the belt, no effect was noticed on the light or carbon. Wire guards were then placed around the lamps in use near the calenders, and since then there has been no complaint.

Extension at Taunton.—The success of the Taunton Electric Lighting Company, having paid a first year's dividend of five per cent., and a second year's dividend of six per cent., with a balance forward from the two years of £207, has given the directors justification to think that extended working will be equally profitable. They accordingly announce that a further issue of 1,000 shares at £5 will be now made, to enable them to extend their works. A site has been selected at Tangier, near the gas company's works, where a model electric light station will be erected, with new engines of the most economical type. The company employ the Thomson-Houston arc system for the public lighting, and express much satisfaction with the performance of both the dynamos and the lamps. The question of private house lighting, for which there is now a considerable demand in Taunton, will also be attacked. We shall evidently see the efforts of Mr. Massingham result before long in a real central distribution station for public and private lighting in this town. The success achieved by the promoters of electric lighting in Taunton should greatly encourage the various authorities who are anxiously enquiring into the merits of electric lighting.

Electricity v. Gas in Switzerland.—Although it is constantly said (writes a correspondent of *Industries*) that the existing gas works have in no wise suffered by the introduction of the electric light, yet the manufacturers of gas apparatus are complaining of scarcity of orders, there being hardly any new gas works now erected in Switzerland. It is easily understood that the electric light would be preferred to gas in such situations where water power is abundant; but the experience of the last year or two shows that the electric light is cheaper than gas light, even in such cases where the power has to be obtained from steam engines, and hence large manufacturers who have not already a gas supply prefer to put up an electric light installation instead of a local gas plant. In this connection should be mentioned the repairing shops of the St. Gothard Railway, at Bellinzona, which have been amongst the first to introduce the electric light, and this example has stimulated the municipal authorities of Bellinzona, Lugano, and even the small village of Faido, to invite plans and tenders for central electric light stations. In Luek, which receives a splendid new casino, the electric light will be used as a matter of course. A large billiard factory in Berne has also been fitted up with the electric light, and the same illumination is employed in the town theatre of Zug; and these examples might be multiplied to any extent. It is remarkable that the incandescent gas light, although a year or two ago it appeared to give much promise, has never taken a firm hold in Switzerland.

Westminster.—At a meeting of the St. Margaret's and St. John's (Westminster) Vestry, on Wednesday, Arch-

Digitized by Google

deacon Farrar in the chair, the Parliamentary Committee reported that they had had the following electric lighting schemes before them: Kensington and Knightsbridge Electric Lighting Company, Metropolitan Electric Supply Company, London Electric Supply Corporation, Westminster Electric Lighting Company, St. George's (Hanover-square) Electric Lighting Company, and the House-to-House Electric Light Supply Company. They recommended that objections should be lodged agianst the whole of them. The committee further reported that they had received communications from the Board of Trade notifying that the Board had refused the applications for licenses by the Metropolitan Electric Supply Company and the London Electric Supply Corporation, on the ground that in matters of such magnitude Parliament should be afforded an opportunity to review the Board's decision. The committee was still proceeding upon the reference by the Vestry, empowering them to fully enquire into the whole question of electric lighting, with a view to the Vestry undertaking the supply of the light in that district themselves. A letter was read from the secretary to the House-to-House Electric Light Supply Company, inviting the Vestry to inspect the works at their Kensington Electric Lighting Central Station, adjoining West Brompton Station, and now in working order, and offering to explain their system for the guidance of the Vestry in dealing with the electric lighting question. On the motion of Mr. J. B. Batten, this invitation was referred to the Parliamentary Committee; and the foregoing report and recommendations were unanimously adopted, at the instance of the same gentleman.

Electric Light in a Hydropathic.—Among Scotch health resorts, Crieff, in the valley of the Earn, has always held a foremost place. It is largely patronised by the residents of Glasgow, Edinburgh, and Dundee, and among hydropathic establishments, that of Strathearn House, Crieff, has become the best known, and is the most frequented of any, even in midwinter having usually over 100 visitors. It is not therefore surprising that the directorate should desire to add to its other attractions that of the electric light, which is admirably suited to such an institution. At the beginning of the present year it was decided to lay down plant capable, not only of lighting the public rooms of the building itself, but also of supplying current to several motors scattered about the outbuildings, and to one or two villas adjacent. Amongst other things, it is intended to supplement the water-power driving a threshing machine in the stables by means of an electric motor. The power is supplied by means of a double-acting high-speed Griffin gas-engine of 24-brake h.p., nearly running at 200 revolutions per minute, which drives a Paris and Scott dynamo, giving 100 volts and 120 amperes. The engine-room is underground, and close by it is the accumulator-house, where it is intended to place 54 of the E.P.S. Co.'s largest cells to increase the capacity of the station. A main switchboard in the engine-room, and a controller in the manager's office, give complete control over the number of lights in use. All circuits are protected by Anderson and Munro's fusible cut outs and safety switches. The lamps are either the Sunbeam lamps of 400 and 200 c.p., or the usual Edison-Swan lamps of 16 c.p. The rooms at present fitted are the drawing-room, dining-room, ladies' boudoir, gentlemen's room, recreation hall, billiard-room, offices, and lobbies. There are inside the main building over 150 lamps already wired, and these displace a rather larger number of gas jets. The work has been undertaken under the direction of Mr. C. H. Yeaman, electrical engineer, of 40, Prah-road, London, N, and Glasgow, for Dr. Meikle, managing-director of the establishment.

Cheltenham.—The Electric Lighting Committee at Cheltenham, on February 26th, submitted a report advocating the introduction of the electric light. Estimates had been invited for a combination of public and private lighting on the basis of 60 arcs of 1,200 c.p. (36 being required for street lighting), and 2,000 16-c.p. incandescents. From particulars and information thus received the committee arrive at the following conclusion: That motive power, generating machinery, circuit, lamps, and other plant sufficient for 60 arc lamps of 1,200 c.p. each, and 2,300 incandescent lamps of 16 c.p. each, including £1,800 estimated cost of site and buildings, can be erected for £11,900. This estimate is based on the circuit being partly underground and partly overhead. On the assumption that the whole of the arc lights will be alight on an average nine hours per night; and that the incandescent circuit has pressure on for 18 out of 24 hours, the incandescent lamps being supplied by meter, and alight on an average 1,500 hours each per annum, the annual cost of the production of this light, including repairs, maintenance, depreciation, and interest and repayment of capital, will be from £3,300 to £3,700 per annum. Assuming that 2,000 16-c.p. incandescent lamps yield an income of about ¼d. per lamp per hour, and 20 arc lamps are let out at £15 per annum each, your committee estimate that the cost of the 40 public arc lamps would be under £250 per annum. As will be seen, the number of lamps in the foregoing calculation is below the number which the plant is designed to supply, and as the demand for light increases the income will increase accordingly, which will allow of a proportionate extension of the public lighting at no greater cost. The committee estimate that 40 arc lights would render unnecessary 180 of the existing gas lamps, which at the present reduced price per lamp would cost about £450 per annum. A saving of £200 per annum would, therefore, be effected in the public lighting, while the power of the light would be many times greater. There are two sites belonging to the Corporation, either of which would be available for a station—namely, Barrett's mill, and the land purchased for the erection of the destructor. The latter has the advantage of access to the railway, thereby slightly reducing the cost of the coal, but the former is more central, and, on the whole, your committee recommend the adoption of that site, a course in which they are confirmed by the representatives of both the firms they have been in communication with. The committee having given an approximate estimate, ask to be allowed to proceed with the matter and procure tenders to be submitted to the Council. A meeting of the Council was held on Monday last, and Mr. Norman, in an able speech, a model in point of view of accuracy of statement and lucidity, pointed out the advantages of the scheme discussed, and the report in detail. The speeches of Messrs. Griffith and Lawrence supplemented this. An amendment to the adoption of the report was proposed, but the opponents were many of them in favour of the lighting, the opposition mainly arising from timidity as to the success of the scheme. The report was finally carried with four dissentients, amidst some applause, and tenders will be invited. As Cheltenham is the only town, except Bradford, where the Corporation is going to become vendors of electric energy, this decision is of very considerable importance.

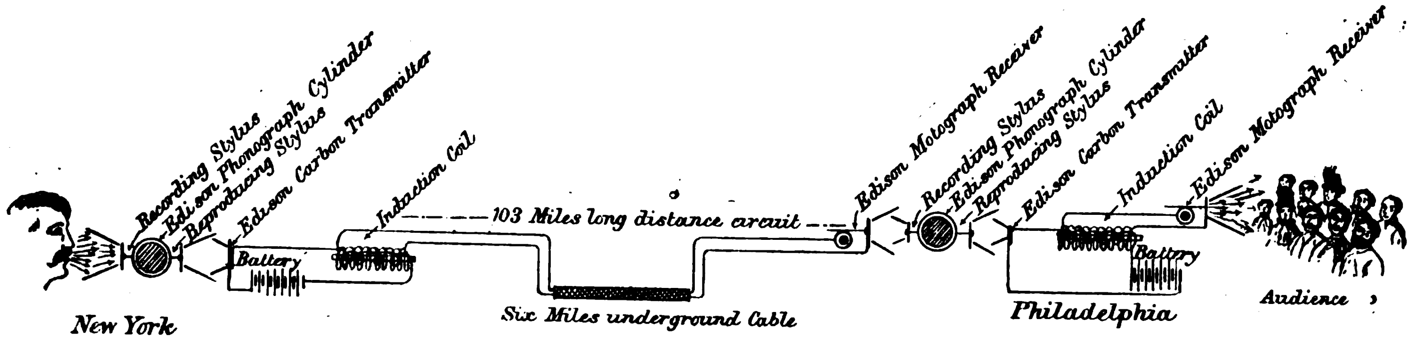
A PHONOGRAPHIC AND TELEPHONIC EXPERIMENT.

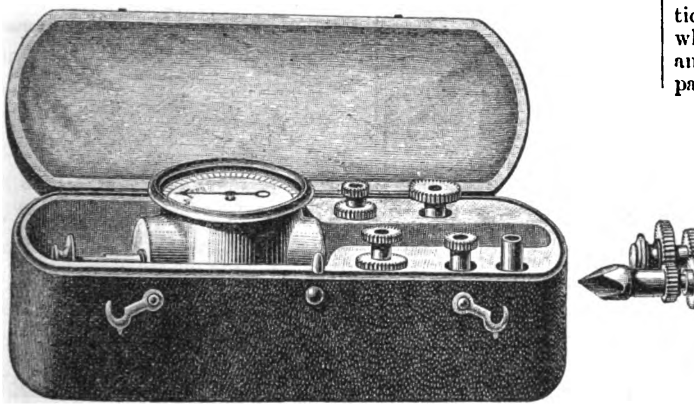
Mr. W. J. Hammer, a gentleman almost as well known on this side of the water as in America, recently gave a lecture upon "Edison and His Inventions" at the Franklin Institute, Philadelphia, in the course of which he carried out an extraordinary experiment illustrating phonographic and telephonic transmission between New York and Philadelphia. This experiment has been referred to and illustrated in various English papers, but in every case inaccurately. Some days ago we received from Mr. Hammer—who, by the bye, will soon be welcomed by his friends on this side, as he is coming to the Paris Exhibition —a description of the experiment, and from the drawings the illustration given herewith has been prepared. The illustration almost explains itself. It employed two Edison phonographs, two Edison carbon telephones, two Edison motograph receivers or loud-speaking telephones, two induction-coils, two sets of batteries, and 103 miles of long distance telephone wire—six miles of which was underground cable. These mediums included glass, iron, and mica diaphragms, composition of wax cylinder, of chalk cylinder, carbon buttons, steel stylus, palladium-faced pens, copper wire, and air. The experiment shows three of Edison's remarkable inventions working in juxtaposition—his carbon transmitter, his motograph receiver, and his phonograph. A successful experiment of so complicated a kind speaks volumes as to the excellence of these pieces of apparatus.



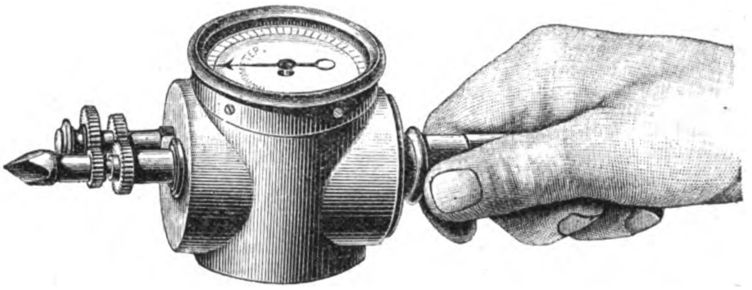
Phonographic and Telephonic Experiment.

POCKET TACHOMETER.

For all manner of electrical engineering, testing, and for laboratory work with dynamos and motors generally, the possession of a good and easily readable pocket speed indicator is a pressing necessity. There are several specimens of fairly practical speed-counters now in use, but, unfortunately, the "counting," with most of these has to be done by the observer, the instrument merely recording the number of revolutions on a dial of figures. For some work, such as the counting of the revolutions of engines, this kind of speed-register is specially required, but for experiments or tests where the speed of rotation is required, an instrument showing this by direct reading is greatly preferable. Instruments of this type, under the name of tachometers, constructed to indicate directly and continuously the precise speed of rotation, are now generally used in electric light installations connected permanently with the dynamos. Messrs. Schaeffer and Budenberg, makers of these tachometers, are now introducing a pocket tachometer of the same type, but very much smaller, which is intended to be used by hand. It is very light and portable, and the actual speed of revolving shafts, in revolutions per minute, is indicated upon a dial face with the same accuracy as the larger instruments.



Pocket Tachometer in Case.



Schaeffer and Budenberg's Pocket Tachometer.

The pocket tachometer is employed in the usual way, by holding it with a slight pressure of the hand against the end of the rotating shaft, so that the steel bit provided on the spindle end of the apparatus enters the centre mark of the shaft. The instrument will then indicate directly and continuously the precise speed of rotation of the shaft. The instrument is ordinarily divided up to 1,000 revolutions per minute.

For use with higher or lower speeds than those for which it is graduated, two sets of small toothed wheels are supplied, which can be quickly attached, and by this means the relative speed of the tachometer can be increased to double or reduced to one-half the ordinary indication, the speed of the shaft being then obtained by simple multiplication or division of the readings by two. The instrument, with its toothed wheels, is fitted, as shown, in a neat leather case, and should prove exceedingly useful to electrical engineers.

NATIONAL ELECTRIC LIGHT ASSOCIATION (AMERICA)—MEETING AT CHICAGO.

Our American contemporaries have had one of their periodical meetings, at which they have once more shown the intense practicality of their ideas. At these meetings—which savour somewhat of the character of the half-yearly meetings of the Iron and Steel Institute or the Institution of Mechanical Engineers—papers on practical subjects are read and discussed. Part of the proceedings is of interest only to electrical engineers in America; another part has a wider interest, and appeals to all in the profession whether practising in America or any other part of the world.

Instead of attempting to reproduce the papers and discussions, which other demands on our space forbids, we shall endeavour to give the gist of them, believing this will best meet the requirements of our readers. The abstract is made from the full and excellent reports of the *Electrical World* and the *Western Electrician.*

The PRESIDENT (Mr. S. A. Duncan), after referring briefly to the history of the organisation, suggested that the question of the day is the electrical distribution of power. The progress made during the year by the electrical industry was shown by the following table, the figures of which were analysed in reat detail:

—	Feb., 1888.	Aug., 1888.	Feb., 1889.	Feb., 1888, to Feb., 1889.
Central station and isolated plants ...	4,000	5,351	5,747	—
New central stations and isolated plants	—	1,351	716	2,067
Per cent. increase of central stations and isolated plants	—	32·3	13·5	50·1
Arc lamps	175,000	192,500	219,924	—
Increase of arc lamps.........	—	35,201	27,424	62,625
Per cent. increase of arc lamps	—	20·1	14·2	34·3
Incandescencelamps	1,750,000	2,142,440	2,504,490	—
Increase of incandescence lamps ...	—	392,944	361,546	754,490
Per cent. increase of incandescence lamps	—	32·3	16·7	49·0
Increase in capitalisation of electric light companies..	—	$42,210,100 Total.	$27,187,634	$69,397,744 Total.
Electric street railways in operation.	—	34	Inc. 19	53
Electric street railways being built..	—	83	Dec. 39	44
Electric street railways incorporated but not yet contracted for.........	—	39	Inc. 3	42
Electric cars in operation	—	223	,, 155	378
Electric cars under contract; roads not yet finished...	—	244	,, 185	329
Miles of single track in operation	—	138	,, 157·5	294·5
Miles of single track under contract, not yet in operation	—	189·5	,, 84·25	273·75

An exhibition of apparatus in connection with the meeting was referred to as an important feature, and attention was called to the papers to be read, and the satisfactory financial position of the association, which showed a balance to the good of over 2,500dols.

The first paper was the report of the Committee on "Patent Legislation," read by Mr. A. STEUART, which recommended the passage of the Bill to establish a Court of Patent Appeals.

The jurisdiction of the court as prescribed as defined in the Bill is as follows:

Section 14. The Court of Patent Appeals of the United States shall have appellate jurisdiction in the cases hereafter specially provided for without regard to the sum in controversy:

1. From the courts of the United States having original jurisdiction of cases touching patents, copyrights, trade marks, and labels, in all cases involving these subjects.

2. From the Commissioner of Patents in all cases touching the patentability of inventions, priority of invention among several claimants for patents upon the same invention, and in all cases of reissue and the judicial practice of the Patent Office; also all cases touching the registration of trade marks and labels and the rights of conflicting claimants therefore.

Section 15. From and after the passage of this Act there shall be no appeal from the Circuit Courts of the United States or any territorial or district court or courts of the district of Columbia, in cases touching patents, trade marks, copyrights, or labels to the Supreme Court of the United States directly, but all such cases formerly appealable to the Supreme Court shall be heard on appeal by the Court of Patent Appeals.

Section 16. There shall be a right of appeal from the Court of Patent Appeals to the Supreme Court of the United States in all cases, regardless of the amount in controversy, subject to the same regulations, however, as now exist with regard to appeals to the Supreme Court in causes of Admiralty and maritime jurisdiction, and to such further regulations as the Supreme Court of the United States may make.

Section 17. All cases touching patents, trade marks, copyrights, or labels now pending before the Supreme Court of the United States awaiting trial shall be transferred to and heard by the Court of Patent Appeals.

Mr. E. T. LYNCH read the report of the Committee on "Underground Conduits and Conductors." The report was based on 120 answers received by the committee to the following questions:

1. Have you ever placed underground any electric light conductors carrying currents at a potential of 1,000 volts, or over?
2. If so, state the number of experiments, giving the date of each?
3. What was the length of each individual conductor laid underground?
4. What was the voltage on each conductor?
5. What was the current, in amperes, carried by each conductor?
6. What make and style of dynamo supplied the current on each of these conductors?
7. Were these conductors single, or grouped in cables?
8. How many conductors to the cable?
9. What was the size of the conductors used? (In answering this question give the number and gauge.)
10. What was the thickness of the insulation?
11. Who was the maker of the cable?
12. Were the cables laid in any form of conduit?
13. If so, what kind of conduit was used?
14. Describe the manner in which the cables were laid in the conduit; whether drawn in, built in, or otherwise?
15. If the cables were laid directly in the ground, describe the method of laying them.
16. Was there more than one duct in the conduit?
17. If there were other ducts, what was in them?
18. Did you have exclusive control of the conduit?
19. What was the total duration of your experiments?
20. Did the cables work satisfactorily during the entire time of your experiments?
21. If not, how long did they work satisfactorily?
22. If the cables failed to work satisfactorily, to which of the following causes do you attribute the difficulty? Please answer as fully as possible:

a. Defective insulation?
b. Defects in joints?
c. Defects in making connections from cables to lamps?

First: The writer has used the underground conductors for three years. Has used wire of three of the most prominent manufacturers. Has discarded two, and is now using the third.

The cables were carried in a cement pipe, and manholes were placed at every 250ft. Cables had been drawn into the conduits, and as a method of facilitating their drawing in, pulverised soapstone had been used for the purpose of avoiding abrasion.

Only one wire placed in each pipe.

He states that the wires have not worked satisfactorily, and that he has been compelled to shut down many times; that they are now running fairly well; but he is obliged to keep them under constant supervision and repair.

He accounts for most of the trouble that he has experienced by defective insulation, defective mechanical construction, and by deterioration in the insulation in the wires, having had no serious trouble with the style of conduits that he has used.

In answer to the question regarding the practicability of placing his conductors underground, he states: "We are operating some eight miles of underground wire; we wish there were less, and certainly are not anxious for more."

In answer to the question regarding the difficulties and objections to underground wiring, and whether he considers them commercial, electrical, or mechanical, he states:

Electrical.—There is no cable that will last with a current from a 50-light dynamo. Commercial.—Owing to the large cost of construction, and expense of maintenance, and great possibility of breaks. There is consequently poor service and dissatisfaction. He has exclusive control of his conduit.

Second: The writer has made many experiments, in which he has used lengths of cable varying from 200ft. to two miles in length, manufactured by most of the prominent wiring companies. Cables have been laid in and drawn in his own conduits, conduits constructed both of wood and iron. The tests have usually been of short duration, and have been suspended in each case after a failure of the cable to work satisfactorily. The cause of the failure has been mainly defective insulation. Defective mechanical construction, defects in laying, defective conduits, injury to cables in laying or defective joints, have caused very little trouble, the main cause of trouble being in defective insulation and deterioration owing to the presence of gas, water, and steam.

His opinion, based upon the results brought out by the many tests that he has made, is that he does not consider it practical at the present time to place conductors underground, the absence of insulation that would stand being the principal reason. If ever that question is settled the cost would, in his estimation, make it commercially impracticable. In only one instance he had the exclusive control of the conduit.

Third: The company represented by the writer had four circuits underground for about one year. One style of cable only, manufactured by a prominent manufacturer, was alone used. The wire was drawn into a composition conduit, which had manholes at the corners.

Quite an amount of trouble was caused in the start off by difficulty caused by abrasion to cable in drawing the wire into the conduit. The experiments were continued for one year. They caused a great deal of trouble with the lighting contracts, and at the end of that time were abandoned. He considers his chief troubles to be defective conduits, water in the conduits, and deterioration of the cables; also trouble in defective insulation, defects in the joints and trouble in making connections through iron pipes from the conduit to the surface.

Digitized by Google

His opinion, based upon the results of the tests that he has made, is: "That he does not consider it practicable to place his wires underground," and he states, "I do not know of any system that has yet proved satisfactory." And further states: "I know of no system to-day which, even at any expense, has proved satisfactory, except a system of subways built large enough for men to walk through their entire length."

In answer to the difficulties of placing wires underground, he states that he considers the difficulties to be commercial, electrical and mechanical in perfection, and still not be so expensive (in the end) as to make the commercial objection insurmountable. "We are all in the business simply to make money, and the commercial objection must be met just as much as any other." He did not have exclusive control of the conduit. The ordinance passed by the Common Council in his city in 1886 stated "that their committee had examined the subject, and found the putting of all electrical wires underground feasible, and ordered all wires within a few months, and those outside of this district, underground within one year." He has been brought before the court a number of times on complaint of the City Attorney, but nothing yet has been done in the matter.

Fourth: The writer has made two experiments during the last summer, one of which was a failure, and the other a partial success, though the duration of the second test and the position it occupied in the circuit was such as to give little importance to the result. The wires were pulled into a wooden conduit, there being two ducts in each conduit. Cables did not work satisfactorily. He states that the failure is due entirely to defective insulation.

In answer to the question if he considers it practicable to place his conductors underground, he replies, "We do not, with any system known at present."

In answer to the last question, concerning the difficulties and objections to placing wires underground, he states: "The difficulty is particularly commercial, though I have seen no system which I think will properly insulate the conductors."

Fifth: The writer has placed two circuits underground, about the first of the present year. The cables used are those manufactured by six of the most prominent companies. They have been drawn into an asphalte conduit, twelve ducts in each conduit. The duration of his experiment has only been about a month and a half, and he states that it is too early to tell what will be considered the result of the experiment.

In answer to the question if it would be considered practicable to place the wires underground, he states: "Have seen nothing yet that will answer."

In answer to the question regarding his opinion concerning difficulties and objections to going underground, he replies: "Chiefly commercial, partly electrical and partly mechanical." He has exclusive control over his own style of conduit.

Sixth: The writer has had wires in the conduits for about five years. The mains were carried through the streets in a composite system of conduits. The connections are made from the system to the cellars through iron pipes, and the wires are conveyed then through cellars, connection being made from the cellars to the houses. These cellars run completely around the block, and permit of access to them for the purpose of repairing or making connections to wires.

He has used three different kinds of wires in the conduits, the cables now in use having been in position for about thirteen months; although he has had trouble with them, he claims that satisfactory service can be maintained in his particular locality, and he considers the question of the distribution of power and light an exceedingly simple one in his city, which is probably the only city that is so fortunately situated.

He has, in all, about 32 circuits. He states that he is on the right track regarding the placing of wires underground, and that the system such as he operates will run satisfactorily. The cables that he is using are guaranteed for three years. The trouble that he had with his first wires was mainly due, as far as he can ascertain, to the fact that the insulation surrounding the wires was not of sufficient thickness, and the main conduits themselves were not dry. He controls his own conduits exclusively.

Seventh: The writer has made some practical experiments and tests with cables under water; these were manufactured by two of the most prominent companies. The cables did not, however, work satisfactorily, lasting, as they did, from three months to one and a half years. He lays the cause of failure to the effect of water upon the cable, and the deterioration in the insulation of the wire. His opinion, based upon the tests he has made, is that he does not consider it practicable to place his conductors underground. Considers that the difficulties are both electrical, mechanical, and commercial. Had exclusive control over such conduits as he used.

In summarising the results of the experiments in these cities, in one case only did the electric light company place its wires underground willingly. In all others they were forced to do so by the local authorities.

In only one instance have the experiments or practical workings proved satisfactory. The only other case that they did not report adversely, being where the wires had only been in operation about 40 days. The average voltage that they have used on all the circuits tested was 1,893 volts; the current was 10 amperes. The average thickness of insulation over wires was $\frac{5}{32}$ of an inch, and the average length of cables tested in each case was about 4,600ft.

In considering the second class of answers, namely, those who have not yet made any extended practical test, their answers have been directed mainly to the last four questions, the first two of which relate to action by the municipal authorities, and the last two consider the practicability and the difficulties of placing wires underground. In very few of these cities have the municipal authorities yet taken any steps towards action upon the matter, having been delayed in awaiting the solution of the underground question in other cities.

In answer to the question asking them if they considered it practical to place their conductors underground, 104 have replied that their opinions based upon tests that they have seen and such information as they have been able to obtain, both in this country and abroad, is "that it has not been practical to place the wires conveying high-tension electric arc light currents underground."

Two have answered that they considered it practical to do so, but state that at the present time they have no wires underground.

In answer to the question which asks their opinion regarding the greatest difficulties to be met with in considering the placing and operating of underground wires, they all unite in the opinion that "the difficulties are both mechanical, electrical, and commercial." They consider that the question of obtaining a satisfactory conduit has not been properly solved; and that even if that should be solved in the future, that we cannot even at this time obtain a satisfactory insulation for the wires that will not deteriorate within a few years, and become perfectly useless as an insulator when subjected to the action of steam, water, and gas. The great difficulty of making connections for buildings and lamps, and the absence of any satisfactory system of subsidiary conduits, is considered by all as a bar to successful operation, as the difficulty of drawing in cables without abrasion to the insulating covering, even with the most careful handling, is very great.

The commercial objection is considered a very great one, as not only is the first cost about eight times heavier than that of an overhead system, but the repairs to the cables due to the deterioration of the insulation and other defects caused by mechanical or electrical deficiences would be very much heavier than the expense of operating and maintaining overhead systems, and that the prices at which they are now furnishing the electric light would have to be very materially increased to meet these extra and very heavy expenses. A system of tunnels through all the principal streets is considered to afford the only means for the solution of this problem. . . . .

Other companies reply that the wiring of their system that has been used for underground purposes has been for potentials under 1,000 volts, and that they have met with entire success with potentials of a system with 1,000 volts. And they do not anticipate in the future that they will have any trouble in furnishing wire to meet the requirements of the electric lighting companies, but at the present time they have not yet done so. They unite in stating that they think that the question of the insulation of high voltage of currents should be solved by the using of good durable thick insulation. Their experience in conduits has been that they do not want creosoted wood, but would prefer to have their wires buried in the ground or under water, and would recommend at the present time that single conductors should be used. They seem to be about evenly divided on the question as to whether lead-covered cables should be used for underground purposes.

In the discussion, Prof. BARRETT, of Chicago, had used underground conduits for six years; result satisfactory. Mr. W. H. JOHNSTONE referred to its use in Philadelphia "with perfect and uniform success," to conduits now being used in New York and said "Mr. Lynch would have to reverse that report in a very short time." Mr. ECCLESINE believed that "they will be compelled to go underground by public opinion." Mr. T. C. SMITH argued that by overhead wires, if properly carried out, was the best way of distributing power. Mr. LOCKWOOD had tried underground cables with current of from 1,800 to 2,000 volts and had given them up. Mr. B. E. SUNNY said:

We put through our cables all the way from 2,000 to 3,000 volts, and sometimes go higher. Of course, I cannot say how long the cables that we have now, that have been in use for just about a year, and have only given us four cases of trouble—I cannot say how long they are going to last, or how long they are going to furnish that satisfactory service, but just at this time they seem to be in first-class condition; they are doing all for us that we expected they would, and we are perfectly satisfied with them. Scientifically, it is all right. The only objection we have is a financial one. I made up some figures a few days ago, and I find that it is costing us the difference to furnish this service from underground conductors as compared with aerial conductors about as follows: Circuit reconstruction and maintenance of conduit amounted for three months to 9,610.95dols. That was for 1,194 lamps for eight hours a day for 90 days, or 959,680 lamp-hours. You see the cost of underground conductors is a trifle more than 1 cent. per lamp-hour over and above what it would cost on an aerial conductor. Now, you will say if we had nothing but aerial conductors we would still have the item of circuit reconstruction. This is very true, but I have left out the question of underground conductors so far as the repairs on electrical machinery are concerned. It is no question in our minds at all but that we are put to 200dols. or 300dols. expense every month on account of repairs to the electrical apparatus that are made necessary owing to our underground cable, so that I think it is perfectly right to say that if our wires were on poles in the streets the troubles I have enumerated would be eliminated. We figured, therefore, that from a scientific and practical standpoint underground cables are all right. From a financial standpoint they are costing us one cent. per lamp-hour here more than aerial conductors. The conduit rent is 1,000dols. per year per duct. The duct will hold three electric light cables; so that the rent per mile for each conductor is about 333dols. 33 cents. The item of circuit reconstruction—9,610dols.—included going over the joints in manholes, pulling out some sections of cable, and replacing, taking out, and renewing some wires under sidewalk; it included everything that we did with the plant that we could not charge to construction.

Mr. E. A. SPERRY also had satisfactory experience with an underground system current at 1,800 volts. Other speakers prophesied failure where conduits were used. Letters were

Digitized by Google

read from Mr. W. Hochhausen and Prof. Elihu Thompson. Both lacked decision: it may or it may not—wait a little, get more experience, and then—business expediency, go gently—and so on. Result of discussion: everybody started with his own opinion, and kept it.

ARC LAMPS AND THEIR MECHANISM.*

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

An arc lamp being an apparatus for transforming the electric energy supplied to it through the conducting wires into heat and light, it obviously cannot be expected to give a steady illumination unless it can be so arranged and operated that, in the first place, the rate at which it appropriates and transforms the electric energy is constant, and that, in the second place, the circumstances attending this transformation (in respect of the triple relation between the quantity of heat evolved, the degree of temperature, and the emissivity of the incandescent surface) also remain constant. The first of these two provisos relates to the operation of the system of lamps and dynamos (or other means of electric supply) acting conjointly; the second of them relates solely to the quality of the carbon pencils used as electrodes.

As the latter is a simple matter, it may be disposed of first. Suppose the pencils to be composed of a homogeneous carbon, the physical properties of which, such as hardness, specific thermal capacity, conductivity for electricity, conductivity for heat, emissivity, etc., are constant; also that they are cylindrical and of given diameter. Then it follows that if energy is being expended at a uniform rate in heating the tips of a pencil it will be maintained at a uniform temperature, and the amount of light emitted per square millimetre of the surface will be constant, and, as the section is constant, the rate of consumption constant, and the pencil homogeneous, the form once acquired by the incandescent tip (whether positive crater or negative peak) will remain constant. It may be remarked, in passing, that the researches of Captain Abney have shown that the white light of the incandescent carbon surface of the crater at the positive pole of the arc is always of precisely the same composition in respect of the relative proportions of waves of different colours. This most important observation indicates beyond doubt that the temperature of the actual light-emitting surface is always the same. Indeed, this ought to be the case if the latent heat of vapourisation of carbon be a positive quantity. When the surface attains this temperature, a volatilisation begins; and when so begun the temperature cannot rise further, any more than ice can be raised above its temperature of fusion. The limiting temperature of the voltaic arc is the temperature of volatilisation of the material of the electrodes. This is, in itself, a reason why the introduction of all known foreign substances whatsoever into the carbon pencils of the arc is found to lower its intrinsic brilliancy; for all known elements have a lower temperature of volatilisation, and all compounds are dissociated at arc temperatures.

If, then, we may assume homogeneity of the carbons to be used, the steadiness of the arc light will depend solely upon the maintenance of a steady rate of appropriating and transforming electric energy. How a want of homogeneity may be compensated for in the actual working of the lamp is a point reserved for consideration later.

The rate at which electric energy is appropriated from the wires, and transformed in the lamp into heat and light, always depends both upon the construction of the lamp and upon the conditions imposed upon the system of electric supply. This is a mere consequence of the fact, well known to every electric engineer, that the amount of electric energy per second appropriated by any electric device, motor, or accumulator, is itself the product of two quantities—the current and the pressure (or potential) at which the current is supplied. To put the matter in electrician's language, the number of *watts* of electric energy per second appropriated by the lamp† is equal to the number of *amperes* that flow through it multiplied by the number of *volts* that may be applied as a difference of potentials between its two terminals. To keep constant the *product* of the amperes and the volts is the practical problem which the mechanism of the arc lamp must be designed to solve.

A point of much theoretical interest, and in reality of great practical importance, is the fact, long disputed, now established beyond question, that the arc itself does not act simply as an added resistance in the path of the current, but exercises also a counter E.M.F., and tends to set up an opposing current. The apparent resistance of the arc resembles that of an electrolytic cell, or that of an electric motor when running, or that of a thermopile when a current from an external source is passed through it. The current which flows through the arc arouses, by a species of polarisation, an opposing E.M.F. The simplest fact in proof of this is that, unlike any ordinary conductor, the apparent resistance of the arc is not proportional to its length. The apparent resistance of an arc two millimetres in length between the carbon tips is not double that of an arc one millimetre in length, nor anything near double. The fairest way to investigate the matter is to make a series of experiments with arcs of different lengths, the current being independently so regulated as to be maintained of the same strength in each case. There appears to be a true resistence proportional to the length, and a back E.M.F., which in steady arcs, and with currents of from seven to fifteen amperes, appears to be about 38 to 39 volts. When the arc hisses, as often happens if the length of it be very short, the back E.M.F. fluctuates very much, but always drops to something under 20 volts. Except in the case of constant-current circuits, this causes a sudden increase of current when the lamp begins to hiss, and it may be noticed that the light, though unsteady during hissing, is brighter at the negative pole of the arc.

Hitherto all guesses as to the cause of this counter E.M.F. have been very vague, not to say wild. To account for 39 volts of polarisation on any hypothesis that it is due to electrolytic or thermo-electric action, is to suggest causes which are, to say the least, wholly inadequate. The explanation which for the past two years I have been in the habit of suggesting to my students, and which has not been otherwise published hitherto, is as follows: Every reversible phenomenon which the current can itself produce, and which requires an expenditure of energy for its production, necessarily implies the exhibition of a counter E.M.F. One has only to look at the cases of the reversible chemical action in a cell, of the reversible magneto-mechanical action of a motor, the reversible heating effects of a thermo-electric junction, to comprehend this. Now the phenomenon of volatilisation is a reversible one: give to the solid carbon at its volatilisation temperature the necessary latent heat, it is changed to vapour; take from the vapour its latent heat, it condenses back to solid carbon. The arc under normal circumstances is the seat of an actual evaporation of carbon at the positive pole, as well as of a combustion at both poles. So far as any data exist, it appears that the excess of carbon consumed at the positive pole by an ordinary continuous current, is about 0·5 grammes per ampere-hour. If we knew the latent heat of volatilisation of carbon per gramme we could calculate *à priori* the necessary minimum E.M.F. at the positive pole, which would obviously represent the counter E.M.F. so far as it is situated at that point. With long arcs the excess of consumption of the positive pencil over that of the negative is both less and more regular than that which occurs with short arcs. With short arcs three other phenomena occur which are important in this connection. Firstly, the short arc is liable to whistle or hiss, giving evidence of instability; secondly, it frequently gives rise to "mushrooms," or irregular growths of carbon upon the apex of the negative pencil; thirdly, when it hisses, the counter E.M.F. becomes very unsteady, but appears to have an average value about half that of the steady long arc. It is worth while to throw out the suggestion, that the condensation of carbon at the negative pole, in the short arc, is accountable for the change in E.M.F., and for the instability which manifests itself by the hissing sound.

Passing from these conjectures to the construction of lamps for the production of light by the arc, we are now prepared to lay down the points which must be provided for in every arc lamp. It must be emphatically pointed out at the outset that, as the performance of a lamp depends upon the conditions under which it is supplied with electric energy by the circuit, the design of the lamp necessarily also depends on those conditions. In the present state of the art of electric distribution we may classify the conditions of electric supply under the following heads:

I.—CONTINUOUS SUPPLY AT CONSTANT POTENTIAL.

In this case the arc lamps are arranged either simply all in parallel

* Paper read before the Society of Arts, March 6th.

† Strictly speaking, the actual number of *watts* utilised in the arc is somewhat less than the whole number received from the supply, as a portion of the energy is expended in passing the current through the regulating coils, and another portion is lost in consequence of the resistance offered by the pencils of carbon themselves, and is merely expended in warming them. We may calculate the former loss as follows: Let E represent the whole number of volts from terminal to terminal, and let i represent the whole current supplied, then the whole number of watts supplied is Ei. Let the *ohms* of resistance of the regulating coils in the main circuit be called a, and that of the shunt-coils be called b, that of the carbon pencils themselves c, and that of the resistance-coils sometimes used in the main circuit to steady the arc, r. Also, in the case where the lamp has a shunt circuit, let the portion of i which passes through the carbons be called i_1, and that which goes through the shunt, i_2; so that $i_1 + i_2 = i$. The losses are then as follows:

$$ai_1^2 = \text{watts lost in main circuit coil;}$$
$$bi_2^2 = E^2 \div b = \text{watts lost in shunt-coil;}$$
$$ci_1^2 = \text{watts lost in warming carbon pencil;}$$
$$ri^2 = \text{watts lost in the resistance coil.}$$

The resistance of carbon pencils is usually small, and may be materially reduced by a thin coating of copper. The carbons used in commerce (11 to 15 millimetres in diameter) vary from about 1·15 to 0·2 ohms per foot, if plain, and from 0·001 to 0·09 if coppered. Cored carbons have a higher resistance than uncored. Carbons cut from solid gas-coke have from five to twenty times as much resistance as those made by the usual modern processes. When lamps are run in series, the resistance offered by the pencils is of more importance; for example, a set of 50 lamps newly trimmed with long carbons may offer 25 ohms more resistance than when all the carbons have burned down short. The resistance, a, of the regulating coils that are in the main circuit differs in different lamps, but may be taken at from 0·05 to 0·2 ohms. The resistance, b, of the shunt-coils is seldom less than 200 ohms, and may be as much as from 400 to 500 ohms. Of the volts, E, applied to the lamp only a part is utilised, the lost volts being accounted for by the resistances in the path of the current. If these are deducted from the applied E.M.F., there will remain a certain number of volts, which we may call e, which are available as a useful difference of potential at the arc itself. To measure e directly, one has only to apply a voltmeter, making the contacts of its two leading wires to the two carbons at points respectively just above and just below the incandescent tips. The watts actually utilised in the arc are then calculated as the product ei_1. As shown above, e is less than E, and, indeed, may be considerably less, the lost volts depending upon the resistances introduced, and on the current flowing through them. If E is constant, e will not necessarily be so, but will be very nearly if i is also constant. Also i_1 is less than i in all lamps that have a shunt regulating coil, but is not usually more than from 3 to 5 per cent. less than i, so that in the cases where i is kept constant, i_1 will be nearly so also.

Digitized by Google

or in parallels containing two in series; the currents being divided by mains and branches to the lamps. At least 55 volts should be allowed between the mains for single arcs. Practice shows that arc lamps in parallel burn more steadily if a resistance wire of ·25 to 1·0 ohm be included in the lamp circuit. Taking the back E.M.F. of a steady arc at 39 volts, it is obvious that the excess of the volts at the mains over this represents the volts used in driving the current through the actual resistance in the main circuit of the lamp. This resistance consists of four parts—the true resistance of the arc itself, which may vary from $\frac{1}{15}$ to $\frac{1}{2}$ ohm; the resistance of the carbon pencils, which averages about 0·15 ohm per foot per plain carbons; the resistance of the main-circuit coils, which varies in different lamps from 0·05 to 0·2 ohm; and the resistance of the wire introduced for steadying the lamp. In a 10-ampere lamp, working at 55 volts at the mains, 16 volts remain, after deducting 39 for the back E.M.F., and these 16 are approximately distributed as follows: two volts in the arc itself, three volts in the carbons (say 2ft. long in the total), one volt in the main coil, and 10 volts in the steadying resistance.

II.—Continuous Supply with Constant Current.

In this case the arc lamps are arranged in series, the whole of the current going from one lamp to the next, and returning to the dynamo after having traversed successively all the lamps. This is *par excellence* the arc light system of distribution, the parallel system at constant potential requiring heavier mains. As the lamps arranged in series tend to steady one another, it is not necessary to allow more than 45 to 50 volts per lamp, including the ordinary lengths of cable from lamp to lamp. From 5 to 10 amperes is the usual current for arc lamps in series.

III.—Alternating Supply at Constant Potential.

In this case also, the lamps are usually arranged as in the first case, the only difference being in certain structural details, such as lamination of iron cores.

IV.—Alternating Supply with Constant Current.

This case can hardly be said to be practical, though alternate current dynamos, capable of supplying six or eight lamps in series, have been constructed in past years.

The supply systems, whether continuous or alternating, must be assumed, for the purpose of this paper, to perform efficiently what they profess—namely, to maintain constant one of the two factors of the electric power which they supply to the distributing system. In each case it remains for the mechanism of the lamp to effect such adjustment as will maintain constant the other factor of the product. If the condition of supply is "at constant potential," then it is for the lamp itself so to adjust its carbons as to keep the current through the arc constant. If the condition of supply is "with constant current," then the lamp must adjust its carbons to maintain between them the requisite potential. Hence the differences which are necessary in construction between those lamps which are to work "at constant potential" (in parallel) and those which are to work with constant current (in series). These differences, as will now be shown, chiefly affect the "feeding" mechanisms of the lamp.

In discussing the necessary mechanisms of arc lamps, no further reference will be made to lamps of the Jablochkoff candle type, nor to those with abutment blocks of marble ("Sun" lamp, etc.), nor to the so-called incandescence arc ("semi-incandescent") lamps, nor to those with curved carbons (Heinrichs's type), nor yet to those horizontal carbons (De Mersanne's, Solignac's, etc.).

Necessary Mechanism of Arc Lamps.

[A.] *Driving Power.*—In every lamp some means or mechanism is required to propel the carbons towards one another as they burn away, gravity being by far the most common agency for doing this.

[B.] *Striking Mechanism.*—In every arc lamp it is requisite to provide a mechanism for bringing the tips of the carbon pencils into contact, and then parting them asunder to the requisite distance across which the arc or flame plays. If, as in most lamps, the carbons are in contact when the lamp is out of action, then a mechanism is required simply to part them as soon as the current is turned on. The operation of producing the arc by parting the carbons is known as "striking" the arc. The mechanism must be automatic, so as to come into action not only when the current is first turned on, but at any subsequent time if from any cause the arc fails. An adjustment, *b*, of the striking mechanism is also usually added to permit of regulation in the length of the stroke or initial distance between the poles.

[C.] *Feeding Mechanism.*—As the carbons burn away, one or both of them must be propelled forward to maintain the arc at its proper size. This action is called "feeding" the arc. This action ought to take place by small and imperceptible amounts, and as the rate of consumption of the carbons is continually varying, even with carbons of the best modern manufacture, the lamp must itself regulate the rate at which the pencils are propelled forward in automatic correspondence with the consumption for the time being. Further, since the presence of soft and more readily volatilised portions in the pencils seems to be unavoidable, provision ought to be made so that, whenever the pencil burns down to such a portion, causing a sudden increase in the volume of the flame or arc—technically called a "blower"—the mechanism of the lamp ought at once automatically to draw apart the pencils to a slightly greater distance. A lamp which has a *retractile* motion in either its feeding or its striking mechanism is superior to one that has not, as it can be used with cheaper and less pure brands of carbon. An adjustment, *c*, for regulating the frequency or range of the feeding movements is usual.

[D.] *Replacement Mechanism.*—When the pair of carbon pencils has burned away, the lamp trimmer has to replace the stumps by a new pair of long carbons. In order to admit these, the carbon-holders must be pushed apart to their widest extent. Special mechanical devices for allowing this motion to occur have to be provided in some forms of lamp, whilst other forms need no special device.

[E.] *Moderating Mechanism.*—To prevent the carbon from making too sudden motions, it is usual to add a moderating device, such as a dash-pot, or, in the case of those lamps in which there is a train of wheels, a fan or a governor.

So far, the devices enumerated have been such as are common to all classes of lamps. Those which follow are only required in particular types of lamps.

[F.] *Focussing Mechanism.*—In all those cases where it is desired that the luminous points should occupy a fixed position in space, some additional mechanism is necessary to make the arc lamp keep its focus. In lamps designed for the mere lighting of area, this is not important, and in the vast majority of these the upper carbon descends whilst the lower carbon (the negative) is fixed: the luminous point slowly shifting downwards as the carbon consumes. All devices for causing the carbons to move forward at such relative rates as to keep an approximately fixed position for the arc will be discussed, together with their methods of adjustment, *f*, under the heading of focussing mechanism.

[G.] *Change over Mechanism.*—Lamps that must run for many hours continuously must be supplied with two pairs of pencils, because it is neither practicable nor advisable to use pencils of extreme length. In the double lamps it is appropriate to provide such arrangements as shall cause one pair of pencils to come into operation first, and when these are consumed away, shall change-over the action, either by electical or by mechanical devices, so that the second pair of pencils shall come into operation.

[H.] *Cut-out Mechanism.*—Lamps intended for series working must be provided with some contrivance to prevent the extinction of the whole series when from any cause there is a failure of the light in any one lamp. The usual device is a sort of automatic relay arranged in connection with each lamp, to come into operation in the event of its failure, the operation of the device being (1) to cut the faulty lamp out of circuit by simply short-circuiting it, or (2) to substitute for it a wire of suitable resistance, or (3) to replace it by an auxiliary lamp. The device for performing either of the two former operations is technically known as a "cut-out."

Supplementary Contrivances.

In addition to the eight distinct species of contrivances above enumerated, there are numerous details which might be further classified; such, for example, as devices for *clamping* the carbon pencils to their respective holders in true allignment; devices for raising and lowering the lamps. For these, however, there is no space. Neither is it possible to enumerate the devices which have been suggested (Staite, Siemens, Brockie, Andrews, Crompton, Swinburne, and others) for *compensating*, in lamps whose action depends on the weight of the descending carbon pencil and its holder, for the diminution of pull as the pencil is consumed.

Schedule of Mechanisms.

A schedule embracing the eight heads above enumerated, if supplemented by statements of the gauges and resistances of the wires used in the windings of the coils, affords a systematic and very convenient method of tabulating the facts concerning the construction of any arc lamp. An example of such schedule, filled up with the data of one arc lamp of recent pattern, is given at the end of this paper.

Electromagnets for Arc Lamps.

As the electromagnet plays so essential a part in the striking, feeding, and cut-out mechanisms of lamps, a short digression upon the particular forms of electromagnets appropriate to arc lamps is not out of place. The ordinary treatises on electricity have little to tell about the special properties of different forms of electromagnet; indeed, this all-important organ in modern electrical engineering has received very inadequate attention from writers on electricity. It is a familiar fact that the attraction of a horseshoe-shaped magnet, whether of steel or iron, varies very greatly with the position of the iron armature, being great at small distances, but very rapidly falling away as the intervening space is increased. To devise a form of electromagnet whose attractive power shall be exerted over a fairly long range was at one time one of the practical problems of electricians, and it has been solved in various ways. The attraction which a solenoid, or tubular coil, exerts, when transversed by a current, upon an iron core introduced within its aperture, is not, in any position of the core, nearly as great as that exercised by an electromagnet of horseshoe type, constructed of equal amounts of metal, and energised by an equal current. On the other hand, the feebler pull of the solenoid upon its core is exerted through a very extended range. And by making the core of conical form, or by winding the coils of the solenoid in a conical fashion, it is possible still more completely to equalise the pull over a long range. Solenoids with cores are used in several well-known types of lamps in which a long travel is required. On the other hand, since the operation of striking the arc requires a short motion not exceeding one-twelfth of an inch, or two millimetres, in all those types of lamp in which a special electromagnet is used simply to strike the arc, a form of electromagnet is required which will exert a powerful pull over a short range. Further, for working certain clutch mechanisms and the like, it is desirable that a form of electromagnet should be found which, whilst having a travel of, say, one inch, should exert throughout the whole of that range a fairly strong pull, increasing of course toward the end.

(To be Continued).

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence ; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices :
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

'SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d.	...	17s. 4d.
Other Places..................	4s. 10d.	...	9s. 8d.	...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. and II., new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of Mr. E. Graves, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. Wollaston, M.D., F.R.S., *and* Sir Humphry Davy, F.R.S. *The portraits of* Prof. D. E. Hughes, F.R.S., *and of* Dr. J. Hopkinson, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

FASHION IN ELECTRIC LIGHTING.

The paper of Mr. Kapp before the Institution of Civil Engineers and the discussion thereon seems to give an opportunity for reflection as to thoughtlessly following the prevailing fashion which, for the moment, finds favour with electric light engineers. The two great electric lighting systems are respectively the direct and the alternate current systems. Each has its advantages and its disadvantages from the lighting contractor's point of view. With every desire to find favour with those actively engaged in electrical matters, we are compelled occasionally to point out that their education is extremely defective, for very few are mechanical engineers. The majority have no experience of mechanical engineering, and because they can gabble over some formulæ, and drive the real engineers into a corner by quoting Ohm's or some other law, they imagine that what they do is and must be right. The rising and purely scholastic electrician is a poor animal—too conceited to understand his weakness, and too ignorant to do aught but disagree with what anyone else does or proposes. He is a shade worse than the pure mathematician, who cannot act till some practical man puts the data into his hands, and then his soul is in arms to show that some torm having an infinitesimal bearing upon practical work is shelved by the rough-and-ready workers in the shops.

Let us try and see ourselves as others see us, and ruminate how far the strictures made are warranted by the facts of the case. The mechanical engineer believes in machinery, well designed and well made for the purpose of doing the work it is expected to do. But he also expects that when his machinery is constructed it is going to be worked and not lie idle. He laughs at breakdowns. He does not duplicate his mill engines because they may perhaps break down. He drives his ships through nine or ten thousand miles of water and expects his engines to work smoothly and comfortably. He is prepared to produce engines that shall stand the wear and tear of central station work, and not make much fuss about it. He goes on pumping day and night, week in and week out, and thinks very little about the matter. Thus he looks upon the electrical engineer, who makes dynamos that are expected "more or less" to break down, as a man who does not know his business. From the engineer's point of view, there is no reason why a well-designed and well-constructed dynamo should break down. Overheating, breaking down your insulation, etc., are "bugs" that ought not to be possible. Overheating means bad designing or bad construction, too little copper, metal possibly where it ought not to be, and no metal where it ought to be. Breaking down insulation is primarily due to similar causes, and to dust and dirt or other foreign matter getting where it ought not to be—which again comes to bad design.

Digitized by Google

This is a small part of what mechanical engineers tell us.

Come we now to a central station designed upon the alternate current system. Our real engineer asks if all that machinery is put down just to be able to do the maximum work one or two hours out of twenty-four, and to lie idle eleven-twelfths of its time. Prudence, and a dislike to be laughed at, inclines us to prevaricate, but mendacity does not pay with these gentlemen, so reluctantly we acknowledge the fact to be as stated. We have dinned into our ears once more the rule that guides the engineer. Work your machinery all you can, don't let it lie idle. Work and make money, otherwise pay heavily for idle plant. The commercial man listens, thinks, and says, Why, only about one-fifth of your power is pretty constantly at work, and really has to earn your dividends—if any are earned—while four-fifths of your plant are idle four-fifths of the time. There ought to be some wonderful compensating advantages for all this; and so there are, says the electrical engineer. By this device we save largely in our mains, being able to work at a higher pressure, transforming down at the houses to a workable or rather to a safe pressure in the houses. Both engineer and business man agree that there is something in this, and want to know more, till their questions again become rather hard to answer with any degree of satisfaction. The cost of laying is about the same one way or the other. With the lighter cables and higher voltage, the insulation is more costly, and forms a practical set-off. The leakage, if leakage there is, forms a greater percentage of the whole, and so the amount saved has not that rosy appearance one is accustomed to take for granted when the doctors recommending the system put forth their views. Finally, the weak link in the system is laid bare. One piece of apparatus would put it right. In order to use the greater part of our machinery constantly, power as well as light *must* be distributed. An economical alternate current motor would work a revolution in this system. Then it might be put down without fear and trembling, whereas at present—and *if* such a motor is not forthcoming during the next ten years—the money spent upon alternate current stations is heavily handicapped in dividend earning. Given the motor, all is plain sailing. We had hoped to have heard this phase of the question threshed out at the Civil Engineers, but the discussion took almost entirely a professorial strain concerning details about which the practical man and the business man care very little. These men want to know if there is any prospect of strengthening the weak link. It needs no electrical knowledge to see that the Tesla motor, as exhibited and explained by Prof. Ayrton, is practically valueless, and though rumours exist as to improvements made, and also to the effect that Mr. Ferranti has designed a successful motor, we are fain to doubt the correctness of both rumours. There is no possible doubt but the most important invention required for any purpose whatever in the whole world at the present moment is a good-working, economical alternate current motor. The man who invents such a machine will rank far above Watt, or Gramme, or Edison, and will command a fortune such as no American speculator ever dreamt of—that is, supposing half-a-dozen inventors do not hit upon equally good machines at the same time. Meanwhile, the undue extension of alternate current systems is detrimental to the industry generally, not to lighting specially, inasmuch as the distribution of power, and consequently the manufacture of motors, is a minimum.

THE SERIES ELECTRICAL TRAMWAY AT NORTHFLEET.

For some little time the tramway world generally, and that part of the electrical engineering profession interested in tramway and traction work, have been more or less on the *qui vive* to ascertain the practical outcome of the project undertaken at Northfleet, to open the first electrical tramway in Europe worked upon the "series" underground system.

Profs. Ayrton and Perry in England, in conjunction with the late Prof. Fleeming Jenkin, and working with practical electrical engineers, have developed successfully the series system, with overhead wires for goods transport, under the name of the telpher system; while Prof. Short has carried the principle of series working of tramcar motors into actual operation with considerable success in America. The patents of Ayrton and Perry and Fleeming Jenkin, controlling series working, have been acquired by the Series Electrical Traction Syndicate, Limited, of 11, Queen Victoria-street, E.C. This syndicate, working in conjunction with the enterprising United Electrical Engineering Company (Messrs. Manville and Madgen, managing directors), and the syndicate's consulting engineer, Mr. Joseph Kincaid, M.I.C.E., have developed the scheme into a practical system of tramcar working suitable for English towns, which it was our pleasure to inspect, with other representatives of the technical press, on the opening ceremony on Wednesday.

Advantages of Series Working.

The possible systems for tramway work for towns in this country are limited, practically, to the two systems of (1) accumulator cars carrying their own battery, and (2) lines with underground conductors in conduits. Tram lines with overhead conductors are greatly favoured in the new cities of the United States, and these may be practicable in certain situations in England, as for country tramway work, for electrical subways, and eventually for heavy electric railways proper, as proposed for the Metropolitan; but for towns the two first-mentioned systems are alone allowable. With the underground conduit

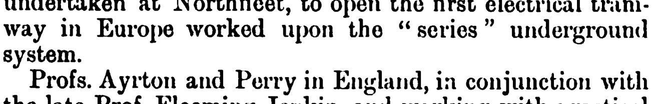

Fig. 1.—Diagram of the Series System.

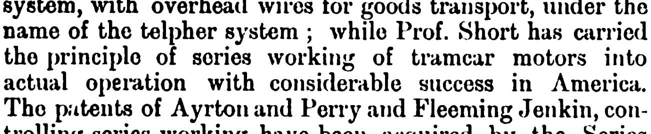

Fig. 2.—Electrical Connections.

Digitized by Google

system there are the two methods of running the electric motors which move the cars: either in parallel from a pair circuits. The great, the enormous advantage of the series system of running is that the copper cable for the tram

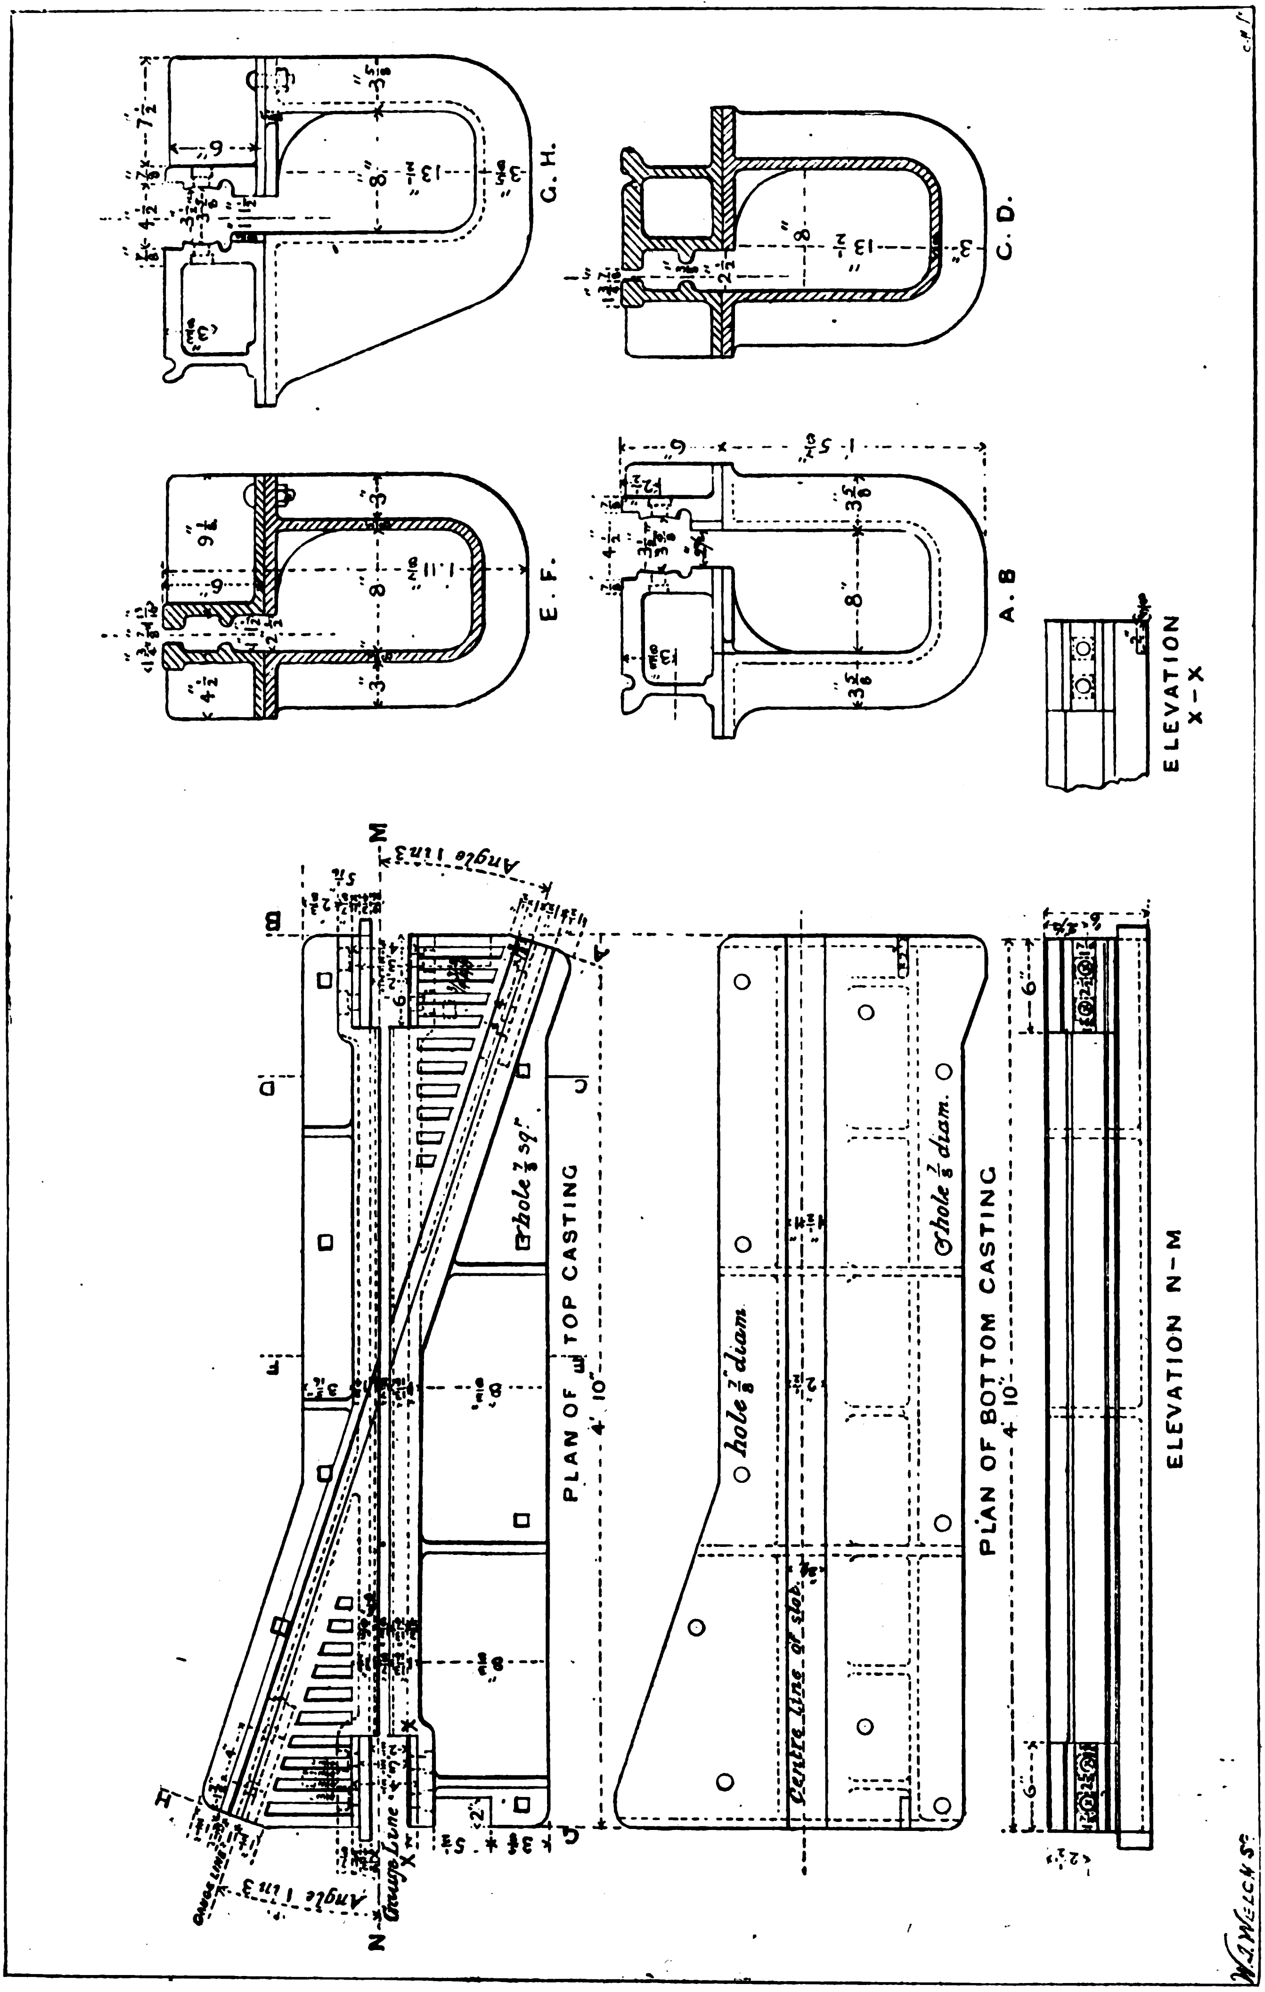

FIG. 3.—The Series Tramway at Northfleet. Details of the Line and Conduits.

of mains, or in series—that is, one after the other upon a single wire (with an unbroken return wire)—as in arc lamp line needs to be only of sufficient diameter to carry the current for a single motor instead of for the whole number,

Digitized by Google

as the same current passes through every motor consecutively, and the saving, both in outlay for copper and in waste of energy in the mains, is vastly in favour of the series method. The objections, on the other hand, are that a very high pressure is needed in the mains to send the current through the whole series, making insulation proportionately difficult, and that if any accident occur to the line that whole series of cars is deprived of motive power. The tramway now opened has been built to show the practicability of running electrical tramcars in series with one another. In the construction of this line it is claimed that the details, both electrical and mechanical, are worked in such a manner as to overcome all the difficulties of insulation and of working, resulting in an underground conduit system, which will be practically applicable to existing or proposed tram lines along the town streets, on a method which ensures by far the most economical employment of electricity.

To make clear the economy of transmission of power by electricity on a line five miles in length by series working as against parallel working for heavy horse-power, such as would be used in railway working, the following instance is given. The electrical pressure now used at the terminals of a motor may be taken at 200 volts. For the transmission of 400 h.p. to the centre of the line of five miles at this pressure, with a conductor of very large area, say, of a resistance of 0·15 ohm per mile—equal to a weight of three tons of copper per mile—the initial power required at the further end would be 2,500 h.p., the difference being lost in resistance of the mains; whereas, with series running with the same pressure of 200 volts at each motor, about 405 h.p. would be required at the engine-house. With a greater pressure—say, 400 volts—the loss, of course, would be much less in the parallel system; but beyond a certain point it will not be safe to raise the pressure at the motors, and the saving in transmitting the power where many cars are running on the same line, will always be greatly in favour of the series method.

CROSS SECTION OF INTERLACING LINE

Fig. 6.

The Principle of Series Traction.

It may be well, before describing the details of the Northfleet tramway, to mention briefly the principle upon which the cars in series are worked according to the patents before mentioned. Granting a line of two or more cars whose motors are in series, we require a dynamo producing an electrical pressure equal to the total pressure required for the whole of the motors added together. We require also a conductor leading the current along the tram line for taking the current to the motors, and a return wire to lead the current back to the machine. We require, besides this, arrangements for interposing in the first-named conductor, contacts to lead the current into the motors at any point all along the route, which must be done without breaking the metallic circuit of the whole line. The principle is illustrated in the accompanying diagram (Fig. 1), where a number of spring contacts normally touching can be parted by the insertion of a moving piece projecting from the car, which enables the current to be led up into the motor and back to the contact without breaking the circuit. The method of joining up the contacts is also shown (Fig. 2), where B, B, are the spring contacts, and the long double line turned over at its end represents diagrammatically, in plan, the moving contact which is fixed to the car, and projects down into the conduit. The lines 1 and 2

represent copper strips, which are, in practice, mounted on a long, thin insulating strip termed the "arrow." The strips turn round the end of the arrow, but do not meet at 3, 3, and the two strips are connected with the motor. The spring contacts—termed "spring jacks"—are connected electrically, as shown by the curved lines. The arrow passing along the conduit opens the spring jacks, and the current from 6 passes in at B, goes through the motor, and out again at B on the other strip. As the car moves along to the right, 6 and 3 will close together, and the current passes along 4, through the motor to 5, and so on. The arrow is constructed somewhat longer than the distance between the spring jacks, hence it never leaves one before it enters the next one, and the metallic contact is therefore always complete. It will be seen that any number of cars can be run on the line without interfering with the electrical continuity, and the cars can follow each other as closely as desired.

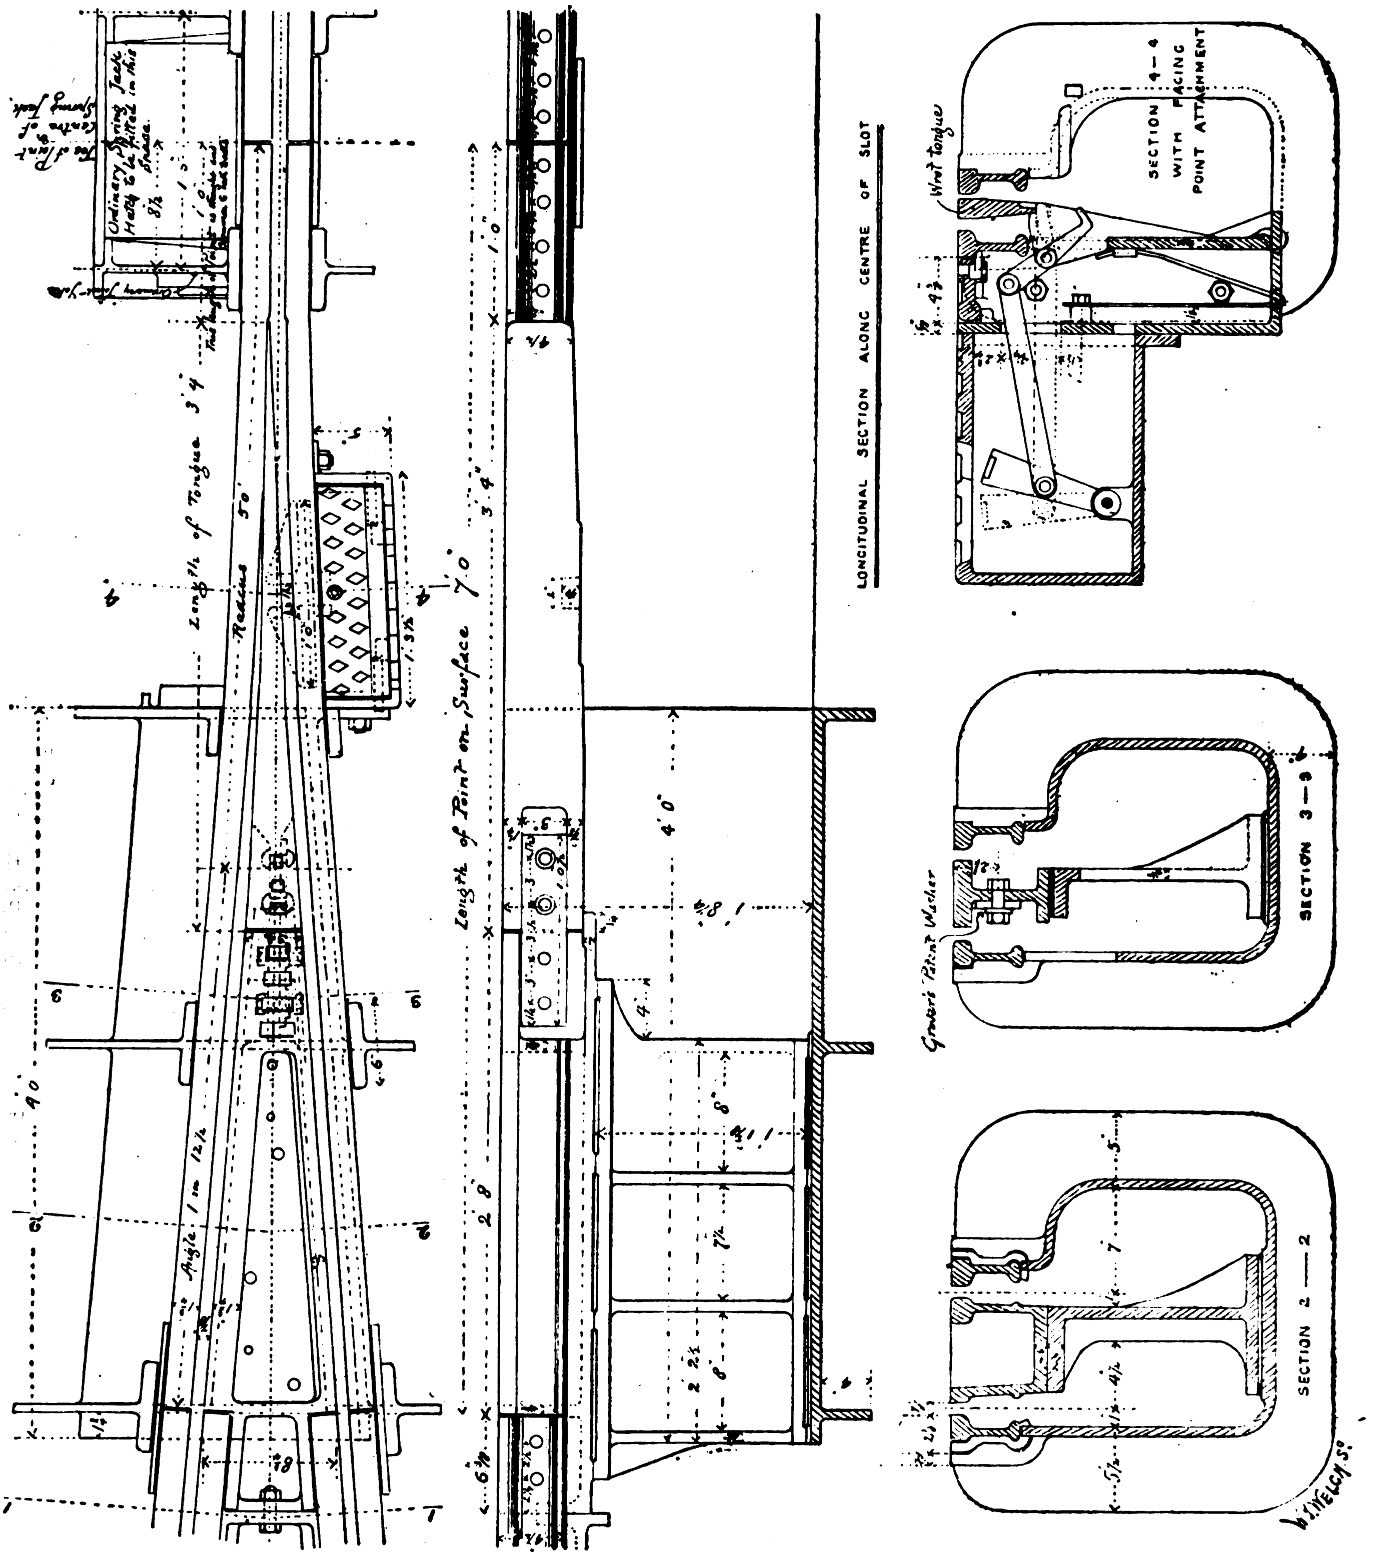

Fig. 7.—Details of the Points.

Mechanical Arrangements.

In appearance, the line has the advantage of not looking much different to an ordinary tram-line, the conduit having been arranged below one of the rails, and not, as is usually the case with cable tramways, centrally with the track. One of the rails is slotted, leaving a space of ⅞ths of an inch; through this slot the holder of the "arrow" projects downwards into the conduit. The spring jack connections are arranged to one side of this slot, so that they cannot be seen from above, and rain or slush falling through the slot cannot touch the connections. In addition, it is impossible for careless or curious persons to obtain a shock from the cable. This construction gives the least possible interference with the roadway, and the conduits are made of sufficient strength to allow for the heavy traffic of a large town, and of the smallest dimensions allowable in order to interfere as little as possible with the water or gas mains beneath the surface of the roads. In all details the

Digitized by Google

construction of the road appears to have been carried out in a mechanical and workmanlike manner, suitable for ordinary business on town streets, and reflects great credit upon the engineers. The construction of the roadwork has been carried out to the designs of the company's engineer, Mr. Kincaid, M.I.C.E., by Messrs. Dick, Kerr, and Co., under the personal supervision of Mr. J. E. Waller, A.M.I.C.E.; the whole of the electrical details being under the direct supervision of Mr. E. Manville.

The Conduit.

The tube, as constructed at Gravesend, is 8in. in width, the bottom being 13in. below the surface of the road. The slot through which contact is made between the underground conductor and the car motor is formed by leaving a space of ⅝in. between two bull-headed rails, somewhat similar to the ordinary Vignole's railway rail, these being 4½in. in depth, with upper flanges 1¾in. wide. The outer of these rails serves as the tread for the tramway wheel, the inner corresponding to the guard-lip of an ordinary tramway rail. These rails are secured through their webs to cast-iron chairs or yokes, at intervals of about 4ft., the yokes being of such section as to leave a clear space below the bottom flange of the rail of 13in. by 8in. The walls of the conduit between the yokes are formed of Portland cement concrete 6in. thick. The rails are laid in lengths of 21ft.; the yokes on either side of the joints being placed 1ft. 5in. apart, centre to centre, and a chamber is formed where these joints occur, covered on the inner side of the rail by a small hatch, 1ft. 4½in. by 8¼in., recessed on the surface, and filled with wood-paving blocks. These chambers serve

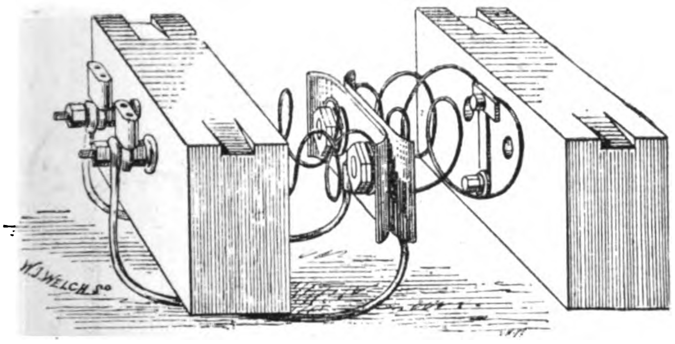

Fig. 8.—The Spring Jack.

for the purpose of access to the spring jacks, or contact points, and also admit of the removal of any dirt which may possibly accumulate in the tube, and, further, gives facility for tightening up the fishplates at the rail joints. The corresponding tramway rail is of the ordinary girder type, the gauge being maintained by means of tiebars attached to the girder rails and the cast-iron yokes, and require no further description.

Fig. 3 shows details of the construction of the line and conduit; Fig. 4 shows a section of the line through the slot; Fig. 5 is a plan showing the box, one of which is placed over each spring jack, to allow of inspection or repair.

The Line.

The line is a portion only of the Gravesend, Rosherville, and Northfleet Tramways, running from Northfleet Station to the company's depôt at Northfleet, a distance of a little over three-quarters of a mile. The line is, therefore, not a long one, and as there are only two cars needed for the working of the line, the system is not seen under its best conditions, which most favourably fit it for a long and crowded line through streets with a heavy traffic and many cars in series. The line was, however, one of the few possessing powers to run by electricity—the main portion of the line is run by horses, and goes to Gravesend, and the portion now under discussion, though short, was considered sufficient for a practical experiment of the system, and has been constructed from the first to be run by electricity. The line comprises some specimens of most of the requirements to be ordinarily dealt with on tramways. There are some pretty stiff gradients of 1 in 30 and 1 in 42; stretches of level working; a turn-out, or change over; a depot, with very sharp curve; double line; single line with crossing places; and the narrowness of one portion of the track has not even allowed of a single line down the middle, and in order to gain space for passing vehicles, a "double-single" track has been laid at this position. In this instance three rails are laid, two of them being conduit rails, and the third an ordinary girder rail, a cross-section of which is shown in Fig. 6. The car, travelling in either direction, uses the centre rail, which in one direction serves as a conduit, but in the other direction takes the place of the ordinary girder rail. At the turn-outs the junction of the conduits underneath the road necessitates the construction of somewhat special points and crossings. The points are provided with movable tongues set so as to automatically direct the traffic to the left-hand side of the road, and in order to avoid risk attendant on having a

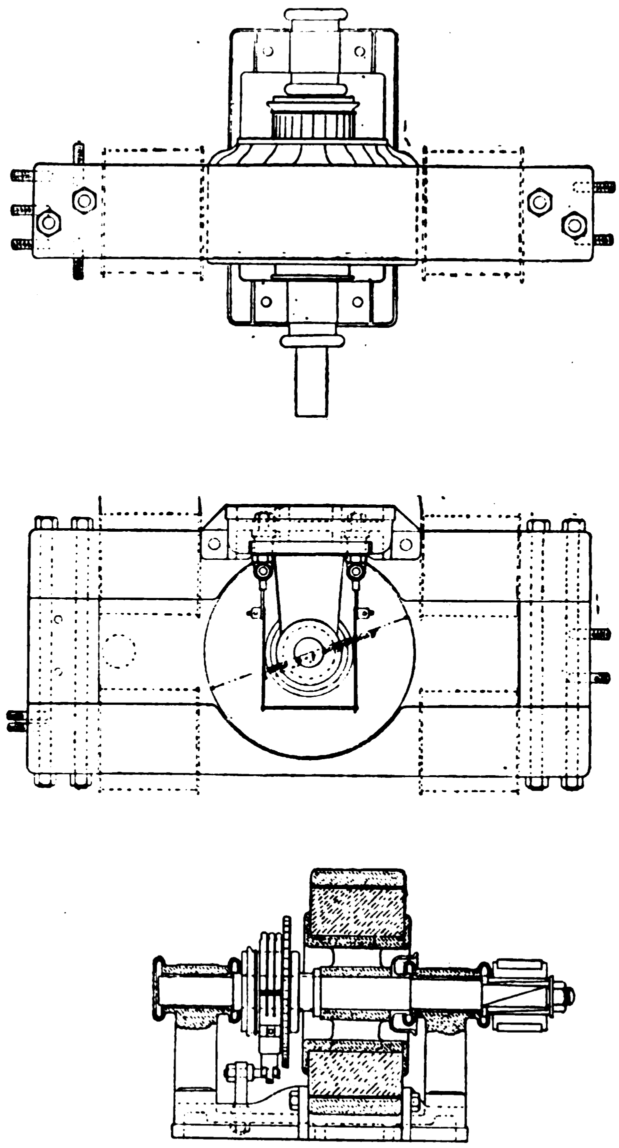

Fig. 10.—Details of the Elwell-Parker Motor used in the Series Cars.

long unsupported tongue forming the roof of the conduits at their junction, a special tumbler has been designed, so formed that it provides a support for the point of the tongue under ordinary conditions, but during the passage of a car it is deflected out of position so as to allow a full clearance for the current collector or "arrow." Where it is necessary, as, for instance, at the terminal fork at the Northfleet Station end of the line, to provide a means by which the cars can be caused to take either track, a claw is pivoted on to the tumbler which can, by means of a lever, be made to engage with the under-surface of the tongue, and thus draw it into the required position. Details of the points are shown in Fig. 7.

Along each side of the track, buried in the concrete, is an earthenware tube 3in. in diameter (*see* Fig. 7, etc.), the ends of which protrude into the cavity formed under the conduit hatches where they are open for access. Into these tubes are drawn lengths of about 21ft. of Henley's

Digitized by Google

highly-insulated ozokerited rubber cable of an insulation resistance of 7,500 megohms per mile. An unbroken return cable is run in a line of similar tubes from the extreme end of the line, it being considered essential in this system that the earth should form no part of the circuit.

These short lengths of highly-insulated cable are the only conductors between the "spring jacks," the conduit between being only for the passage of the arrow, and therefore otherwise empty. In each conduit chamber is placed a "spring jack." These consist of a pair of glazed earthenware blocks, 14in. by 3in. by 4in., supported on brackets cast on to the joint yokes, the blocks facing each other on opposite sides of the tube. To each block is attached, by means of a double spiral spring, a gunmetal casting, curved at the ends, but flat in the centre. The springs are of sufficient strength to press the two castings together with a force of 6lb. The spring jack is shown in Fig. 8. Under the car, and for its full length, is the collector, or "arrow," which consists of two thicknesses of indiarubber belting, each having a broad brass strip riveted to it for nearly its entire length. The nose of the arrow at each end is shod with wrought iron brought to a knife edge, so as to easily force its way in between the two faces of the spring jack. The maximum thickness of the arrow is 1in., which is consequently the extent to which the gunmetal cheeks are separated. The conductor on each side of the arrow is lapped round one end, and an insulated space is left slightly greater than the surface of contact of the spring jack near the extreme ends on opposite side, as already explained in diagram, Fig. 2.

The spring jacks are arranged so that they can be taken out or replaced in the conduit in the course of a few minutes. Short-circuiting pieces are provided to enable the continuity of the circuit to be maintained should a spring jack require to be replaced without interrupting the service during the operation, the car easily running by its own momentum through the distance of 21ft., in which it would receive no current. These spring jacks are very simple pieces of apparatus of small cost, and the contact they make by their surfaces being pressed together is excellent, the resistance of the line being but very little higher than that calculated from the direct resistance of the insulated cables themselves.

The Cars.

The cars used at Northfleet were constructed by the Falcon Engine and Car Works, Loughborough, and are handsome and neat-looking cars of moderate size, without outside seats. Details of the car are shown in Fig. 9, where the gearing of the motor is indicated, and the position of the "arrow," running the length of the car on the conduit beneath the rail, is also shown.

The motors used on these cars, shown in detail in Fig. 9, are of a special type, constructed by Messrs. Elwell- Parker, Limited, Wolverhampton, and were made specially narrow to fit the cars running on a 3ft. 6in. gauge. The connection of the motor to the car is a very satisfactory one, being simple, and allowing of a certain amount of play in running. The front of the motor is supported by two bearings on the driving shaft of the car, the rear being suspended by a strong spiral spring from the car body. The motor shaft is geared directly to a spur wheel on the car wheel shaft, by double helical

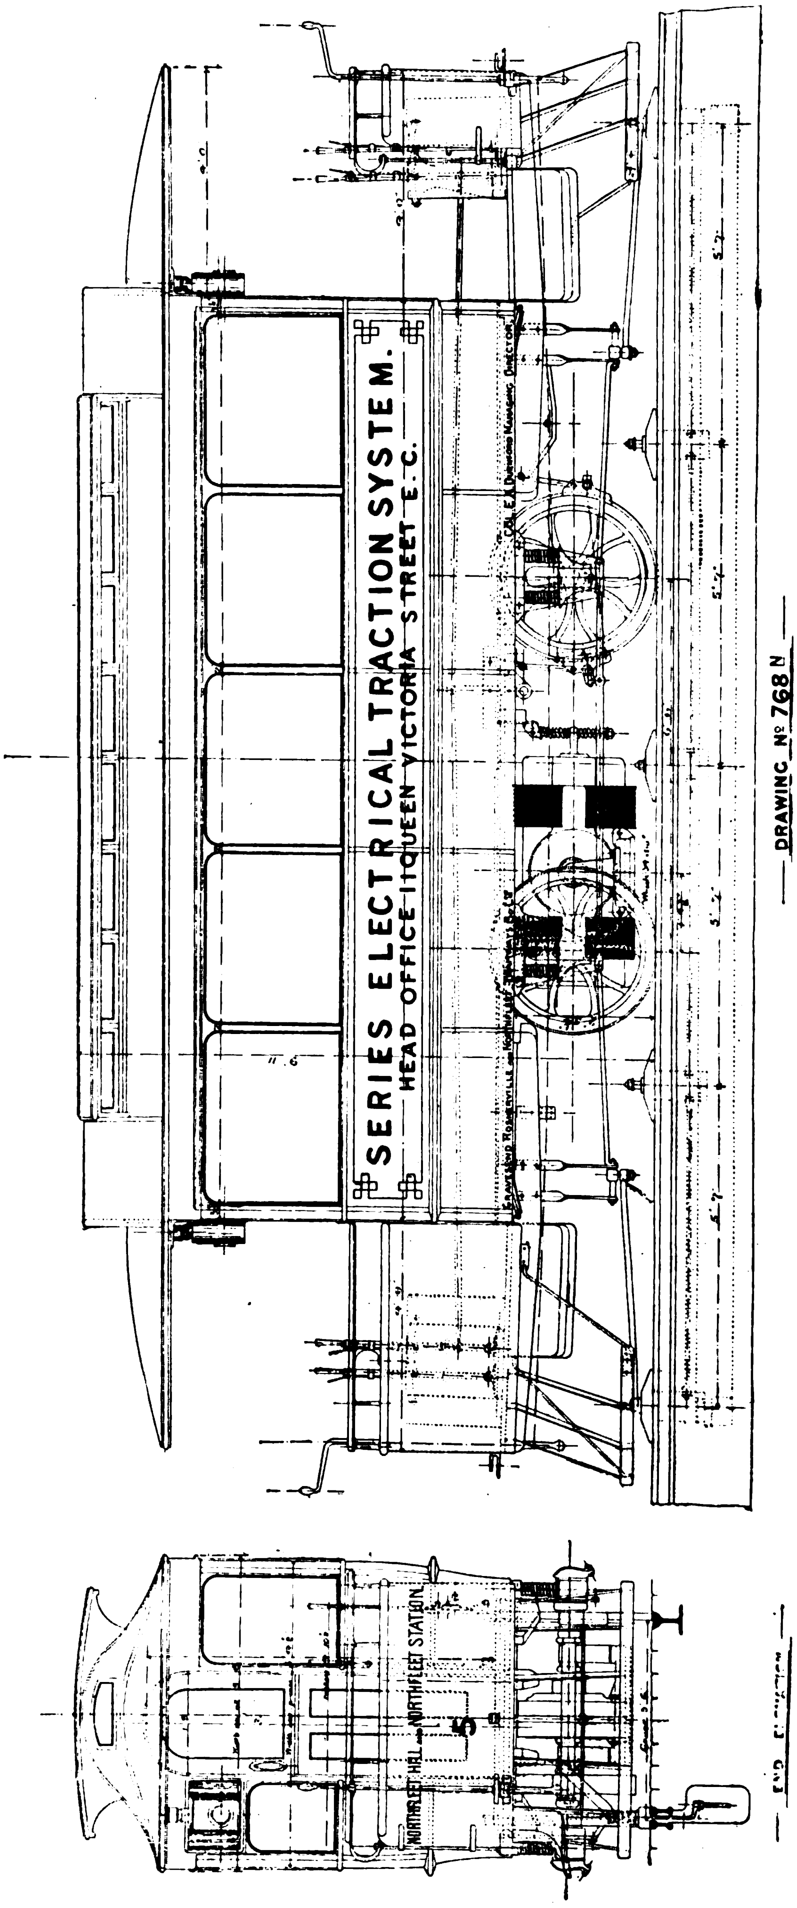

Fig. 9.—Details of the Cars of the Series Tramway.

gearing, the ratio of the wheels being one to four and a half. The motors are run at 400 revolutions per minute, delivering at this speed, when the field-magnets are fully

Digitized by Google

excited, 15 h.p. on the brake. It will be seen that this is a comparatively large motor, running at a slow rate of speed, which, although more costly, the engineers of this line consider more satisfactory than a smaller quick-speed motor for this purpose.

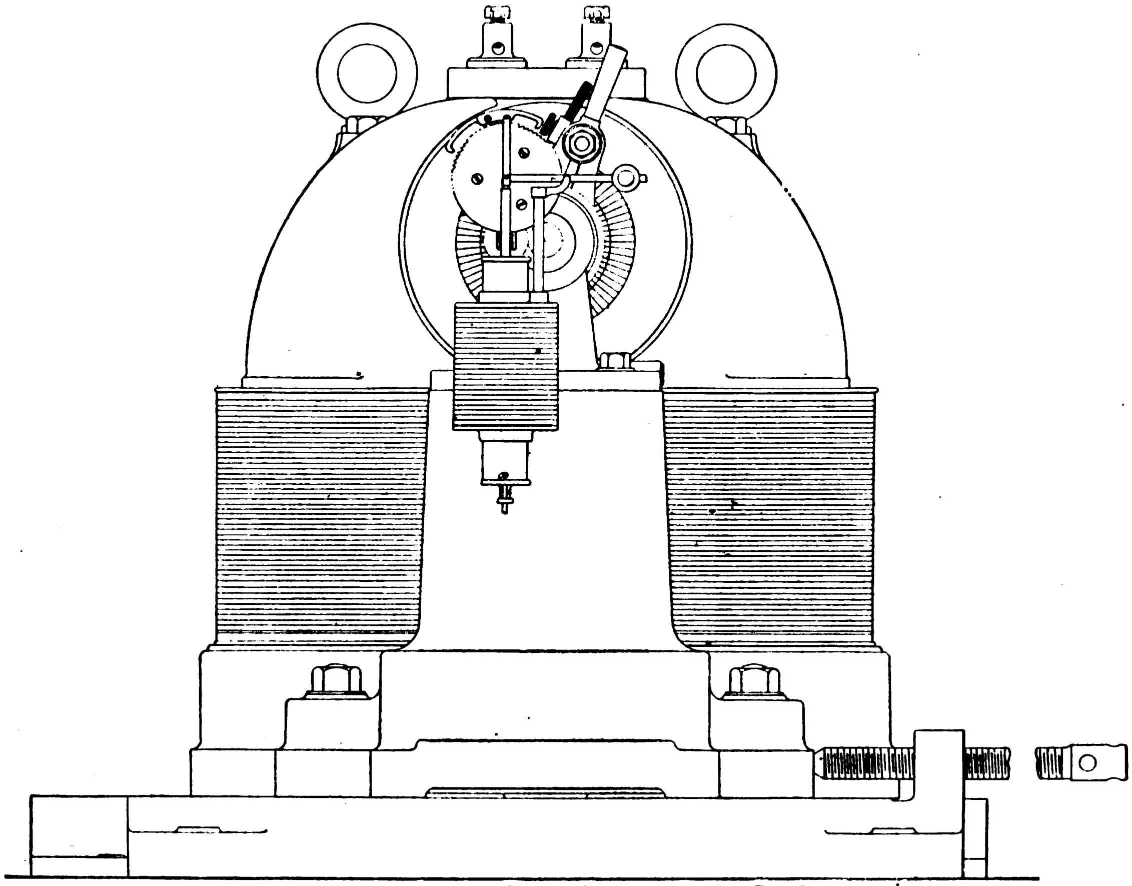

Fig. 11.—The Statter Constant Current Dynamo, showing Regulator.

The "arrow" is shown in Fig. 9 in position under one side of the car. It is supported at distances of 5ft. 7in. on cast-iron bearing blocks, sliding along the surface of the rail. These blocks are connected with iron tiebars, which

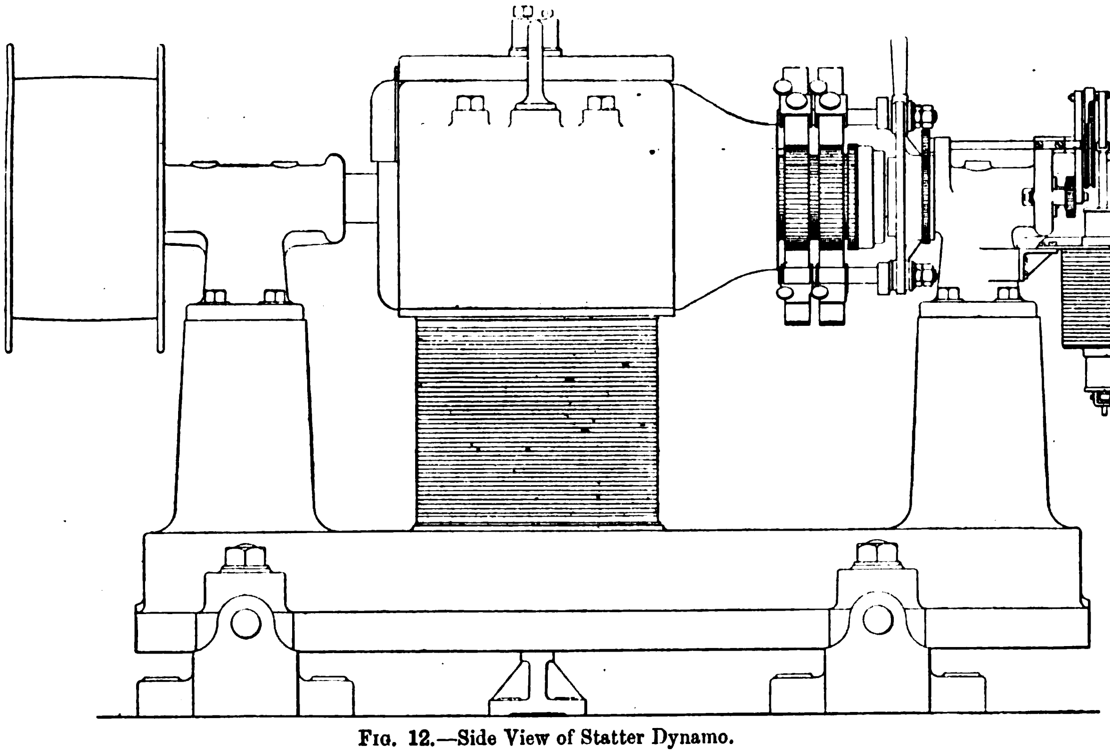

Fig. 12.—Side View of Statter Dynamo.

take all strain off the indiarubbber belt, the whole gear being propelled by the car.

The switches, for regulating the speed of the car, are arranged in strong boxes on the driver's platform, and are similar at each end. They are controlled by substantial handle levers, similar to a railway pointsman's switch, but smaller. One of these introduced a shunt into the fields of the motor of ⅓rd, ⅔rds, or short-circuits them altogether, to vary the speed of the car; the other reverses the position of the brushes, to reverse the direction of the car. The reversing of the motor in this system forms a most efficient break, the car being able to be brought to a standstill in the space of a few feet. An ordinary foot-brake is also attached. Each dynamo is fitted with an ammeter, with the point for 50 amperes—the normal current for the motors—marked in red upon its dial. One of the cars is lighted electrically by the tramway current by means of low resistance Bernstein lamps. Three E.P.S. storage cells are inserted in the circuit, and regulate the pressure to the lamps, which are run five on parallel, with the accumulators at 6·5 volts, taking 10 amperes

Digitized by Google

each. The cells are large enough to run the lamps alone if necessary.

THE ENGINE-HOUSE AND DYNAMO.

The engine-house supplying the power for the line is situated at the depot at the Northfleet end. It consists of a small shed—one of Humphrey's corrugated iron buildings—divided into two portions, one of which is the shelter for the cars, with trench for inspection of the motor and gearing, and the other is the dynamo and engine-house. The engine is a Robey compound underneath type, of 10 h.p. nominal, with locomotive boiler over it.

For series working, it is necessary to maintain a current of constant value in the mains, varying the pressure according to the work being done and the number of cars running. For this purpose the Series Traction Syndicate have selected one of Messrs. Statter and Co.'s constant-current dynamos, a machine which they have found thoroughly satisfactory for this purpose. The Statter dynamo is illustrated in Figs. 10 and 11, the most interesting point being the method of mechanical alteration of the position of the brushes to alter the electrical pressure, and so keep the current constant. This regulation of the brushes is effected by a double ratchet working on a wheel with two sets of teeth on its periphery. The double ratchet is kept in a constant vibratory movement by the rotation of a small pinion on the dynamo shaft itself. This rocks the ratchet by means of an eccentric. The current, passing in series through a solenoid, as shown in Fig. 10, pulls down one side of the ratchet if the current tends to become too great. The toothed wheel is geared to the brushes, and on any variation of pressure in the solenoid the ratchet rapidly shifts the brushes round one way or the other, effecting an instant regulation of the pressure to the required amount, the E.M.F. being continually varied from a few volts to upwards of 400, the current remaining about 50 amperes in the mains, as shown in the ammeters of the cars when in motion. The shape of the pole-pieces of the dynamo is so constructed as to reduce the sparking consequent upon the sudden shifting of the brushes to a minimum, and although the sparking is slightly more than that of a dynamo running under fairly constant load, the sparking, when the brushes are suddenly regulated by the action of the ratchet, is remarkably small, and is, generally, barely perceptible.

The loss in the line seems somewhat heavy in this tramway, where about two miles of $\frac{7}{14}$ cable are used—being given as 140 volts when running open with 50 amperes, practically about a quarter of the whole power. The engineers have used as small a cable as possible to keep the cost of copper down, and, of course, the loss would be no more on this line whether one or 12 cars were running. If preferable, of course, a larger cable with less resistance could be used on other lines.

THE RUNNING.

The trial of the cars on Wednesday was perfectly satisfactory, and several trips were taken with the cars filled to overflowing with numerous representatives of the technical press, together with many electrical and tramway engineers. The cars started off quite easily, ran with very little noise or vibration at a speed varying up to 10 miles an hour, taking the somewhat stiff grades with apparent ease, and being stopped or reversed with admirable facility. The only possible objection that could be raised with the running was the somewhat sudden manner in which the points were taken, giving a jolt to the car. This was due to the length of the wheel base of these cars, which are halfway between the ordinary four-wheel car and the bogie cars, and could be obviated in the usual size of car. The visitors were greatly pleased at the workmanlike appearance of all the details, and the action of running cars in series—the object of this line—must be deemed satisfactorily shown.

The manner in which the details of this, the first Series line in Europe, have been carried has many important advantages.

By the use of highly-insulated cables for the greater portion of the length of the line, and where the spring jacks occur, by having but very small bare surfaces of conductor exposed to the insulating blocks, the possibilities of high insulation are obtained. The divided conductor being in very short lengths, a section of it can be renewed in a very short time without interfering with the traffic of the line. The conduit being perfectly empty, excepting at the "spring jack" chambers, is easily cleaned, and can never require taking up. Another important point is that an incipient fault in the line is easily detected and localised by the car-drivers through the readings of the ammeters on the cars, without the necessity or trouble of elaborate testing.

THE QUESTION OF COST.

It is understood that this line was completely equipped for between £6,000 and £7,000. The ordinary tram-line permanent way may be taken at, say, £7,000 per mile. The additional cost of the series conduit over this price would be about £1,500 in addition. The cost of adaptation to an existent line might be taken as costing from £2,000 to £2,500 per mile for alterations. The cost of equipping the cars with electrical motor and gearing will be a little over £200 per car with the present motors; if with quicker-speed motors they would be somewhat less on first cost. The company when formed, however, will lay themselves out for supplying and constructing series lines, in both conduit and overhead systems, or for altering existing lines at their own expense—and undertaking the running of the cars at so much per car mile, according to circumstances. They will not be absolutely bound by any particular system, but owning the fundamental patents of Fleeming Jenkin, Ayrton and Perry, and having the option of the Short-Nasmyth patents, they will seek to work the series method of traction wherever practicable as the most economical system. The estimated figures show immense saving for suitable lines over all other methods of traction, and it is believed that series tramways can be run for half the present cost of horse traction, which varies from 5d. to 8d. per car mile.

Over steam traction, where the generating motor has to be carried through the streets, the electric system shows great advantage in the saving of the wear and tear of the engines, which are rapidly knocked to pieces on the hard concrete beds necessary for steam tram-lines. Now that the system has been practically demonstrated in England, we may expect a very considerable extension on all hands of electric tramway systems.

COMPANIES' MEETINGS.

ANGLO-AMERICAN BRUSH CORPORATION.

The eighth ordinary meeting of the Anglo-American Brush Electric Light Corporation, Limited, was held on Wednesday at the Cannon-street Hotel, Lord Thurlow (chairman of the Company) presiding.

Mr. E. Garcke (secretary and manager) having read the notice convening the meeting, the minutes of the last meeting were confirmed, and the report and balance-sheet taken as read.

The **Chairman**, after referring to the balance-sheet and to the Electric Lighting Act of last session, went on to speak of the individual business of the Company as follows: We are now building—in fact, very nearly completed—a central lighting station in Chelsea. We have got a large area to supply; we have made most favourable contracts, not only with consumers, but with others manufacturing jointly with ourselves, for the plant that is required. Of course, central lighting installations and central lighting stations are still, to a certain extent, matters of novelty. A certain amount of experience has been gained, but a great deal more undoubtedly remains to be done in the way of ascertaining what is ultimately the best form of building, the best type of machinery, engines, and a thousand other matters. Well, each and all of these matters have received the most careful attention we have been able to give. At Chelsea the lighting system we have adopted is by underground mains and accumulator stations. At Bournemouth it will be by alternating underground and overhead mains, which, of course, in a comparatively rural district like Bournemouth, being more economical has very great advantages in certain cases. The distance is longer, perhaps, and the light not so continuous.

Then, I think, before I turn to the figures—about which, of course, I desire to say something—I should make some allusion, however passing and however unwillingly, to some matters before the law courts. I do not like to discuss them. Still, I think you may fairly expect, and will expect, that I should say something with reference to the pending litigation. Well, of course, the pending litigation is a very important matter. You may be quite sure it has never been absent from our minds during the past 12 months. At the same time, you must not overlook the fact that the exact character of that litigation is not so important to us as to our antagonists. What we have at stake represents one-tenth of our business; but what the Edison and Swan people have at stake represents the whole of their

Digitized by Google

business—at any rate, as a monopoly. Therefore we can, I say, regard this matter with more calmness, perhaps, than our antagonists. It is not a matter of vital importance to us. We can go on without making lamps. We have a very large other business, which is increasing by leaps and bounds, and which, I venture to say, in the course of 18 months or two years, will surprise you all. For that reason I myself, and I think I can speak for everyone of my colleagues, regard this litigation without any anxiety—without reference to any possible result. Well, there is another reason why we can regard that litigation, I think, without overwhelming anxiety, and that is that we are confident in the justice of our cause, and we have very considerable confidence in the final issue. Of course, litigation is an unpleasant thing to be connected with, and I can only say, from my own experience, that it is a thing I am absolutely unacquainted with. I have always made terms, in any matters which have been personal to myself, with any gentlemen who have attempted in any way to get me into litigation, and I shall always pursue the same course in affairs connected with any company in which I happen to have a voice; but the present occasion is an exceptional one. We were met by people who contested the value of patents for which you had paid a very large sum—we could not act according to what might have been our desires and wishes if it had been a private matter. We took the opinion of the first counsel, and that opinion was that we had a good case, and that we ought to fight it to the utmost. We have, therefore, fought it as far as it has gone, and the result has been one thing in one Court and the other thing in the next Court, and it has been a perfect see-saw. The uncertainty of the law is proverbial, and has been certainly well exemplified in this case. You know the judgment of Justice Kay was considered at the time a very powerful decision. That went to appeal and was reversed. We have now notified our intention of taking it to the House of Lords, which is the highest court of appeal in the country. I do not know that even when we have got the decision of the House of Lords it need be absolutely final in this case, for reasons which I need not enter into; but, at any rate, we felt we had no alternative on the present occasion but to stick to our guns and take it to the House of Lords, and have accordingly intimated our intention of so doing. At the same time, as I mentioned just now, my own personal feelings are always in favour of making terms with your enemies while you are in the way—meeting them; and I think this Board has never neglected an opportunity of approaching the opposite side in the most conciliatory spirit, and with every desire to meet them half way, or as fully as I am sure any gentleman in this room would desire. I am bound to say that our antagonists have not shown the same desire, or, at any rate, the same conciliatory feeling; on the contrary, they have manifested a desire to continue this suit, and to really put us, if I may use the expression, to every inconvenience in their power. That may be all right and justifiable in a thing of this sort; and, as I said before, their position being different from ours, the lawsuit being a vital one to them, it is hardly possible for them to approach it with the same calmness and independence as we can ourselves. However, I can assure you that while we have deemed it our duty to take this matter to the House of Lords, still we are open to be approached by the Edison and Swan people at any moment. We are willing to make terms with them, so as to save your interests and to save your honour, in any reasonable way that can be suggested, and I am not without hopes that during the interval that must elapse before this case can be heard in the House of Lords, something may be done in the way of arriving at a conclusion satisfactory to both parties. Beyond that I think I need say very little on that point.

We have one other case pending at present. It is a case against King, Brown, and Co., an Edinburgh company, in reference to compound winding. You know we claim to have the control of the patents for compound winding and dynamos. That has been admitted by all English manufacturers, and they are paying us a royalty, which amounts to a very nice little income to us during a portion of these years. The only firm which has contested our rights is King, Brown, and Co., of Edinburgh. We have pursued them in the courts, and the case is still pending. Under these circumstances, I will not depart from the very proper rule, that any expression of opinion on the merits of that case is unadvisable. And now I think you will permit me to turn to the accounts, which are as satisfactory as the report; indeed, one cannot be satisfactory without the other. You will have noticed that these accounts and this report have been accompanied, in transmission to the shareholders, with a diagram, which is, perhaps, somewhat unusual; but we considered it was, perhaps, the readiest way of bringing the facts to the comprehension of the shareholders, to show to what extent the volume of business has increased, to what extent the gross profits have increased, and to what extent the general charges have, I am glad to say, decreased, or remain stationary. I think that diagram is a very remarkable paper. You see that in the five years from 1883 to 1888 the volume of business has increased from 100, which we put at par, to 307—over 200 per cent. in five years. You see that during the same period of time the gross profits have increased 254 per cent. That, I think, is very remarkable, and I think I can fairly challenge any other electric light company in the world to show similar results. And we have still one strong feature to dwell upon, and that is that the general charges have not increased—hardly at all—not only not increased in the same ratio, but, if anything, have shown a tendency to decrease. That can only be due to one thing—good management and economy, as introduced by our general manager, Mr. Garcke, in every branch of the administration. Our general charges have fallen from 100 per cent. to 65 per cent., and I challenge any other electric lighting company in the world to produce a similar and equally satisfactory diagram of their last five years' work.

Well, then, to turn to the profit and loss account for this year, you will see the gross profit of this year's transactions and trading reach the very respectable figure of £28,049. I think that is very satisfactory; and to this we have to add a balance, carried forward from last year, of £2,500, making an available balance of £30,612 to carry to general account. You will see on the other side the standing charges. I have referred to them already, generally; but I think I ought to point out that the standing charges show only an increase of 7 per cent. in themselves. The business itself has increased 50 per cent. during the last 12 months, and the standing charges have only increased by 7 per cent. Those are figures I should like you to bear in your minds. Turning to the balance-sheet, you see that the share capital has been increased by the issue of 1,160 new shares. Those shares are issued for the purpose of increasing our working capital, which, as I think you may well imagine, we had every desire to do by every legitimate means, to enable us to undertake the large contracts which are daily being placed before us, and which we are naturally loth to send away to swell the volume of business of our competitors in the trade. When I speak of our competitors in the trade I think it may be interesting to you to know that we have not had it all to ourselves, this prosperity, and this increasing prosperity, in electrical business. The Chairman stated that the number of electrical engineers in England had increased from 57 in 1883 to 260 in 1888, and said, when it was considered what the Company had done in face of this increase during the past twelve months, shareholders need not despair of the Company holding its own in the future. He then described the amounts in detail, and said: I consider that the result that has been achieved has been achieved by the continuous and united efforts—all in the same direction, enhanced efficiency combined with economy—not only of the Board here present before you, some of whom take the greatest interest and have the greatest technical knowledge of all your affairs and of everything that transpires in these manufactures, but also of your general manager (Mr. Garcke), your superintendent engineer (Mr. Raworth), your electrician (Mr. Sellon), your other electrician (Mr. Mordey), and your factory manager (Mr. Sillar). To every one of these gentlemen, in their respective offices, your thanks are due for the result which has been achieved. You stand to-day with a realised profit, available to pay, if you choose to take it, a 5 per cent. dividend on the whole of the share capital of this Company. It remains for you to decide this morning what you will do with that balance—whether you will put it in your pockets as a 5 per cent. dividend for the 12 months, or whether you will take the more prudent course, which we undoubtedly recommend, of leaving that in abeyance until litigation is over. I have no doubt in my own mind that that is the wiser course to pursue. It is the course that has been pursued by our opponents, the Edison and Swan. They had a large balance of profit on their last year's working, but did not distribute it among their members. They have held it in abeyance to meet eventualities. I think it would be unwise for us not to take the same prudent course; but if you should differ from the feeling of the Board on this point, it is undoubtedly within your competence at the present moment to elect to take that as dividend, and to divide the profit of £12,885 which stands to your credit on this year's balance-sheet.

Then I have only one thing more to say, and that is that this business is increasing, and increasing very rapidly. I consider we have overcome our difficulties of manufacture. We have undoubtedly further improvements and economies to effect. It is impossible to go on manufacturing from day to day without perceiving opportunities of manufacturing under more economical circumstances. We might follow the example of some of our friends, and take our works into the country, where labour and coal and other matters are undoubtedly considerably cheaper. Then there would be expense of moving, and other things. We may pursue that course a little later; for the present we are satisfied to remain where we are, because, while there are some of those drawbacks to which I have alluded to carrying on a manufacturing business in London, there are incidental advantages. When strangers, especially from foreign countries and the colonies—with which we do a very large business—come to London, it is a satisfaction to them to be able to see our works, to see the class of plant and machinery we have, and in some cases we supply plant and machinery to some of our colonial customers, and it is much more convenient—and I believe in many cases much more remunerative—to be able to show it to them on the ground than to take them into the provinces to see it. I feel sure that by having our works in London we get orders—and very many of them large orders—which we would not obtain if they were situated a hundred or a couple of hundred miles from London. For these reasons a move into the Midlands or elsewhere is not to be too lightly undertaken; but it is a matter we have been carefully considering, and will continue to consider, and there is no doubt that if it were done large economies would ultimately ensue. Well, what I was going to say was this—our business is increasing; it is quite necessary that our capital should increase in a corresponding manner. We have got every shilling in the business now that we are able to put into it; we have got a provision amount in it of £17,816; we have got a certain amount of that £12,885 in it, although we have nearly £10,000, as you see, at the banker's on that date (December 31). Of course, you may say we owe our creditors £22,000. It might be possible, of course, to increase that, and carry on a large business with still greater liabilities; but you know what that means—you do not get your discount on cash payments. It is necessary to avail ourselves of all these kinds of advantages. Therefore, I say that to carry on this business remuneratively in the future, and to be able to watch its growth with equanimity, and derive the greatest possible advantages from it, it will be necessary for us and for you, sooner or later, to largely increase our capital.

There is another reason why that is necessary. Look at these other companies that are doing business in the same way! Look at two or three of these lighting companies that have been recently formed in London, with their millions of capital—the London Electricity Supply Company, and one or two others that I need not mention. You know the amount of money they go to work with—a million or two millions of capital—and they have the means

Digitized by Google

of raising that capital. Undoubtedly, if we are to compete on fair and equal terms with these other gentlemen, in course of time we must have our millions too. We have not seen this thing grow without seeing the interest that would naturally come to us if it is proved that the business is a profitable one. We have now proved the business is a profitable one—we have proved that to a greater extent than any of our competitors, and I feel confident that when the time comes, as I believe it will before very long, that we go to the public for a large increase of capital, that attempt on our part will be met by a most willing response from London and the provinces, by gentlemen who have money to invest, and take an interest in this new and increasing industry.

Gentlemen, I have nothing to add to what I have said, but I have to thank you before I sit down for the continued confidence in myself and the Board with which I have the honour to be associated. I can only say that we will continue, to the best of our abilities, to work for you, and we hope to justify the continuance of the confidence which has hitherto been extended to us, and without which I feel, for one, it would have been impossible for us to have brought this business to the satisfactory position that it now occupies. I therefore, gentlemen, beg to move: "That the report of the Directors and the statement of accounts up to December 31, 1888, now presented to the shareholders, be received, and the same be hereby adopted."

Mr. J. S. Sellon seconded the motion.

The **Chairman** answered some questions addressed to him, mentioning that the Company had successfully lighted nearly all the great exhibitions of late years, and had practically got a contract for a considerable slice of work at the Paris Exhibition.

The motion was carried unanimously.

On the motion of **Mr. Sellon**, seconded by **Mr. Copland**, Lord Thurlow and Colonel Frederick G. Steuart were re-elected directors, and Messrs. Cooper Bros. and Co. were reappointed auditors on the proposition of **Mr. Copland**, seconded by **Mr. Blessley.**

Mr. Weir moved a vote of thanks to the Chairman and other Directors for their successful pioneering of electric lighting, and also thanked the officials for their exertions.

This was seconded by **Mr. Hart** and carried, and the Chairman's acknowledgments concluded the meeting.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The Directors of this Company have declared an interim dividend of 3s. per share, or at a rate of 6 per cent. per annum, tax free, for the quarter ended December 31, payable on the 25th inst. The receipts for the week ended March 8 amounted to £5,575.

Oriental Telephone Company.—The Directors of this Company have resolved, subject to final audit of the accounts, to recommend to the shareholders a dividend of 3 per cent., free of income tax, on the paid-up capital of the Company (other than the vendors' shares) for the year ending December 31 last, placing £2,500 to reserve, and writing off the whole of the balance of the preliminary expenses—amounting to £3,000, leaving an amount of some £500 to be carried forward.

Western and Brazilian Telegraph Company, Limited.—The Directors of this Company have called a special meeting of the shareholders for the 19th inst., for the purpose of ratifying an agreement made between the Company and the Brazilian Submarine Telegraph Company, Limited, in respect of the working of the lines of the two companies and the division of the traffic receipts thereof. The traffic receipts of the Western and Brazilian Telegraph Company for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Telegraph Company, were £4,401.

Direct Spanish Telegraph Company, Limited.—This Company in their report for the half-year ended December 31st state that the accounts show a profit balance of £5,720, and that, after putting £2,500 to the reserve fund, which amounts to £13,660, there is an available balance of £3,220, out of which they recommend a dividend at the rate of 10 per cent. per annum on the preference, and one at the rate of 4 per cent. per annum, tax free, on the ordinary shares, making with the previous distribution 4½ per cent. for 1888, against 4 per cent. for 1887, £723 being brought forward towards the payment of the portion of the cost of the repairs of the Bilbao cable charged to revenue.

PROVISIONAL PATENTS, 1889.

MARCH 5.

3808. **Improvements in electric signals for engine shafts.** James Clark Ricketson, 52, Chancery-lane, London. (Complete specification.)

3813. **Improvements in telephonic switching apparatus.** Alfred Rosling Bennett, 62, St. Vincent-street, Glasgow. (Complete specification.)

3835. **A new or improved incandescent electric lamp.** Ernst Böhm, 66, Stowe-road, Shepherd's Bush.

3836. **Improvements in electric arc lamps.** Luther Hanson, Commercial-street, Halifax.

3844. **Improvements in or relating to regulators for systems of electrical distribution.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Westinghouse Electric Company, United States.)

3870. **Improvements in electric motors and dynamo-electric machines.** Henry Harris Lake, 45, Southampton-buildings, London. (Orazio Lugo, United States.) (Complete specification.)

3881. **Improvements in the method of and apparatus for regulating electric currents.** Joseph Wilhelmus Balet, 53, Chancery-lane, London. (Complete specification.)

MARCH 6.

3907. **Improvements in electrical switches.** Thomas Parker and Edmund Scott Gustave Rees, 70, Market-street, Manchester.

3922. **Improvements in the methods of suspending electric or other lights, applicable to other purposes.** Harry Christie Harold, Robert Jenkins, and Samuel Johnson, 30 and 31, St. Swithin's-lane, London.

3954. **Improvements in electric signalling systems and apparatus for railways.** Philip Middleton Justice, 55 and 56, Chancery-lane, Middlesex. (Thomas Parramore Worrall, United States.) (Complete specification.)

3967. **Improvements in arc electric lamps.** Thomas Robinson, 47, Lincoln's-inn-fields, London.

3971. **Improved compound or admixture of ingredients suitable for producing electric energy.** John James Rathbone, 166, Fleet-street, London.

MARCH 7.

3990. **Improvements in dynamo-electric machines, whether generators or motors.** William Phillips Thompson, 6, Lord-street, Liverpool. (La Compagnie Continentale Edison, France.)

4004. **Improvements in electric apparatus which may be combined with mechanical apparatus for the transmission of sound, the combined apparatus may also be applied to other useful purposes.** Robert Henelade Courtenay, 6, Anerley-street, Battersea Park-road, Surrey.

4029. **Improvements in the distribution of electric energy.** George Wilkinson, 17, Coleman-street.

MARCH 8.

4049. **Improvements relating to electric lamps.** William Frederick Smith and James Sinclair, 45, Southampton-buildings, London.

4125. **Improvements in holders for incandescence electric lamps.** Walter Osmond Rooper, 115, Cannon-street, London.

MARCH 9.

4171. **Improvements in accumulators or secondary batteries.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (F. C. Glaser, Germany.)

4192. **A new or improved regulator for transformed electric currents.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery-lane, London. (Alfred Mills Taylor, India.)

NOTES.

Philippine Islands.—A cable is about to be established between the islands of Luzon and Visayas in the Philippine Islands.

Mexico.—Notices from Mexico state that the "Faraday" has just laid a cable between Coatzacoalcos in Mexico and Galveston in Texas.

Madrid.—At a ball recently given by the Commercial Union of Madrid, the rooms were splendidly lighted by 337 incandescent lamps.

Chelsea.—The Chelsea Vestry have assented to the proposed extension of the area of supply by the Chelsea Electric Supply Company, Limited.

Reduction of Tariff.—The Brazilian Submarine Telegraph Company notify a reduction of their tariff to Madeira, Cape Verde Islands, and South America.

Extension of Works.—Owing to increase of business Messrs. F. Wiggins and Sons have taken additional premises at 102, Minories, which is in telephonic communication with their works at 10, Tower-hill.

Underground Men.—If enterprising young electrical engineers want appointments, it would be well for some of them to specially study underground electric light cables, and how to design and superintend the laying of them. There will be plenty of demand for such men soon.

Telegraph Rates to Germany.—The *Reichsanzeiger* publishes the announcement of a reduction in the telegraphic rate between Germany and Great Britain and Ireland. In future the tariff will be 15pf. instead of as hitherto 20pf. per word. The new tariff will take effect on April 1st.

Monte Carlo.—The installation of the electric light at Monte Carlo carried out by the firm of Lombard Gerin, of Lyons, is now completed. The lighting, which comprises some 1,500 lamps, is a complete success, and considerably adds to the magnificence and physical comfort of this pleasure resort.

Registering Voltmeters.—An instrument giving a curve like a barometer register is the kind of voltmeter that should be used in electric light stations. MM. Richard Frères have introduced such a registering voltmeter in France, and the instrument is in use with great success at the central station at Pau.

Electric Lift in Paris.—The immense building at the Paris Exhibition, the Palais du Machines, for the reception of machinery in motion is to have an electric lift in one corner which will ascend to the height of about 130ft. The Compagnie Electrique, of Paris, are supplying the necessary apparatus for working this lift by an electric motor.

Spain.—An installation of electric light has been erected at Catalayud by Don José Alonso, an engineer of Sarragossa. The installation obtains its power from a waterfall by means of a turbine of 30 h.p., and comprises two Gramme dynamos, one of which is for reserve, running at 800 revolutions and 110 volts, constructed by Aboilard, of Paris.

Underground Wires.—The burying of electric wires is to be hastened in Pennsylvania by a Bill now before the Senate of that State prohibiting all suspended electric wires in cities of more than 30,000 inhabitants. The bill is intended to go into effect after August 1, 1889, and a penalty of £100 per day is prescribed for all violations of the provisions of the Bill.

Railway Rates.—The London Chamber of Commerce are agitating for alteration of the railway rates. Persons having objections to the present rates must lodge them with the Board of Trade and the railway companies not later than April 9. Members wishing to pass their objections through the Chamber of Commerce should send copies in triplicate, on forms supplied, by the 1st April at latest.

Board of Trade Enquiry.—We learn that the Board of Trade have appointed Major Marindin, C.M.G., R.E., to hold an enquiry with reference to the various applications for provisional orders and licenses under the Electric Lighting Acts which they have received in respect of the metropolis. The enquiry will be held at 8, Richmond-terrace, Whitehall, and will commence at 10.30 on Wednesday, April 3.

S.S. Oruba.—The Naval Construction and Armaments Company have this week launched from their yard at Barrow the first of two large vessels they are building for the Pacific Steam Navigation Company for the trade between Liverpool and Valparaiso. This vessel is 450ft. long, with a gross tonnage of 6,000 tons. There is accommodation for 990 passengers, and the vessel has a complete installation of electric light in every part, no less than 500 incandescent lamps having been fitted.

Electric Traction in France.—The local railway which is being constructed between Clermont-Ferrand and Royat will be run by electricity. The motive power will be produced by a 150 h.p. engine near Montferrand. The current, at a pressure of 500 volts, will be taken to the carriages by an overhead; the rails of the line will serve as the return conductor. The trains will be formed of one or two carriages, each to contain 50 persons; these carriages are being made at the works of La Buire, at Lyons.

Electric Heaters for Railways.—The Grand Trunk Railway of America is preparing to make experiments with an electric car-heating apparatus invented by Mr. Roe Fuller, an employé in the Grand Trunk shops at Portland, Me. It consists of a dynamo placed in the baggage car, power being taken from the moving axles. A metal bar is placed in a tank of water in each car. Pipes from the tanks extend all round the car. The metal bar is to be heated by an electric current, thus heating the water in the tank and pipes.

Accident Insurance.—Mr. Maynard, of the L. C. and D. Railway, Bromley, Kent, who, as agent, took so great an interest in obtaining the concession relative to accident insurance, writes to say that he will be glad to receive the names of those desirous of insuring, and to act as agent in obtaining their acceptances. If any reader experiences any difficulties in getting his proposal accepted, we are quite sure he cannot do better than correspond with Mr. Maynard, and it would not be amiss if those now insured at the higher rate were to do so likewise.

Newcastle.—Two central station schemes are on foot at Newcastle-on-Tyne. One of these, it is understood, will be run with the Parson's high-speed steam turbo-generators and dynamos. We shall be interested in seeing the application of these machines to the work of central station lighting. Some interesting details should be forthcoming before the Institution of Electrical Engineers if the Parson's generators and dynamos are set to work practically on a large scale—high speed in this case being, as is well known,

Digitized by Google

no misnomer, a speed of from 10,000 to 18,000 revolutions per minute being obtained.

Cheap Electric Light.—We hear, on what we believe to be good authority, that a certain town council has had the offer made to it by a contractor to supply and maintain any number of arc lamps over a minimum of six for the price of £12 per arc lamp per annum. Water-power was available, and the offer was extraordinarily cheap, presumably on the chance of afterwards introducing the benefit (with profit) of house lighting to private individuals. But no—the offer was not accepted. Fourteen candle-power gas was even a little cheaper than 2,000-c.p arcs at this price, and gas it remains.

Tenders for Galway.—For lighting the harbour of Galway, Ireland, for the Galway Harbour Commissioners, the following tenders have been received:—The Galway Electric Company, 16 c.p. incandescent, £1. 19s. 6d. per annum; 25 c.p., £2. 8s.; 32 c.p., £2. 15s.; 50 c.p., £3. 10s.; 100 c.p., £5. 10s. Arc lamps, 500 c.p., £12; 1,000 do., £20 (accepted). Galway Gas Light Company, 16 candles, £2; 100 do., £7. 10s. Galway is peculiarly well supplied with water power, some 50,000 h.p. now running to waste; and it is proposed to utilise some of this power for lighting the town and harbour.

Laing, Wharton, and Down.—It has been understood for some little time past that steps were being taken to form the business of Messrs. Laing, Wharton, and Down into a limited company. We are now notified that that portion of the business relating to the Thomson-Houston system of electric lighting has been formed into a limited company, under the title of the "Laing, Wharton, and Down Construction Syndicate, Limited," with a capital of £40,000. None of the shares will, however, be offered to the public, as the whole of the issue, £30,000, has been privately subscribed.

Inserting Batteries in Cars.—To obviate the difficulties in manipulating storage batteries used in accumulator cars, Mr. John A. Brill, carbuilder, of Philadelphia, uses a method by which the batteries are easily inserted and removed from the ends of the cars. A door is made in the ends of the cars, and also a flap in the dashboard. Rollers, or wheels, are provided in the car floor below the seats, upon which are run the battery sections, properly connected, so that the whole can be run in at once and automatically connect themselves. The batteries are brought to the cars on trucks running on narrow-gauge rails, which branch off from the main track.

Removal.—The General Electric Company have removed their offices, warehouse, and showrooms from Great St. Thomas Apostle, E.C., to 71, Queen Victoria-street, E.C., a large building four houses west of the Mansion House Station. This step has been necessitated in consequence of the increase in the demand for electrical goods, due mainly to the extension made at their works in Manchester, which has resulted in the receipt of large orders for electrical fittings for the foreign as well as the home trade. This extension of business in electrical fittings and general apparatus is another sign of the rapid progress which the electrical industry has made during the last few years.

Faraday and Son's Fittings.—The great increase in the electric lighting industry of the past few months has had its influence upon the makers of artistic fittings. Messrs. Faraday and Sons have found it necessary to extend their works, and at the beginning of the new year took the lease of some adjoining premises in Berners-street, W. These are now opened in extension of their manufactory, and form an important addition to their facilities for turning out electric light fitttngs. We presume all our readers who buy fittings have possessed themselves of one of Messrs. Faraday's catalogues, which contain a large selection of very pretty and artistic pendants, brackets, and other fittings.

Electrical Engineering at Silvertown.—The extended demand for electric lighting machinery has enabled the India Rubber Company, of Silvertown, to construct a large new building for the manufacture of their Silvertown dynamos. The company have just arranged for a small private central station for 1,500 lights in the City, and it is also not unlikely that considerable work in the coming business—electric traction—will be shortly undertaken. The company are also exceedingly busy in bringing out the Weymersch battery, of which such a favourable report was issued some months ago. The battery has the very useful peculiarity, among other good qualities, of rising slightly in E.M.F. as more current is taken. Electric light cable work generally is also very brisk.

Electric Drawbridge.—An electric motor for working a drawbridge is in successful operation at Bridgeport, Connecticut, U.S. The draw weighs some 300 tons, and is attached to the bridge over the Pequonnock. It is believed that this is the first instance of this kind worked by motor. As the draw must be opened an average of twenty times daily throughout the year, the labour is great as well as expensive. The city authorities, with a view to lessen both, have introduced an electric motor of 7½ h.p., the force being transmitted from the Bridgeport electric light plant, half a mile away. This motor makes 1,600 revolutions each minute, and by the use of gearing the motion is reduced to nine revolutions, producing a power both steady and sure. The motor may be reversed, so as to turn the draw either way.

Change of Office.—The engineer's office of the Metropolitan Electric Supply Company has been removed this week from 5, Whitehall-yard to 4, Waterloo-place, S.W. The change is due to the greatly extended amount of work undertaken, and the offices are admirably suited to the purposes required. The whole house has been taken, and is handsomely and comfortably fitted. Mr. J. E. H. Gordon has a handsome private office on the second floor, with the drawing office in the room adjoining, and Mr. F. Bailey has also his office on the same floor; while Mr. Claremont, general manager, has his offices on the first floor, but the secretary's office remains at Winchester-house, Broad-street. The large advertisement of the name of the company was put up in one night to avoid damage and annoyance to the neighbours, and is now to be seen of all men passing westwards, in one of the finest situations in London.

Original Investigation by Students.—Mr. G. H. Shepardson, writing from Cornell University to the *Electrical World*, says: "Mr. J. W. Granger, instructor in the Sibley College blacksmith shop, has succeeded in *welding copper at the forge*, and has made a copper chain of $\frac{3}{16}$in. copper wire. This feat, I believe, has never been accomplished before. Several original investigations are being carried on in the laboratories. By making small changes in a Ball unipolar series dynamo, I have succeeded in getting a well-regulated *constant potential* from it. Investigations by Messrs. Nakano and Merritt have shown that of the total energy radiated by an incandescent lamp at normal

Digitized by Google

candle power about 6 per cent. is light, while with an arc lamp only 3 to 4 per cent. is light; proving that for a given actual amount of light radiated the *incandescent lamp is more efficient than the arc.* This is contrary to common belief."

Pumpelly Storage Battery.—Mr. Pumpelly, of Chicago, has introduced a form of storage battery with horizontal plates, to obviate the difficulties due to detachment of active material and buckling. The horizontal plates—6½in. square in the standard cell—are in the form of a gridiron, and perforated to hold the largest amount of minium in a secure manner, and between each pair of plates is placed a sheet of asbestos cloth, so that if by any chance or accident any peroxide falls it is caught by the cloth, and cannot cause a short circuit. The plates have taper hubs on the ends, covered with rubber, into which the next plate fits securely, and through these is threaded a copper connecting rod, which is coated with lead to protect it from the acid. The standard cell weighs 32lb., and has a capacity of 240 ampere-hours, with an economic discharge of 25 amperes. The internal resistance in discharge is ·003 ohm.

Electric Tramway Materials.—Now that electric tramways bid fair to be the order of the day, it may be interesting to mention that Messrs. Dick, Kerr, and Co., who have just laid the permanent line at Northfleet, have recently issued an elaborate catalogue and descriptive list, plentifully illustrated and well bound, under the title "Tramway Materials." In this, we find some 40 sections of tramway rails, in full size, as kept in stock; illustrations of tramway points, wheels and carriages generally. Besides this, there are a number of interesting views from photographs, showing various tramways in course of formation, with views of power stations—in this case for cable machinery—soon, we hope, for electric machinery only; and steam locomotives, which will soon also make way everywhere for the electric engine. Tramways themselves, however, will continue to increase, and those who have anything to do with the construction of them should obtain a copy of Messrs. Dick, Kerr, and Co.'s book.

Storage Cars in Washington.—The Main electric car, controlled by the River and Rail Electric Company, of New York, has recently, says the American *Engineering News*, had a successful test in Washington, and is said to promise excellent service. The system uses only one motor instead of two, and the entire motive apparatus, storage batteries and all, weighs only some 4,000lb., it is stated, being much less than most other motors. The speed of the car was eight to twelve miles per hour. The mechanical connection between the motor and the sprocket-wheel driving-chains is exceedingly ingenious, novel, and compact. The motor is not stopped because the car is stopped, but continues in motion unless the stop is to be of some duration, and a change can also be made from high speed and low power to low speed and high power without any change in the motion of the motor. The storage batteries, likewise, are claimed to be a great advance on past practice, especially in respect to durability.

Suggested Electric Lighting for Dorchester.—An application was recently made to the Dorchester Gas Company by the Town Council for a reduction in the charge for the public lighting. The directors, in reply, reminded the Council that the terms of the contract of 1887 were approved of by the Corporation, and as the cost of producing gas is the same now as it was then, they could not see their way to making any alteration in the price. At the last meeting of the Town Council, Mr. George said he thought the company were pressing the Corporation very hard, because there was now in London a company who were willing to supply the electric light at a rate equivalent to 4s. per 1,000ft. of gas, and in Dorchester they were well situated for electric lighting, because water-power could be utilised. If the gas company pressed them too hard, it would be worth while to consider whether it would not be cheaper to introduce the electric light in Dorchester. After further discussion, it was resolved to apply to the electric light company in question to furnish an estimate for the supply of the light.

Electricity from Solar Energy.—Prof. Thornton Osmond, in America, has been making experiments with the idea of obtaining electric energy direct from the source of all terrestrial energy, solar heat. Should not, he asks, the rotation of the plane of polarisation produce magnetism? With a view of testing this, he constructed a polariser of thin sheets of glass, set in a tube at an angle of 35° 25' with the axis, to give a transmitted polarised beam 5 centimetres diameter. This tube was rotated and a beam of sunlight sent through it from a heliostat. Three coils from 18 to 63 centimetres long, wound with wire and fitted with soft iron tubular cores with glass ends, were filled with various gases, liquids, etc., to be traversed by the beam, whose plane of polarisation was being rotated. Several experiments were tried with an astatic needle placed in the rotating beam, and in two or three of the experiments there were traces of electric action. Prof. Osmond is intending to repeat these experiments at the Pennsylvania State College, and continue the research by other experiments with new apparatus. The details given are incomplete, but suggestive, and may lead to further results.

Catalogue of Electric Bells.—The seventh edition of the General Electric Co.'s Catalogue of Electric Bells has just been published. It is a book of some 50 pages, similar to their catalogue of electric light fittings lately noticed in these columns, and comprises practically every requisite that can be asked for in the working of electric bells. We see details of connections, with explanatory diagrams, for fitting up; illustrations of trembling bells and continuous bells; circular and bracket bells; bells with indicators; bells with pendulums; and bells with varied chimes. Indicators of all types and sizes are also shown, and electric bell sets with self-contained battery to suit all requirements. Pushes and door-pulls are shown in great variety to suit the decoration of houses, and switches, wires, batteries, screws, and fittings are all illustrated, besides alarms, galvanometers, lightning conductors, telephones, telegraphic instruments, and electro-medical appliances. The catalogue contains some 260 illustrations, and should prove exceedingly useful for the purchase of electric bell fittings in England and the colonies. Those of our readers who deal in this class of work should not fail to apply for a copy.

Law Courts Branch Bank.—It speaks well for the progress of electric lighting, when carefully installed, that the Bank of England after making very considerable tests have not only extended the light very largely throughout the Bank itself, but have authorised its introduction throughout the whole of the fine block of buildings which has recently been erected at the Law Courts. Messrs.

Digitized by Google

Drake and Gorham have now completed this work, which is giving every satisfaction, and the benefit of the light is already fully appreciated. The plant consists of a Crossley gas engine driving a 12-unit Elwell-Parker dynamo, which supplies current to 53 large D. and G. cells, manufactured by Elwell-Parker, Limited, and the total number of lamps fitted exceeds 200. Great care has been taken in dividing off the different portions of the plant, so that the exhaust pit, circulating tanks, and other sources of heat are completely separated from the engine and dynamo room, a very necessary precaution where ventilation is difficult. The current is distributed by one of Drake and Gorham's ring contact switchboards, which arranges for the regulation of both charging and discharging circuits and the measurement of the current in both dynamo and lamp circuits with one ammeter.

Electric Lighting in Algeria.—The central station recently opened at Milianah, Algeria, is an extremely interesting one. It has two Manchester dynamos driven by a Meunier turbine, and giving together 210 amperes at 110 volts. The station is established in a mill just outside the town; the main cable, 100 millimetres square in section, is about 550 yards long in one direction, and the distribution is effected to twice this distance. The public lighting at present consists of 40 lamps of 20 candles, 25 lamps of 50 candles, and several of 200, 300 and 500 candles at the principal crossings. All the town buildings are also lighted electrically. The installation was carried out by the firm of Feray, of Essonnes, at the cost of about £2,300. The maintenance, including depreciation and interest, is given at about £330 per annum, and the income from private customers is already £310 per annum. The public lighting, therefore, does not cost more than £20 a year, while the public lighting by oil had hitherto been almost £250 a year, besides not giving anything like the amount of light. The price of 20-c.p. incandescent lamps to private customers is 30s. a lamp a year. The success of the installation from the financial point of view is extremely satisfactory, and represents an example that might be largely imitated.

London County Council.—At the last meeting of the London County Council on Tuesday, held at the Council Chamber of the Guildhall, Mr. Beal moved: "That it be referred to the Finance Committee to consider the steps to be taken, if they so advise, as to acquiring the undertakings now supplying London with water and gas: as to the former, whether new sources of supply should be reported on by the engineers of the Council, and, if so, what time would be required for that purpose, having in view the report of several Royal Commissions; and, as to the latter, the recommendations essential as to the competition of electric supply; such report to be presented not later than June next, in order to permit the requisite notices to be considered, prepared, and given in November for the ensuing session, and that the requisite powers may be obtained by any Bill promoted this session by the Council." Mr. Æneas Smith seconded the motion. Capt. James moved as an amendment, "That in the opinion of this Council it is inexpedient to take into consideration the motion until sufficient time has elapsed for the Council to have thoroughly mastered the duties at present conferred on it." The amendment was negatived by a show of hands without discussion. Mr. Rhodes suggested that the question of gas should be omitted from the motion, and this Mr. Beal agreed to. After some discussion, the matter was referred to a special committee.

Telephonic Communication in Paris.—The Paris correspondent of the *Daily News* says: The Municipal Council has been discussing various proposals for improving telephone communication in Paris. The concession of the present company lapses on September 8, and whether it is renewed or not, the rates will be lowered and faster communication secured. At present the subscription in Paris is excessive, about £24 a year, whereas at Brussels it is only £10, and at Boston and Philadelphia £5. Paris has a smaller proportion of persons using telephones than most cities, except, I believe, London. The proportion here is about 1 to every 400 inhabitants; while in New York it is 1 to every 90. The complaints about the service in Paris have at length had some effect, the company having spent over £8,000 last month on improvements, on the chance of obtaining the renewal of its concession. Paris, however, is tired of monopolies, and the Corporation will not lose an opportunity of abolishing one. Among the most ingenious proposals is that of M. Leon Donnat, the municipal councillor and a leading economist, who would give the lease of the telephone system to the subscribers themselves, incorporated as a co-operative society. The rate would be reduced to £16 a year at the utmost, and in addition to this subscribers would benefit as part proprietors, while the city might gain by the increased exchanges.

The Continental Submarine Cables.—A news agency states that the representatives of the French and Belgian Telegraphs Department who were deputed by their respective Governments to discuss with the English officials the terms upon which the submarine cables between England and those countries should be taken over, have arrived at an agreement as to the price which shall be offered for the cables and plant. This was promptly communicated to the British Treasury, where the agreement arrived at was definitely approved, and an offer was immediately afterwards made to the Submarine Telegraph Company on behalf of the countries interested. The price which the three countries have agreed to pay is not so large as the directors of the Submarine Telegraph Company expected, but, on the other hand, it is far from being a confiscation price, which many of the shareholders anticipated. The amount will be announced in Parliament within a few days, immediately after the French and Belgian Governments have ratified the decision arrived at by their representatives. There is now not the slightest doubt that this will be done, and that the General Post Office will be in a position to take over the working of the submarine cables on the 1st April. The officials of the English Post Office are to be congratulated upon the skill which they have displayed in bringing this most difficult business to a successful issue.

Electric Central Station in New Zealand.—A proposal is on foot at Dunedin, Otago, New Zealand, for the formation of an electric power company to run the tramcars of that city, and to supply light and power to the neighbouring shops and houses. The comparative running expenses per mile on the different systems of traction were estimated by Mr. E. J. Foord, as follows: By horse, £1,936; by electric conduit, £1,006; by electric overhead, £665; by cable, £1,698. The proposed central station, site, buildings, boilers, and fittings were estimated at £15,165. This would provide for one car to carry 70 passengers, one to carry 32, and the 17 cars at present belonging to the tramway company, converted into cars electrically driven—making 19 cars available. It was also proposed to drive them four miles an hour faster than they

Digitized by Google

were at present, thus virtually increasing the plant by one-third. The expenses of working the trams by electricity would be £4,865, after making a liberal allowance in all cases. A saving was reckoned on of 2d. per mile, being equal to £2,750 per year. The revenue under the proposed system was estimated at £6,675. An alternative proposal was for a generating station at Green Island, where coal and water would be cheaper; and, further, 150 h.p. could be supplied to users at a profit. A committee was appointed to endeavour to carry the matter out, and obtain estimates. It is pleasing to us to see the English colonies are at last beginning to take up the question of electric traction practically, and we hope the proposed station in Dunedin will shortly become an accomplished fact.

The Metropolitan Electric Stations.—The work of dotting the vast area of London with 20,000 light stations, undertaken by the Metropolitan Electric Supply Company, is proceeding apace. They have now five or six stations either begun or actually contemplated. These stations will be on the alternating current transformer system, and each will have trunk lines connecting it to two other stations, so that even in event of total breakdown in any one station, the district would not suffer darkness. The only station which will not be so connected is the first, Whitehall Court, which is more or less a local and restricted supply station for Whitehall-mansions and a few neighbouring buildings. St. Martin's Church is lighted from this station, and also Messrs. Hampton's, in Pall-mall, besides the Avenue Theatre; and the Hotel Metropole and the Grand Hotel will be connected shortly, making a total of about 5,000 lamps, which is as much as this station will supply. This is on the low-tension direct current system, with accumulators. Number two (the first alternating station) will be Sardinia-street, Lincoln's-inn-fields, where building is now going on night and day, the wall rising at some 5ft. a day. The Westinghouse Company have the electric part of this station—which is for 25,000 lamps—entirely in their own hands. It will be a show plant, and they may be depended upon to do their best. The machinery is now nearly all in London, and ready to fix. The chimney shaft is some 12ft. square. The boilers, Babcock and Wilcox type (also ready) are to be placed below ground level, and the steam will be delivered upward to secure dry steam. The engine-house is in two storeys, lined with white bricks—Westinghouse engines on the ground floor, driving Westinghouse dynamos by belting on the floor above. Space is allowed for doubling the station, which will supply the central district from Holborn to Ludgate-hill and Fleet-street. The mains will be underground as far as possible. The third station is that known as Pritchetts, Rathbone-place, which has been bought as a going concern of 2,000 lights, Mr. Pritchett having accepted the position of managing engineer of the station. The Mordey alternators will be taken out and replaced by six 2,000-light alternating machines, made by Elwell-Parker, and driven by Willans engines. This plant is ready, and was, we believe, originally made for the House-to-House Company for sending to Australia, and has been bought up by the Metropolitan Company to equip this station at once. It is promised to be running by the end of May. The fourth station, Kapp dynamos made by Johnson and Phillips, is the Waterloo-wharf Station, not yet begun, although the machinery is in hand. The fifth is for Manchester-square, to supply the Duke-street and Marylebone district. Another station is also in contemplation for the Charing Cross district, for which drawings are completed, but the site is not yet settled. The work thus undertaken has meant the expenditure of £400,000, and the whole of these stations, it is expected, will be at work this year. Orders have been booked up to the present time for some 90,000 lamps.

Thomson-Houston System at Reading.—The electric light made its first appearance, by way of street lighting, in Reading, just after midnight on Friday, and the public opening took place on Saturday evening last, when thousands of people had congregated in the main thoroughfares to witness the demonstration. The installation has been carried out by Messrs. Laing, Wharton, and Down, who are under an agreement with the Corporation to light, by way of experiment and at the proposal of the firm, some of the principal thoroughfares for a month, the local authority undertaking to provide the poles to carry the wires and the lamps, and Messrs. Laing and Co. the current lamps, wire, and all other necessaries free of charge. The selection of the sites of the lamps was left to the Corporation. The depot at Reading is situate on what is known as the Island, in Duke-street, and the plant laid down consists of two 10 h.p. nominal engines, running at 380 revolutions, with steam at 110lb. These drive two Thomson-Houston H type dynamos, with 950 revolutions, and capable of supplying 18 1,200-c.p. arc lamps on a five mile circuit. The plant has been supplied in duplicate throughout, so as to prevent an extinction of the light in case of a breakdown, and a few seconds only are required to change the lamp circuit from one dynamo to the other. The switchboard allows one or other dynamo being connected to or taken off the lamp circuit whilst the lamps are alight. The boiler is one of the Babcock and Wilcox 25 h.p. water tubulars, which has amongst its principal advantages the continual circulation of water, the small consumption of coal, and the great rapidity with which steam can be got up—110lb. pressure can be obtained in 30 minutes. The boiler is fitted with a Worthington feed pump and a water purifier of improved construction. There are at present six arc lamps in the public streets, and two others for private users. Those in the streets are Thomson-Rice pattern, and the others are Thomson-Houston lamps, the latter being more suitable for indoor use. The carbons are Lacombe and Co.'s best cored, 12 millimetres, burning about 10 hours without trimming. The insulators are of Johnson and Phillips' fluid type, guaranteed to give higher insulation than those of any other make. The installation, at the opening on Saturday, suffered a little on account of the brightness of the night and the rising of the full moon. The lamps also were rather too high on the poles, and the opal glass globes did not allow of a full light. These drawbacks have since been remedied by the local manager, Mr. F. F. Yeatman. Now that the nights are darker the light shows brilliantly. The single lamp at present in the large space in front of the Municipal Buildings is not sufficient, and two or three will probably be required. The light is beautifully clear and steady, and is free from hissing. It is stated that 30 1,200-c.p. arc lamps would light the central part of the borough at a cost per lamp of about £22 a year. In other words, for an increased outlay of about one-third the present cost of lighting, ten times as much light would be guaranteed. The cost of the private lamps is £15 a year, inclusive of everything except £1 for fixing.

THE VICTOR TURBINE.

Now that the transmission of power by means of high-tension currents for considerable distances is a problem which electrical engineering has little difficulty or hesitation in undertaking, the question of a good and economical waterwheel becomes a point of just importance where advantage can be taken of natural sources of power. In France, in Germany, and in Switzerland examples are now not at all rare of small towns, or even fairly large ones, being lighted up with both arc and incandescent lights in their public streets, and with a supply of current for several hundreds or thousands of incandescent lights for private houses, the power being obtained from

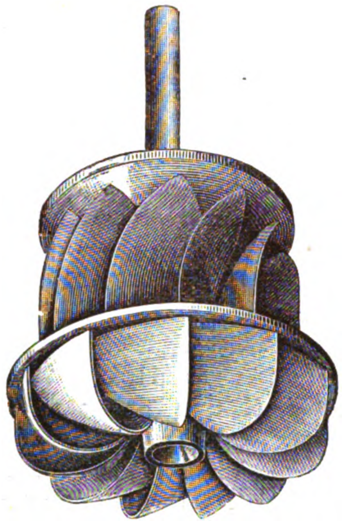

Fig. 1. Victor Turbine Removed from its Case.

a fall of water, sometimes at distances of some miles from the point of distribution. Without arguing that England in this respect should be as well off as other countries in instances of this kind, there are, without doubt, many places where the water-power now running to waste could be made, by means of high-tension

of turbine, in that it receives the water upon the outside, and discharges it downwards and outwards (in the vertical form of turbine), the lines of discharge occupying the whole

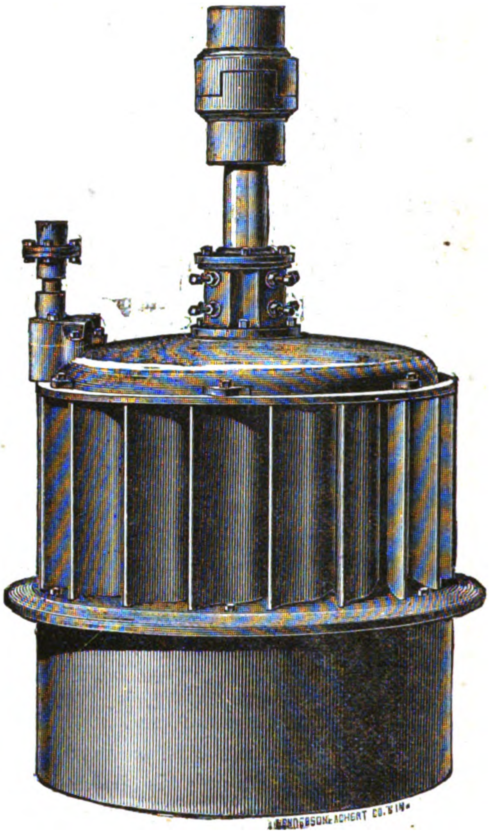

Fig. 2. Victor Turbine and Case complete.

diameter of the lower portion, with the exception of the shaft itself (see Fig. 1). This construction gives a maximum capacity for a given diameter, and the tests which have been made officially in competition with other makes in America showed some very remarkable results. The 15in. Victor turbine, under 18·34ft. head, actually gave

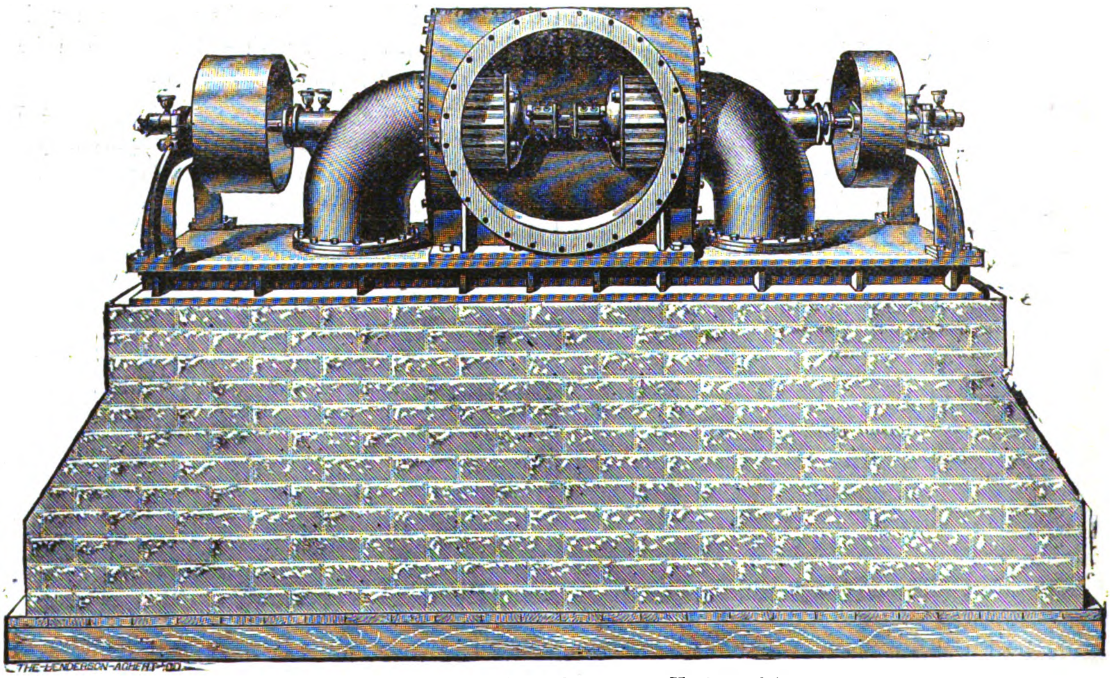

Fig. 3. Pair of 12in. Victor Turbines on Horizontal Shaft.

transmission, to supply light and power to neighbouring districts with economy.

For the development of water power the Victor turbine has proved itself satisfactory in all parts of the world, giving a very high return of the theoretical power available, and we illustrate herewith some examples of its appearance and application in actual work. The Victor turbine is different in construction from most forms

29·36 h.p., at an efficiency of 88·08 per cent. This size of turbine by other makers is tabled to give from 8 to 15 h.p., and the saving both in outlay and in carriage with the more capable wheel can be easily realised. The efficiency, also, is extremely high, very few turbines being able to reach much over 70 per cent. efficiency, while the official tests of the Victor turbine show efficiencies of 89·60 per cent. for the best test

Digitized by Google

of a $17\frac{1}{2}$in. wheel, and 82·89 per cent. for the lowest efficiency of a 35in. wheel. Proportionately high results were obtained at partial gate with the various sizes.

In construction, all parts of the Victor turbine are bored and turned by machinery, every part being fitted to standard

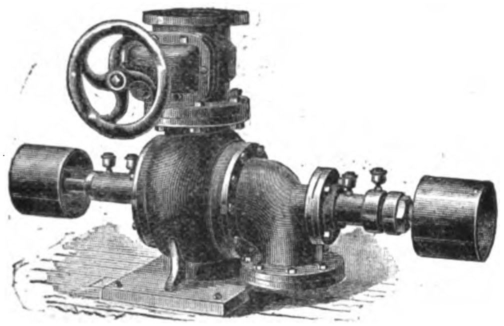

FIG. 4. 5in. Victor Turbine for High Falls.

gauge, and duplicate parts can be furnished in case of accident. The fitting together is simple, and facilities are provided for taking up the wear without removal. Provision is also made for perfect lubrication.

on horizontal shaft, with flume fitted in one piece, as shown in Fig 4. The wheel in this case is made of gunmetal, and the discharge and supply pipes are both of 5in. diameter.

One of the recent applications of these turbines is that shown in our last illustration, which represents the power-house of the Clifton Manufacturing Company, Clifton, South Carolina. A portion of the wheelhouse is broken away to show the waterwheel plant, consisting of two pairs of 48-in. Victor turbines on horizontal shaft, working under an 18ft. head, and capable of developing 980 h.p. This plant drives the whole of the machinery of the factory, and also supplies light for the adjacent buildings by means of dynamos.

For regulation, the turbine is fitted with a register-gate, which is moved by a segment and pinion, or can be controlled by a governor. The movement of this register-gate regulates the amount of water supply without changing the direction of the current or the relative angle of the stream with the blades, and without in any degree checking the velocity of the water admitted.

Mr. Frederic Nell, of 16, Mark-lane, London, for whom these turbines are built, has issued tables from which the water-power of various falls can be calculated ; and in order to effectually fulfil stipulated requirements, will agree to specify in the contracts undertaken the actual horse-power delivered under given head with stated quantity of water, and will also advise or superintend the installation of water-power installations.

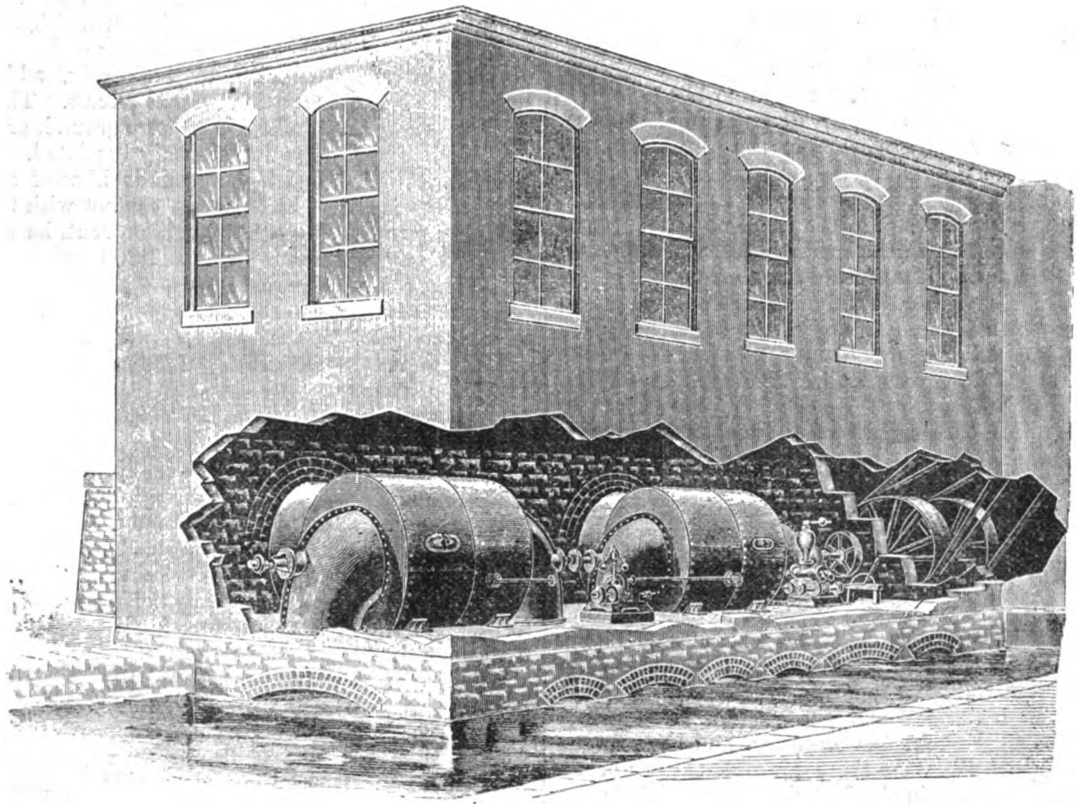

FIG. 5. Victor Turbines, 980 h.p., at Clifton, South Carolina, U.S.

The appearance of the Victor turbine in its case complete, as sent out ready to set in the flume, is shown in the illustration, Fig. 2. The water is received above from the outside, and is discharged inside the bottom casing, rotating the shaft at a high rate of speed. The shaft can be directly connected to gearing, or be furnished with clutch, as shown.

For electric lighting it is often more suitable to take the power from the shaft of the turbine by means of pulleys and belts direct to the dynamos, and for such cases a horizontal form of turbine is constructed. In many instances a pair of horizontal turbines are connected together on one shaft, and served from one water flume. This arrangement is shown in Fig. 3, which illustrates a pair of 12in. turbines, with bearings and pulleys complete, on foundation, constructed to operate under 46ft. head. This pair of wheels was constructed for an electric light company, and a similar arrangement has been furnished to drive the huge dynamos of the Cowles Electric Smelting and Aluminum Company, where a pair of 30in. turbines, under 35ft. head, furnish 528 h.p. with great satisfaction.

For special circumstances where a high fall and small quantity of water is available, a 5in. turbine is constructed

ELECTRIC LIGHTING OF THEATRES.—V.

ADELPHI THEATRE.

This theatre possesses a very fine and most complete installation of the electric light. The front of the house, auditorium, stage, dressing-rooms, etc., are all lighted electrically, and there is not a single gas-jet in the building. Danger from fire is not only guarded against by banishing gas, but also by laying the electric light leads on an incombustible principle. Virtue is sometimes its own and sole reward; but in this case Messrs. Gatti's prudence is rewarded by a very substantial diminution in the insurance rate as well. The Adelphi Theatre, Adelphi Restaurant, and the Adelaide Gallery Restaurant, of Messrs. Gatti, are all lighted from a little station of their own in Bull-

Digitized by Google

inn-court. This station has a lighting capacity of 5,000 incandescent lamps of 16 c.p. each; and, as Messrs. Gatti only require light equivalent to about 3,200 16-c.p. lamps themselves, they contemplate doing some lighting in other buildings in the neighbourhood, and already light the Peacock Inn with about 100 lamps.

Their station is fitted throughout with most excellent machines and accessories, and is very well arranged for easy management. The plant consists of three boilers of the well-known Babcock and Wilcox type, each of 156 h.p.; two large and one small centrifugal steam separators, with Tangye's feed-water pumps, and also an exhaust steam injector. The engines are by Willans and Robinson—two of 130 h.p. each, and two of 75 h.p. each. Four dynamos of the Edison-Hopkinson type (shunt-wound machines) are driven direct by the Willans engines; the two larger dynamos give a maximum current of 800 amperes each at 425 revolutions per minute, and the two smaller a maximum current of 475 amperes each at 450 revolutions per minute. Each of the dynamos has a small flywheel to ensure the absolute steadiness of the lights. One large and one small engine and dynamo do the lighting, and the remaining two are spare sets in case of accident. The voltmeters employed in the engine-room are of the Schuckert type, and the resistances are of iron wire spirals. The leads from the four dynamos are taken to two large switchboards, which are arranged very much after the fashion of a telephone exchange switchboard. By the one switchboard the whole load of a dynamo and its engine can be transferred to its fellow dynamo and engine, and by the other any part of the load can be transferred from any dynamo to any other. When a dynamo is going to be put on in place of its fellow, it is brought up on resistance to give the required current, and then plugs are so put in on the switchboard that the turning of a handle transfers the fresh dynamo from the resistance to the lamps, and the other dynamo from the lamps to the resistance, so that there is no interruption (nor even flickering, as we had the opportunity to observe) of the lighting. From these two switchboards the cables are led to the theatre switchboard at the side of the stage, and to the two restaurants. The whole of the theatre lighting is controlled from the stage switchboard. The cables are of the best quality throughout, and very great precautions have been taken with the whole of the wiring. The copper is first well insulated in the ordinary way, and then coated with asbestos. The asbestos-covered leads are drawn into iron pipes of the required sizes, and then laid in wood casing as usual.

The front of the house is lighted by about 250 16-c.p. lamps, arranged for the most part singly. The auditorium is lighted by eight Sunbeam lamps of 200 c.p. each, which are arranged in a circle round the dome. These give a very good light throughout the auditory, and have a very pleasing effect. On the stage there are four battens of 85 white lights in each, and in the float three rows of 60 lamps in each row. The first row consists of white lights, the second of red, and the third of blue, so that the sunset and moonlight effects are produced without mediums. In the dressing-rooms there are 105 16-c.p. lamps, and in the basement 68 16-c.p. lamps.

The possibility of being able to completely extinguish the lights on the stage and in the auditorium is employed in this theatre for the changing of scenes without the lowering of the curtain. Thus, when a very great change is not required, these lights are turned off, the scene changes, and the lights are turned on again.

The management of this theatre experience all the advantages we have enumerated in previous articles as consequent on the substitution of electric for gas lighting; but we may mention that in their case the reduction in the insurance rate is very great—viz., from £2. 2s. to £1. 5s. per £1,000, or about 40 per cent. diminution. The relative cost, taking account of the interest on the capital sunk, depreciation, repairs, etc., they find to be slightly greater than with gas, but as set-off to this they have more light, and no doubt when their plant is worked to something near its real capacity they will find the balance of cost the other way. Out of every three lamps together, two are on the circuit of one dynamo, and the third on that of the other running dynamo, so that there is no possibility of any part of the building being plunged into total darkness by any breakdown of an engine or dynamo, etc. We may conclude by repeating that the general installation, plant, and fittings are all excellent, and on a very good—carefully designed and well carried out—system, which reflects the greatest credit on all concerned with it.

The whole of the works have been carried out under the superintendence of Mr. Spencer Chadwick, architect, of 17, Parliament-street, Westminster.

STANDARD OF INSULATION FOR ELECTRIC LIGHT CIRCUITS.

BY G. E. FISH.

In establishing a standard insulation for electric light circuits three questions are to be considered. The first and most important is to guard against danger to human life; second, to guard against fire; and third, the cost of maintaining this standard. Ohm's law shows that the quantity of electricity passing through a conductor is equal in amperes to the E.M.F. in volts divided by the resistance of the conductor in ohms. If a man comes in contact with the conductor of an arc or incandescent circuit, a current will pass through him which will be equal to the E.M.F. of the current passing through the conductor divided by the resistance of his body, added to the resistance of the insulation of the circuit. This assumes that the man is standing on damp ground, or is in some position in which he is not perfectly insulated. If one terminal is grounded, and if he grounds himself at the other terminal at the time he comes in contact with the conductor, which is carrying a 1,000-volt current, he will receive in his body current equal to 1,000 volts, divided by 5,000 ohms or ·2 ampere.

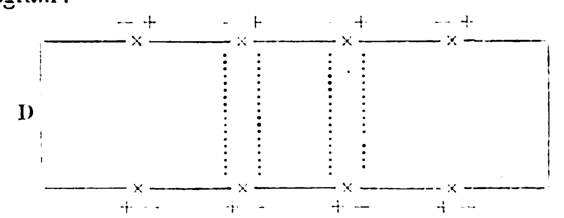
I have measured the resistance of several men from hand to hand, and find that they average from 4,000 to 15,000 ohms. As it is a generally accepted fact that 1,000 volts will kill a man, and assuming from the above test that the average resistance of the human body is 5,000 ohms, we get by Ohm's law $\frac{1,000}{5,000} = \cdot 2$ ampere, which would go to show that the quantity of current that will destroy human life is two-tenths of an ampere.

A gentleman who is well informed in electrical science claims that one-tenth of an ampere is all that is required but I once had an opportunity of disproving the statement. An employé was connecting a testing device to be used on a dynamo that at the time was running with 32 arc lights. The potential had been taken a few moments before, and was found to be 1,300 volts. The device was to be shunted across the terminals of the dynamo. At the time one side of it was connected, a short wire was hanging from the other side. The man was at work on a wire from the opposite terminal of the dynamo when he accidentally touched the end of the free wire, receiving through his body the 1,300 volts. The resistance of the testing device was 5,580 ohms, and of his body, from hand to hand, 6,000, so that he got a current equal to these two resistances added (11,580 ohms), divided into the 1,300 volts, or ·12 ampere. Had not the 5,580 ohms' resistance been between him and the opposite pole of the dynamo, there is no question but that he would have been killed. In that case he would have received $\frac{1,300}{6,000} = \cdot 21$ ampere.

Assuming that ·2 ampere is the quantity of current we must provide against, let us determine on an insulation. For example, we will take a circuit of 50 arc lights and a current of 2,500 volts, the insulation of the circuit measuring infinity, except at a point at the negative pole, where it is a megohm. If a man comes in contact with the conductor at the positive pole, a current will pass through him equal to $\frac{2,500}{1,000,000 + 5,000} = \cdot 0024$ of an ampere.

Let us now assume that the insulation of the circuit is a megohm equally distributed. We have 50 lamps with a potential of 2,500 volts, or 50 volts to the lamp, and a total

insulation of 1,000,000 ohms, or 50,000,000 ohms to each space between lamps. There will be a certain amount of leakage from each of these spaces, as shown in the diagram:



The dotted lines represent the leakage. The insulation from one lamp to another is $\frac{50,000,000}{2}$, or 25,000,000, and, with a potential of 100 volts (two lamps), we have a leakage or "eddy current" of $\frac{100}{25,000,000}$ = ·00004 of an ampere.

The man of 5,000 ohms' resistance comes in contact with the conductor at some point along the circuit, forming a shunt of $\frac{50,000,000 \times 5,000}{50,000,000 + 5,000} = 4,997$ ohms. Now, as he has only shunted one side of the circuit, he will get a current in proportion to the resistance of the other side, and the current will be equal to $\frac{50,000,000 \times 9,997}{50,000,000 + 9,997} = \frac{100}{4,996}$ = ·02 of an ampere, which is not at all dangerous.

Let us now assume that the circuit measures infinity, except at a point near one terminal, where it is 12,500. If he comes in contact with it at the opposite pole, he will receive a current of $\frac{2,500}{12,500 + 5,000}$ = ·14 of an ampere, which, while perhaps not dangerous, would be very uncomfortable.

If we distribute the 12,500 ohms equally, as in the case of the megohm circuits, we get 12,500 × 50 = 625,000 as the insulation of each space, which, divided by two, gives us 312,500 as a path for 100 volts, or a current of ·00032 of an ampere. From this we may assume that an insulation of 12,500 ohms equally distributed is perfectly safe for a 50-light circuit, so far as any danger to life is concerned, and we may settle upon an insulation of five times the E.M.F. as a standard. As an example of the employment of this rule, let us take the following: a 20-light arc circuit, 45-volt lamps, 20 × 45 × 5 = 4,500; $\frac{900}{4,500 + 5,000}$ = ·095 ampere, which we have shown is perfectly safe. Or we will take an incandescent circuit of 220 volts; 220 × 5 = 1,200; $\frac{220}{1,200 + 5,000}$ = ·037 of an ampere.

As to the fire question, let us first determine what causes the fire. If the wire used is of the same size as that at present employed there can be no danger of its becoming heated, so we must look to the insulation. If the current could not leak from the wire there would be no danger, but it does get away, and it escapes through the defective insulation. It is my opinion that the fire is caused by the current heating this defective insulation as it passes through it, and that heating will be in proportion to the amount of current flowing through it. For instance, if a current becomes "dead" grounded on one side, there is no danger, except that of forming another ground or an escape between the ground and the point of lowest insulation, which escape will be in proportion to the E.M.F. between those two points. Now, suppose another ground does come in; so long as neither of them offers any resistance there can be no danger, but if instead of a ground it is an escape of 500 ohms, and the potential is 2,000 volts, there will flow through this escape a current of $\frac{2,000}{500}$ = 4 amperes. If the material through which it is flowing is of an inflammable nature it is more than likely it will be ignited, or will heat sufficiently to ignite surrounding matter. Let there be two weak spots of 500 ohms each, with a potential of 2,000 volts between them, and we have $\frac{2,000}{1,000}$ = 2 amperes, which, for aught we know, may be sufficient to cause fire.

From a practical experience of eight years, I should say that an insulation of 10,000 ohms ought to be sufficient for a 50-light arc circuit, as that would permit of a leakage of but ·2 ampere with the 10,000 ohms between the points of highest potential, and this quantity of current would be very unlikely to cause fire, although it might slightly injure the insulation at that point. In view of these facts, I have always made it a point never to run a circuit on less than 10,000 ohms, unless it was a dead ground.

Although I have always held to this rule of never starting a circuit on less than 10,000 ohms, there have been occasions when the insulation dropped below that point after starting, and it has burned out at the weak point. Of course, we have no way as yet of telling when an insulation drops below a certain point after the circuit has started, but I expect before long we will be provided with a device that will indicate this.

Now, to consider the cost of maintaining the standard of insulation. We see from the foregoing that 10,000 ohms is safe, so far as any danger to life or from fire is concerned, but the question arises, is that an economical insulation for us? I shall say no, but perhaps I cannot tell why any more than an engineer can explain why it is easier to keep his steam at 80lb. than to let it fall to 75lb. and then get it back to 80lb. Our 80lb. is a megohm. Let the insulation drop below that and it is hard work to get it back again. As a cause for this let us again refer to the 50-light circuit of 2,000 volts, and an insulation of 100,000, equally distributed. This gives us 100,000 × 50 = 5,000,000, the insulation of each space between lamps; $\frac{5,000,000}{2}$ = 2,500,000, the resistance to be overcome by the leak or eddy current. Two lamps of 40 volts each would make this leakage $\frac{80}{2,500,000}$ = 0·000032 of an ampere, a very small quantity, but there are 25 groups of these leaks, the total of which is $\frac{2,000}{100,000}$ = 0·02 of an ampere, and this 0·02 of an ampere is constantly straining to enlarge itself. With the insulation of the circuit at 10,000 we would have 10,000 × 50 = 500,000 ohms to each lamp space. This, divided by two, gives us 250,000 as the path for the leak, and $\frac{80}{250,000}$ = ·0003 as the quantity of current flowing through that leak, and with the 25 groups we have $\frac{2,000}{10,000}$ = ·2 of an ampere; quite an amount of current. With the circuit at a megohm, and following up the same computations, we get but ·002 of an ampere as the amount of leakage, which is so small as to be of no consequence.

From all facts, we may come to the following conclusions:

1. That if the insulation of a circuit at the lowest point is five times the E.M.F., there will be no danger to human life.

2. That we may consider 10,000 ohms a safe insulation for a 50-light circuit, so far as any danger from fire is concerned.

3. That we find in practice that the higher our insulation, the more economical it is for us to maintain the circuits in running order, and that it is to our interest to keep the insulation as high as possible at all times.

Therefore, in establishing a standard insulation for electric light circuits, why not place it at five times the E.M.F., which, on an arc circuit of 1,000 volts, would permit of a leakage of but ·2 of an ampere—$\frac{1,000}{5,000}$ = ·2—and on an incandescent circuit of 220 volts ·1 of an ampere.—*Western Electrician.*

Papers.—Next Thursday, at the Institution of Electrical Engineers, the following papers will be read: (1) "Laboratory Notes," by Profs. Ayrton and Perry; (2) "On the Disturbances Arising from the Use of Earth for Electric Lighting Purposes," by W. H. Preece, dealing with the earthing of 10,000-volt conductors and others.

City Lighting.—The specifications and forms of tender for the public lighting of the City of London have at last been definitely settled, and will be ready to issue, we understand, next week by Colonel Heywood, from the office of the Commissioner of Sewers at the Guildhall.

BOUND VOLUMES.

Vols. I. and II., new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

NOTICE.

During the course of the past year we issued steel engraved portraits of MR. E. GRAVES, *the then President, and now the immediate Past-President of the Institution of Electrical Engineers, also of* W. H. WOLLASTON, M.D., F.R.S., *and* SIR HUMPHRY DAVY, F.R.S. *The portraits of* PROF. D. E. HUGHES, F.R.S., *and of* DR. J. HOPKINSON, F.R.S., *are engraved, and will be issued in due course. Other engravings are in preparation.*

EXAMINATIONS.

Readers need not be afraid—it is no old parrot cry of schools, colleges, and examinations to which we desire to direct attention, but a brand-new importation from America. Of course it is another bugbear. Anything more in the shape of an examination must necessarily be so, but the question arises, is such an examination a necessity? Let us first see to what the examination refers. In America, just as in England, there have been squabbles between the insurance offices and electric lighting contractors. The offices were asked in the ordinary way to accept certain risks. Upon examining into matters, they found the risk would be all right if the workmanship was all right. Whenever anything went wrong, it was mostly traceable to bad workmanship, and in order to improve matters an exchange was started, one of the fundamental objects of which was to ensure good work.

Before pursuing this further, we may say that, according to the paper and discussion at the recent convention meeting in America, there is a risk, that of central stations, the insurance companies of America show no particular anxiety to accept. The reason given is that the central stations are mostly installed in unsuitable premises. We are glad that the tendency in England is quite different from this, and is to build or make the central station premises suitable for the work to be carried out therein.

To resume. There are certain classes of workmen engaged upon light and power installations whose carelessness or ignorance will certainly lead to troubles of various kinds. It may be only the breaking of lamps or the burning up of an armature, or it may be a serious and costly fire. The linesman or wireman is an important factor in the safety of an installation, and we have no hesitation in saying that some of these gentlemen are responsible for work carried out in London that would be a disgrace to a Hottentot, and for which they deserve incarceration in one of Her Majesty's prisons "during the term of their natural lives." Hardly any punishment is adequate as a deterrent to this kind of bad workmanship. The result may lead to frightful death, hence the condemnation of such practices cannot be too strong. Honourable firms do not countenance such things. They will not accept an offer which necessitates bad workmanship at the price. It is useless for people to argue that good "wiring" can be done at, say, ten shillings a lamp. It cannot, and though actual work done at and under this price may be quoted authoritatively against our dictum, we still retain our opinion, and trust to time to prove its correctness. Trouble arises from the workman or from the master. Assuming that the latter is not to blame, it becomes well worth consideration how far the action taken

Digitized by Google

in America might be adopted here to ensure good work. The motive power for action there came from the insurance companies, as will be seen from the following extract from a notice of the Boston Fire Underwriters' Union: "At a meeting of the Underwriters' Committee, held January 28th, 1889, it was voted that, on and after May 1st, 1889, all electric lighting and wiring companies' men who are in any way responsible for any of the wiring, running of the dynamos, or care and management of batteries for electric lighting, must hold a license from the N. E. Electric Exchange. This rule applies to isolated plants and central stations alike, and is imperative. No exceptions will be made." This is pretty strong, and shows at any rate that the insurance companies will not be bamboozled if they can help it. They insist upon the employment of competent men, and if the work is not then carried out satisfactorily, the cause is obvious—gross carelessness or neglect. If this question is worth discussing at all in England, the initiative must come from either (1) the Institution of Electrical Engineers, or (2) the Electrical Section of the Chamber of Commerce. The subject, being a purely commercial one, is hardly fit for the Institution, while it seems just one of those which ought to commend itself to the Chamber of Commerce. There is no doubt bad workmanship, leading to failure, is always more detrimental to the prosperity of a young industry than to an old one. In the latter, firms have obtained a reputation, and it is a recognised fact that orders may confidentially be placed in their hands, while a keener supervision is kept over the work of younger firms. In a young industry all firms are more or less young together, and time has not classified them into good, bad, and indifferent, but from the very first some firms commence to stand out above others as scorning to pass bad work, and refusing to accept orders that cannot be executed satisfactorily to both parties. Of course, you may pay too much for good work, but it is always better to pay a fair price rather than a conspicuously low one. We are rather inclined to believe that examination will not be a satisfactory solution of good workmanship and competency, unless there is included an examination into "honesty." A man may be quite able to do good work, yet have no intention of so doing, and how will examination meet such a difficulty? Inspection would be as much needed under such a system as now, and no one will dispute that inspectors ought to be thoroughly competent at all points. They should not only know how, but be able to actually do the work, otherwise inspection is a sham; for books will tell you how a thing should be done, while the practical man will describe such a description as foolish and impossible. The theorist always has at command "ifs" and "assumptions," none of which lend themselves to the requirements of the practical worker. Thus we contend the inspector should be able to do, rather than say how to do. Here again the section of the Chamber of Commerce might well formulate an opinion.

THE THOMSON ELECTRIC METER.

Among the list of practical working electric meters lately discussed by Prof. Forbes, there is one of considerable interest of which no mention has yet been made. This is the Thomson meter, now used in great numbers by the Thomson-Houston Company of America for incandescent lighting on their alternate-current circuits.

The accompanying diagram illustrates the construction of the Thomson meter, in which the indication of current measurement is brought about by a reciprocating action depending upon the alternate expansion of air in two bulbs, and the consequent displacement of liquid, caused by the heating of wire resistances inserted in those bulbs.

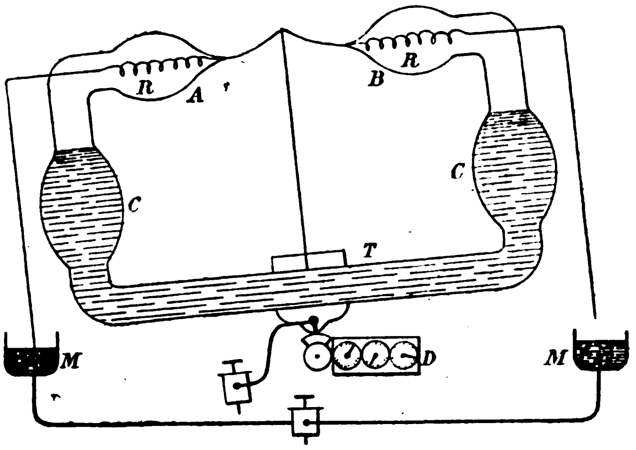

Diagram of Thomson-Houston Meter.

In the diagram, A and B are two bulbs connected together by a tube (T); the tube has also two bulbs blown in it, C, C, which are filled with kerosene oil. In the upper bulbs are small metal resistances, R, R, the inner ends of each being connected to one terminal, while the outer ends turn over and dip into two mercury cups, M, M. The glass tube is pivoted at its centre, and whichever way the tube tips, electric connection is made on that side with the mercury in the cup, through the resistance, R, contained in the bulb on the same side. The two mercury cups are connected to the other terminal.

The action is as follows: the current, or that portion of it shunted to the meter, heats the resistance; this expands the air in the bulb and forces some of the oil to the opposite side. The tube then rocks over, breaking the contact upon one side and making it on the other, when the same action is repeated. The rocker is connected to a train of wheels, and registers like the usual dial of a gas-meter. The meter is cheap and simple, and is said to have proved extremely satisfactory, and large quantities are being turned out at the factory of the Thomson-Houston Company, at Lynn, U.S.

NATIONAL ELECTRIC LIGHT ASSOCIATION (AMERICA)—MEETING AT CHICAGO.

(Continued from page 212.)

A paper was read by Mr. S. E. Barton on "Electric Light Stations as Fire Risks," which, while containing much of local interest, has some points of general interest. The writer contended that it was mutually advantageous for electric light contractors and insurance companies to work harmoniously. Of the former he said:

"Your duty is obviously to do all you can by your own work to promote and secure safety, and to encourage all feasible plans and efforts of others tending in the same direction. While the plain duty of underwriters in the public interest is first to hold to a strict line

Digitized by Google

of requirements any of you who may be tempted or compelled, through competitive pressure, to depart from what you know are safe practices; and, having done that, the underwriters' duty is not fulfilled until they have endorsed electrical illumination and power by the reduced premium charges that such combined action on the part of electrical and insurance interests is sure to warrant. The two interests are peculiarly identical. Hand in hand they can accomplish much in reducing the enormous fire waste. Disunited and antagonistic to each other, your work will be slower in development. Competition among yourselves, and no restraining supervision on our part, will drive you to cheaper construction and maintenance of your work. More fire loss and higher premiums for insurance must inevitably be the result, while the public, still calling for your light because it is good, will be deterred to an injurious degree by reason of the increased insurance rates that will surely follow, such as have already been applied in some cases, and threatened in others. The policy of insurance companies and organisations toward electric lighting, or any hazard, in fact, capable of being minimised, should not be 'to fit the punishment to the crime,' but rather to lessen the crime, or endeavour to."

A reduction of tariff is made in some risks lighted electrically by New England insurance companies. The agent of the companies in his endeavours to get business is an advocate for such lighting, and so works for contractors. By reason of faulty work which crept in during the early stages of electric lighting at Boston, numerous small fires occurred which led to the insurance companies insisting that the responsible men in installations should hold licenses from the New England Electric Exchange.

"In regard to the electric light generating station, the situation is not a pleasing one to either party. Out of over 200 fire insurance companies doing business in Massachusetts, the electric light station is a prohibited risk with all but about 25 or 30 of them. The reasons for this interdiction are chiefly these: First, because electrical apparatus, and dynamos in particular, have been found to be very susceptible to large and uncertain damage in cases of small fires; secondly, because generating stations have too frequently been crowded into very hazardous and improper quarters, simply to get floor space and power at the smallest cost, without regard to permanency and ultimate results; lastly and mainly, because insurance men, as a rule, do not understand the nature of the hazard and often fail to get enlightenment from those in charge of stations. Therefore a large majority of the companies adopt the course of all wise underwriters—they 'take the benefit of the doubt' and leave your station risks alone."

In the discussion, Mr. Morrison agreed as to the "lamentable condition of many of the electric light stations." Mr. Barton again was touched to the heart to see what he believed to be one of the safest classes of risk "in such a condition that insurance companies will not touch it as a general rule." This seems to have been the moral of the paper. Central stations are so badly installed in America that they can with difficulty be insured. In continuation of this subject, Mr. Alexander submitted a verbal report of the "Committee on the New England Electric Exchange," an organisation designed, in March last year, to be "a mediator between what seemed then to be conflicting interests." Manufacturers, electrical engineers, and those engaged commercially were eligible as members. "The prime object always has been to look for good work. Manufacturing companies and operating companies alike had a common interest to have good work done." As has been stated above, one outcome of the exchange has been to license wirers and linemen, those in charge of dynamos, etc.

"In order to promote ambition in excellence of workmanship, and to extend the knowledge among men practically engaged in installing and operating electrical plants, and thus make it an object for fire underwriters to recommend the introduction of electricity in preference to other means of producing artificial light and power, the New England Electric Exchange will issue licenses of five classes, each class representing a certain extent of qualification. First-class licenses are issued only to persons fully competent to install and operate any electric light or electric power plant. The applicant for a first-class license must be able to make working plans for central stations and for isolated installations; must have a general knowledge of the construction of dynamo electric machines and the electrical appliances necessary for electric light and electric power installations, a general knowledge of the principles, the construction, and installation of primary and storage batteries, a thorough knowledge of the insurance rules pertaining to the business, a specific knowledge of the systems operated by the applicant, and a thorough knowledge of the calculations necessary for and the rules governing electric wiring, and be able to make complete wiring plans. From this class we go down to those requiring less and less knowledge, to men who are not competent to do electric work. Fifth-class licenses are issued to persons competent only to operate electric machinery, and who are not competent to do electric wiring. The applicant for a fifth-class license must have a general knowledge of the operation of the particular electric light or electric power machinery it is desired to operate, and a thorough knowledge of the insurance rules pertaining thereto. You can readily see what great difficulty we have in examining these different men all over the New England States. We arranged for examinations weekly in Boston, but it was a very difficult thing to bring the men there, especially as they were not forced to go there at first under insurance rules. We found a great many very eager to take advantage of this, and very eager to know exactly themselves how much knowledge they did possess, and rightly so. It was often questioned, 'Who are your examiners, and who examined your examiners,' as one man put it to me. Well, we have in New England a good many good electrical men. We had Prof. Anthony and Mr. Hill, of Boston, on practical work. We generally take three men to work together, two of whom would be good practical men, and one having a good knowledge of theory. These gentlemen have to serve right along, without pay. I want to say, that in order to make this a success, it was necessary for about 25 of us to give half a day each week to this business exclusively—to devote themselves to this matter at the loss of their own business; but they have done it; we have found men who have done it. We have now six examining boards, composed of three each, and we have five on the directing board that meets every Monday. Every safeguard was put, however, around the issuing of licenses. These examiners would examine the applicant who made application for a certain class. How few of them attained it the last official report, which dates now some months back, will show. I find that 43 men applied for first-class licenses, and only 26 obtained it. Of 45 who applied for second class, only 31 were successful, while 42 men who had applied for higher class licenses received only a fourth class. But they were quite satisfied, and we have a great many letters from them saying, 'Why, we simply go ahead and will try again.' They have a right to come again and again for examination. They have, in several cases, brought to the second examination a great deal more knowledge than they ever had, putting their whole heart into it now, having something to look forward to and to attain. They have done very well; the plan has worked well, and the men themselves have done very well. After the examiners have gone through and made their minutes of the examination, they send their report to the board of directors, who weigh that matter carefully, and either send the report back, if not in accordance with rules laid down here, or accept it. Then, before issuing these licenses, each examiner has to sign the certificate that is issued; the president and secretary have to sign the certificate; and then once more we send it to the insurance inspector of that district, who comes in personal contact with these men, and who can tell us, although they may have a knowledge of the business, the men may be careless in carrying out their work. We have also a clause by which we can revoke any license that has been given to a man who proves incompetent afterwards, or careless in his work. We have found that men perfectly able to operate electric machinery are incompetent by reason of neglect and carelessness."

In the discussion, Capt. Brophy pointed out that good reliable work meant a less number of insurance inspectors.

(*To be continued.*)

ARC LAMPS AND THEIR MECHANISM.*

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

(*Continued from page 213*).

Experiments show that the special forms of electromagnet may be tabulated as follows:

(*a*) *Short-range Magnets.*—1. Horseshoe form, if constructed with short thick cores, thick yoke and thick armature, giving compact magnetic circuit.

2. "Pot-magnet," straight core with external tubular envelope, connected by iron at bottom. Armature, a stout iron disc or lid.

(*b*) *Moderate-range Magnets.*—1. Horseshoe form with long thin cores and armature, giving a non-compact circuit

2. Solenoid having a short fixed core extending part of the way down, and a second movable core to be attracted in as plunger. The name "stopped solenoid" is suggested as appropriate for this form.

3. Two such as last, having a yoke connecting the two fixed cores, and a second yoke connecting movable cores.

4. Stopped solenoid with plunger attached to an outer mantle (Kennedy's lamp, Fig. 10).

5. Electromagnet with conical poles protruding through hollow in armature (Thomson-Houston lamps, Figs. 14 and 25).

6. Electromagnets with oblique approach of armature. (Serrin's, Fig. 5; De Puydt's, Fig. 23; and many other lamps)

(*c*). *Long-range Magnets.*—1. Solenoid, cylindrical, with longer cylindrical core. Attraction greatest when entrant end of core just reaches the further side.

2. Solenoid, cylindrical, with long coned core entering with the point foremost.

3. Solenoid, conical, with long cylindrical core entering the thicker end of solenoid.

4. Special device for travel of unlimited length. A solenoid constructed in sections, which are switched into circuit progressively ahead of the core as the core travels down (Thomas, 578^{82}; Lindemann, 16376^{87}).†

It must be borne in mind that the range of an electromagnet depends on the relative dispositions of the iron parts of the magnetic circuit and of the magnetising copper parts, and in no way upon the question whether the coil consists of a few turns of thick wire, or of many turns of thin wire.

EQUALISERS.

In sundry forms of lamp special mechanical devices have been introduced for the purpose of equalising, throughout a given range of motion, the otherwise very unequal pull of the electromagnet upon its armature. Set-up springs with adjustable stops have been used for this purpose. A more satisfactory *equaliser* (*repartiteur*) is the device suggested by the famous conjurer, Robert Houdin, which is depicted in Fig. 1. Here the attraction of the electromagnet, E, for its armature, *a*, is transmitted through a system of two curved levers, A and B,

* Paper read before the Society of Arts, March 6th.

† Figures in parentheses relate to patent specification or date.

Digitized by Google

which rock on one another at a point of mutual contact which varies the "mechanical advantage" of the system, and partially or wholly, according to the curvature, compensates for the great increase of force as the distance of the armature diminishes.

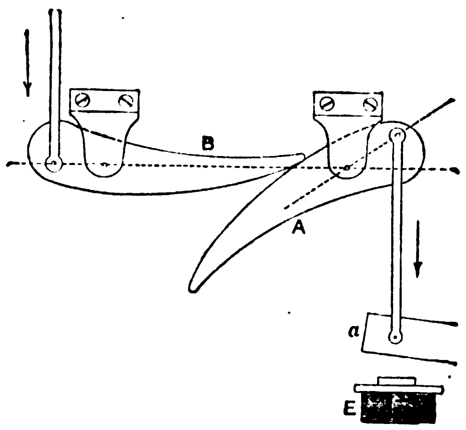

Fig. 1.—Houdin's Equaliser.

The form of the equaliser of Foucault, as used in the Foucault-Duboscq lamp, is depicted in Fig. 2. Here the armature, *a*, which is stiffly pivoted eccentrically to allow of adjustment, is attached to a lever, A, whose fulcrum is at F, and the opposing force of a spring, *s* (itself adjustable by the screw, *r*), is applied through the curved rocking lever, B. The vertical arm attached above F carries the detent, D. Equalisers depending on use of a rocking lever are to be found in several lamps. (Serrin's lamp; also Mackenzie, 95[82], and Common, 626[82]).

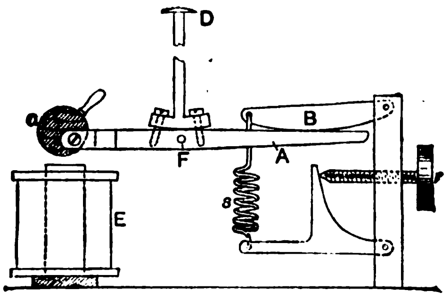

Fig. 2.—Foucault's Equaliser.

Returning from this digression, we have now to go separately over the eight items of the schedule, and point out how the various necessities have been met by the ingenuity of various inventors. As it is impossible to mention all instances of carrying out a principle, reference is made only to a few cases, preferably to the best known lamps.

(A.) Driving Power.

The following devices have been used:

1. *Gravity.*—Descent by its own weight of upper carbon-holder (innumerable lamps); ditto, aided by weights specially attached (Gulcher, 1915[82]); ditto, partially opposed by coiled spring to compensate for consumption (Siemen's, 365[83]); clockwork driven by weights (Staite, 11783[47]); lower carbon floated upward in mercury (Tommasi, 4405[79]).

2. *Coiled Spring.*—Drives by pinion and rack, or pulley and cord (Foucault, 1848, Staite, 11449[46]). Differential action of two coiled springs (Foucault-Duboscq lamp).

3. *Electromagnetic Motor.*—(*a*) Suction of core by solenoid; (*b*) electric motor rotates and drives carbon rod (Bousfield, 523[79]; Breguet, &c.); (*c*) electromagnetic vibrator drives carbon rod (Clark-Bowman, 1182[83]; Newton, 1623[83]; Pieper, 4133[83]; Holmes, 769[81].)

4 *Hot Air.*—Heated air rising from lamp drives fan to propel carbons (Varley, 5656[81].)

(B.) Striking Mechanism.

To strike the arc requires mechanical devices; but as these are to be actuated by the current itself, it is appropriate first to consider what electric mechanism is necessary or sufficient to actuate the movement. Assuming that the carbons are initially in contact when there is no current, the current when turned on must part them; the appropriate device is therefore an electromagnet (or solenoid with its core in lieu thereof) having its coils in the main circuit of the lamp. (Foucault, 1847; Staite, 11783[47], and in the vast majority of modern lamps.) If, however, the carbons are initially apart, the lamp must itself bring them together; and the appropriate device to actuate this movement will be an electromagnet (or solenoid) connected as a shunt, and therefore having fine wire coils of high resistance. Such an arrangement will bring the carbons together by the action of the by-pass current, and as this falls almost to zero on the contact of the carbons, they will be at once parted (and the arc struck) by the opposing force: this force may be that of gravity (Lontin, 1875) or a spring (Lever, 2092[83]; Thomson-Rice, Fig. 33). The disadvantage of this second method is that the initial resistance of the whole series of lamps standing with their carbons parted is enormous unless there is a cut-out circuit. Another method of striking the arc is by cutting out a main-circuit electromagnet (Crompton, 346[82]; Bright, 377[82]).

The modes of parting the carbons are various:

1. Drawing both carbons asunder by gearing (Foucault-Duboscq lamp).
2. Drawing down the lower carbon by electromagnet placed in base (Staite, 11783[47]; Serrin, Breguet, Sellon, Newton, Pieper, Holmes, &c.), or by electromagnet situated at top (Crompton "E," 1881; Gramme; Silvertown Co.; Fein, 1888).
3. Lifting upper carbon rod (Roberts, 14193[52]; Slater and Watson, 212[52]; and the vast majority of modern lamps, Brush, Siemens, Crompton, Pilsen, Brockie-Pell, Thomson-Houston, &c.), or lifting upper carbon by an electromagnet situated in the carbon rod (Abdank, 1884); or by lifting bodily the upper carbon and the whole of the feeding train (Crompton, 346[82]; Fyfe and Main, 3821[81]; Berjot, Wood, Hochhausen, Maxim, 1649[80]; Gümpel, 253[81], &c.); or by rocking the feeding train around a centre (Brockie, 2370[82]; De Puydt, Fig. 23).

The mechanical devices for performing these various actions are numerous, and their action is complicated by the endeavour of many

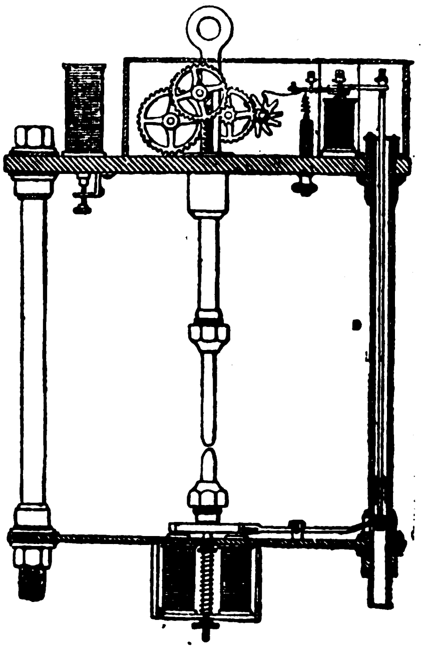

Fig. 3.—Breguet Lamp.

inventors to cause the same mechanism which initially strikes the arc also subserve the purpose of feeding the carbons. In some lamps, however, these functions are kept separate. An example of a lamp in which the striking and feeding mechanisms are kept separate is afforded by the Breguet lamp (Fig. 3), in which an electromagnet draws down the lower carbon-holder to strike the arc, whilst the feeding is accomplished in the subsequent gradual descent of the upper carbon. In the lamps of Newton, Sellon, and Holmes, there is used the special form of short-range electromagnet, *a* (2 in the list), having a central core and external tube of iron. There is a very numerous class of lamps in which a clutch is caused to grip the upper carbon-holder, and then to raise it so as to strike the arc; the same clutch being subsequently so operated as to permit the carbon-holder—a smooth rod—to slide down by degrees as required, to feed the carbon pencil forward. Such devices are best considered under the heading of feeding mechanisms.

The adjustments of the striking mechanism may be of two kinds: (1) adjustments of range, such as limiting stops and set screws; (2) adjustments of force, such as regulable spring shown in Fig. 1 at the bottom.

The main-circuit electromagnets, and solenoids, used for striking the arc, are wound with a wire of large enough section to carry the required current without undue heating, and are of small resistance. The weight of copper wire employed varies from one to four pounds; and the resistance varies from 0·05 to 0·2 ohms.

(C.) Feeding Mechanism.

The electric devices here differ in the case of lamps for parallel working and lamps for series working.

(*i.*) *For Lamps in Parallel.*—Assuming that the supply mains are kept at constant potential, then the lamp mechanism must be responsible for keeping the other factor of the electric power—namely, the current through the lamp—at a constant value. That is say, whenever by reason of the burning away of the carbon points the arc grows long, offering more resistance, and therefore reducing the current below its normal value, the lamp must automatically feed the pencils forward, and so readjust the current. It is obvious that, in this case, the weakening of the current through the lamp may be caused to bring the feeding mechanism into operation by the use of an electromagnet (or solenoid) in the main circuit. For if the armature of this electromagnet be held back by a spring or weight which only just counterbalances the pull of the magnet when the current is normal, the weakening the current will at once cause a movement of the armature which may be utilised to relax a clutch, lift a detent, or release an escapement. And it is also obvious that in this case it is possible to arrange the same electromagnet which strikes the arc to actuate the feed. Examples of the use of a single main-circuit electromagnet to actuate both the striking and the feeding mechanisms are to be found

Digitized by Google

in the Serrin lamp, in the Gulcher lamp, and in the Brush lamp as arranged for parallel working.

(*ii.*) *For Lamps in Series.*—Assuming that the dynamo is doing its duty, and keeping the current constant, then in this case the lamp mechanism must be responsible solely for keeping constant the potential between the terminals. Whenever by reason of the burning away of the carbons the arc lengthens and offers more resistance, if the same current is still supplied to it and forced through this greater resistance it will burn more brightly, and the difference of potentials between the terminals of the lamp will rise above its normal value The lamp must then automatically bring its carbons nearer, and readjust the potentials to the proper number of volts. It is obvious that the appropriate device to actuate the feeding mechanism must, in this case, be something that can play the part of a voltmeter; and will actuate the mechanism when the volts rise above their normal value. Practical voltmeters are of two kinds; (*i*) those which depend on the magnetic effects of the current that will flow through a wire of high resistance placed as a shunt across the two points between which the differences of potential exists, and (*ii*) those which depend on the heating effects of the current in such a wire. Either of these effects may be used to control the feeding mechanism of arc lamps; that is to say, the feed must be controlled by a shunt circuit, which will actuate the mechanism as soon as the potential rises above its normal value. The usual device is an electromagnet (or solenoid) of fine wire and of high resistance (from 200 to 400 ohms), the armature of which is counterbalanced by the force of a spring, or by gravity, or by an opposing main circuit electromagnet (or solenoid). An alternative device, not, however, in general use, is a long, thin platinum wire, which when heated by a current above the normal value will expand and actuate the feed. Thermal expansion has been attempted as a method of regulation by several inventors. (Lontin, 2074^{77}; Siemens, 2281^{78} and 2110^{79}; Munro, 1626^{82}; Edison, 2072^{82}; Pollak, 1888, &c.)

In the following table are comprised the several electrical arrangements for controlling the feeding mechanism:

(*i.*) *Constant Potential Lamps* (*for Parallel Working*).

(*a.*) Series electromagnet, same as used for striking. (Serrin; Gulcher; Brush; Crompton, &c.)

(*b.*) Series electromagnet, separate from the striking electromagnet. (Fontaine.)

(*c.*) Differential arrangement. Series winding partly opposed in shunt winding, on separate cores or parts of mechanism. (Lacassagne and Thiers, 2456^{56}; Siemens; Brockie-Pell.)

(*d.*) Ditto but wound on same cores.

(*ii.*) *Constant Current Lamps* (*for Series Working*).

(*a.*) Shunt electromagnet alone, acting against gravity or spring. (Lontin, 1877; Lever.)

(*b.*) Shunt electromagnet separate from the striking (series) electromagnet. (Numerous lamps. Breguet (Fig. 1); Crompton "E"; Sellon; Gramme; Pieper.)

(*c.*) Differential arrangement. Shunt winding pulling against series winding, on separate part of mechanism. (Lacassagne and Thiers; Siemens "differential"; Pilsen; Crompton-Crabb "DD"; Thomson-Houston; Brockie-Pell; Kennedy.)

(*d.*) Differential winding. (Numerous lamps. Brush; Weston; "Simplex.")

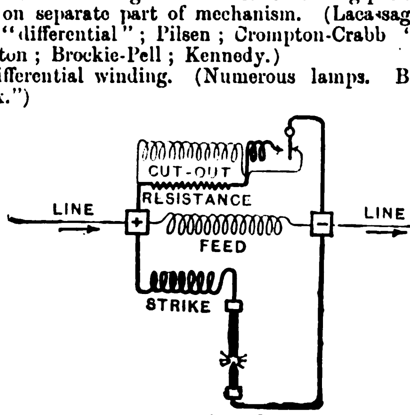

FIG. 4.

The typical arrangement of circuits for lamps that are to be run on a system of arc lighting in series, is shown in a generalised diagram in Fig. 4. The striking coil is in the main circuit; the feeding coil is a shunt, which if wound on the same core as the series-coil in any of the differential systems must be so wound that the currents circulate in opposing senses. There is also added a cut-out circuit, having both a shunt-coil and a small series-coil; but these must be so wound as to help one another's magnetic power, and the small series-coil must itself be a shunt to the main circuit of the lamp.

We are now prepared to enter upon the mechanical devices which have been suggested for the feeding mechanism of lamps. These are so varied, and run so curiously into one another, that no classification of them is entirely satisfactory. In a very large class of lamps there is a train of wheel work, usually driven by the weight of the descending carbon rods, the last member of the train being controlled through a detent or brake by the electromagnet that is responsible for the feeding of the lamp. Most, but not all, of these lamps have a rack upon the upper carbon rod to drive the train. But the rack lamps differ greatly amongst themselves. Again, there is another class of lamps in which the upper carbon rod is smooth, but is assisted and controlled in its descent by a clutch or clamp, the clutch or clamp being in turn controlled by the feeding electromagnet. But there are also rack lamps in which a clutch or clamp is applied, not to the rod itself, but to a wheel driven by the descending rack. There are, however, certain main features of classification about which there need be no ambiguity.

FEED MOTIONS.

(*i.*) *Rack and Train* controlled by—
(*a.*) Star wheel and detent (Staite, 18783^{47}; Foucault-Duboscq; Serrin, 653^{58}).
(*b.*) Fly and detent (Staite, 1848; Duboscq, 1855).
(*c.*) Brake-wheel and brake (Chapman, 739^{55}; Crompton, 346^{82}).
(*d.*) Escapement with pendulum or balance and detent (Siemens, 4949^{78}; Harding, 3166^{81}; Waterhouse, 5185^{81}).
(*e.*) Escapement and paddle (Waterhouse, 5185^{81}).
(*f.*) Governor with detent or moderator (Waterhouse, 5185^{81}).
(*g.*) Magnetic brake-wheel or detent (Brockie, 1713^{82}; Harling, 3473^{81}).
(*h.*) Liquid brake (Hopkinson, 153^{81}).

(*ii.*) *Clutch or Clamp on Rod*—
(*a.*) Tilting ring, tilting eyelet, &c. (Slater and Watson, 212^{52}; Brush, 2003^{78}; Lumley, 1249^{82}; Lever, 2092^{82}; Thomson-Houston; Waterhouse, &c.).
(*b.*) Split cone gripped by fork (Slater and Watson, 212^{52}).
(*c.*) Split nozzle forced into cone mouthpiece (Bürgin, 4820^{81}).
(*d.*) Split tube held together by oblique levers (Rogers, 3236^{82}).
(*e.*) Gripping springs at side (Lever, 3599^{81}; Munro, 1626^{82}).
(*f.*) Gripping fingers (Roberts, 14198^{52}; Joel, 5157^{79}; "devil's claws," Harding, 3166^{81}).
(*g.*) Washer jambed by ball bearing (Young, 1689^{82}; or roller, Newton, 4559^{81}).
(*h.*) Tilting clamp or nipping clamp (Common, 625^{82}).
(*j.*) Nipping lever (Grimstone, 1670^{81}; Mondos, 5490^{81}).
(*k.*) Scissors lever (Joel, 3970^{84}; Jarman, 563^{82}; Gerard-Lescuyer, 2992^{82}).
(*l.*) Spiral spring surrounding rod (Keilhotz, 1886; Thouvenot, 1887).
(*m.*) Forward-pointing springs (lobster trap) (Newton, 1623^{83}; Clark-Bowman, 1182^{83}; Holmes, 769^{86}; Hawkes, 157^{82}).

(*iii.*) *Clutch-wheel or Brake-wheel*—
(*a.*) Nipping lever outside brake-wheel (Gramme, 1861; Common and Joel, 1041^{81}; Brockie, 4419^{82}).
(*b.*) Nipping lever inside rim of wheel (Union Co., 392^{82}; Brockie, 4419^{82}).
(*c.*) Elastic band brake (Statter, 2985^{85}).
(*d.*) Elastic internal ring brake (Siemens, 6987^{87}; Fein, 1888).
(*e.*) Wheel lifted against brake or detent (Bürgin, 4820^{81}).
(*f.*) Brake-wheel lifted upon brake lever (Gümpel, 253^{81}; Crompton-Crabb, 2539^{83}).
(*g.*) Friction-pad on rim of wheel (Abdank, 1882).

(*iv.*) *Screw Motion.*
(*a.*) Screw worked by weight of upper rod (Hopkinson and Muirhead, 153^{81}; Cance, 3976^{81}; Akester, 2419^{82}).
(*b.*) Screw worked by motor (Tchikoleff, 1874).
(*c.*) Screw worked by step-feed (Street-Maquaire, 9666^{85}).
(*d.*) Screw worked by vibrated wheel (Siemens, 6987^{87}).

(*v.*) *Cord and Pulley Motions*—
(*a.*) Cord and pulley to core of solenoid (Archereau, 1848; Jaspar, 83^{79}).
(*b.*) Cord and pulley connecting carbons, with long-travel solenoid (Pilsen lamp, 1397^{80}; Doubrava, 1033^{84}).
(*c.*) Cord gripped by controlling cam (Harding, 4590^{79}).
(*d*). Cord and pulley for differential feed (Weston, 1883; Kennedy, 1888).

(*vi.*) *Step-by-Step Motions*—
(*a.*) Step detent worked by electromagnet (Deleuil, 1856; Brockie, 898^{82}; Gatehouse and Kempe, 2569^{82}; Kennedy, 5524^{81}).

(*vii*). *Magnetic Clamps and Clutches*—
(*a.*) Tilting magnet clutch on rod (Roberts, 14198^{52}; Gulcher, 2038^{81}).
(*b.*) Magnetic clamp on break-wheel (Harling and Hartmann, 3473^{81}; Hardt, 1886).

(*viii.*) *Electric Motor Action*—
(*a.*) Motor screws carbon up or down (Tchikoleff, 1874, and 2198^{81}; Maquaire, 1889).
(*b.*) Winds up with cord or rack (Andrews, 2321^{79}; André, 2764^{80}; Bousfield, 523^{79}; Breguet, 1879).
(*c.*) Motor itself controlled by shunt magnet (Thomson-Houston, 315^{80}).
(*d.*) Motor with copper damper (Thury, 1888).

(*ix.*) *Hydrostatic and Pneumatic Action*—
(*a.*) Carbons controlled by admission of liquid or gas (Lacassagne and Theirs, 2456^{56}; Hopkinson, 3509^{80}; Leibold, 1886; Sedlaczek, 1883).

(*x.*) *Vibrating Feeds*—
(*a.*) Make-and-break lever vibrate forward-pointing springs (Newton, 1623^{83}; Pieper, 4647^{85}; Holmes, 769^{86}).

(*b.*) Pendulum or governor, having rate varied by magnet (Waterhouse, 5185[81]).
(*c.*) Rack-train controlled by magnetic retardation on copper wheel (Niaudet, 1878).
(*viii.*) *Hammering Feeds*.—
(*a.*) Rod driven through clutch by vibrating hammer (Letang, 5509[87]; Capito and Hardt, 1887).
(*b.*) Ditto, by tilting lever (Jolin, 2570[83]).
(*c.*) Ditto, by magnetic pile-driver on rod (King, 1888).

Outside the classification adopted above are several well-marked features of mechanism; one of these is the *parallelogram motion*. A typical case of this is afforded by the well-known Serrin (653[59]) lamp (Fig. 5). A jointed parallelogram is constituted by the pieces which meet at A B C D. The side, A C, is fixed, being part of the frame, whilst the levers, A B C D, rise and fall through a small angle, carrying with them the upright, B D. To this upright is fastened a sleeve, through which the lower carbon-holder passes. This moving parallelogram is held up by a spring, *s*. When the electromagnet, E (in main circuit), attracts its armature, *a*, the parallelogram, and with it the lower carbon, sinks, and so the arc is struck. At the same instant a projecting triangular detent, U, engages against the star wheel of the driven train and locks it, so that the upper carbon cannot descend. As the carbons are consumed the current is weakened, owing to the increasing resistance of the lengthening arc, and the electromagnet lessens its attraction; consequently the parallelogram gradually rises, until a moment occurs when the detent ceases to lock the star wheel. The upper carbon-holder is now free to descend a little, driving the train of wheels, shortening the arc, restoring the normal current, and so again causing the electromagnet to pull down the parallelogram and lock the wheels. Parallelogram motions are to be found also in Bürgin's lamp (4820[81]), and in Siemens' pendulum lamp (4949[78]).

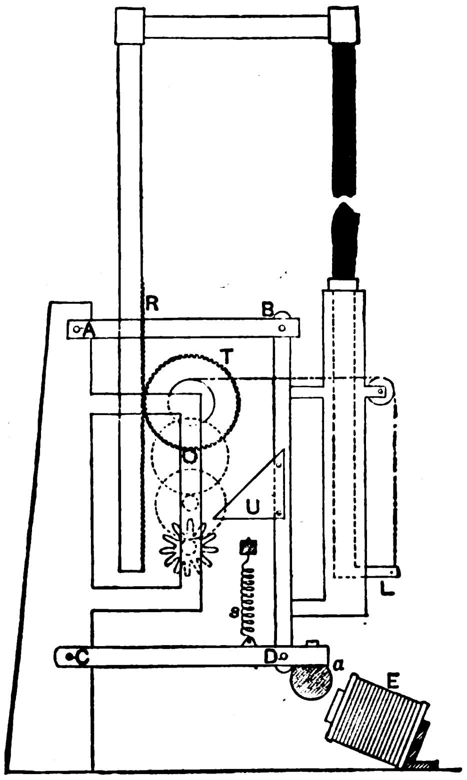

Fig. 5.—Serrin's Lamp.

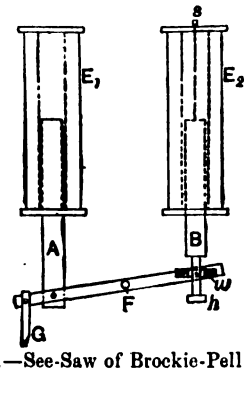

Fig. 6.—See-Saw of Brockie-Pell Lamp.

Another characteristic mechanism is the *see-saw* lever. Fig. 6 shows the form used in the Brockie-Pell lamp (12681[85]). The earliest use of the see-saw, attracted at opposite ends by series and shunt magnets respectively, occurs in the lamp of Lacassagne and Theirs (2456[56]); whilst modern examples are Weston's lamp, the Thomson-Houston lamp (Fig. 14), and Fein's lamp of 1883. (Also Moffat and Chichester, 3441[81]; and Chadburn, 2755[81], where the see-saw works a clutch). A compact modification of the see-saw mechanism occurs in one form of Weston's lamp, and again in Kennedy's lamp of 1888 (Fig. 10). Here the lever is replaced by a pulley over which passes a cord or ribbon of metal. In this lamp the shunt solenoid is furnished with a plunger core, whilst the series solenoid on the left has a plunger and an external iron mantle to increase its power. The smaller pulley communicates the motion to a clutch. The advantage of the see-saw, and of its pulley equivalent, is that such an arrangement enables the lamp to be used as either a constant potential lamp or as a constant current lamp. In the former case the shunt-coil holds up its end, whilst the see-saw is operated by the variations of the current in the series-coil. In the latter case the actions are the inverse of this.

The *rack-train* mechanism which forms the first class in the preceding list, presents two special points. As this mechanism is in itself non-retractile, and can only propel the carbons forward, it cannot be used with non-homogeneous carbons of second quality unless special provision is made in the striking mechanism of the lamp for a retractile movement. There is nothing retractile, for example, about the Breguet lamp (Fig. 3), but there is about the Serrin (Fig. 5), for the lower carbon-holder (which descends to strike the arc) is never held tight down by the electromagnet, but takes up a position of equilibrium. The other point is that in these rack-train lamps some device is requisite to lock the train at the instant of striking, otherwise the feed motion would neutralise the strike motion. In some lamps (Breguet, Sellon, &c.,) there is a mechanical connection from the striking part to lock the feed. In some other lamps the action is performed electrically. In the De Puydt lamp (Fig. 24), a pin on the train frame engages with a forked connecting-piece from the feeding-lever.

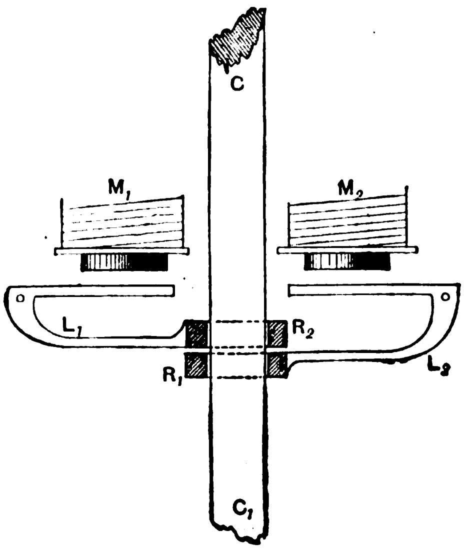

Fig. 7.—Slater and Watson's Clutch.

A characteristic arrangement, applicable to rack-train lamps, is that in which, for the purpose of striking the arc, the whole train mounted in its framework, together with the rack and the upper carbon rod, is bodily lifted by the use of an electromagnet in the main circuit. (Crompton, 346[82]; Fyfe and Main, Hochhausen, Gümpel, Berjot, Wood, Maxim, &c.) More neat is the method of rocking the train bodily around the axis of one of the wheels of the train. (Brockie, 2370[82]; and De Puydt, Fig. 23.)

Passing from the *rack-train* lamps to the *clutch* lamps, it may be noted how much ingenuity has been expended in attempting to find a form of clutch which will prove reliable under all conditions of working. Two of the very earliest forms of clutch mechanism are worth recalling in this connection. These are both due to Slater and Watson (212[52]). The first (Fig. 7) shows a carbon rod sliding through a couple of rings or eyelets, which are tilted by the attraction of an electromagnet to grip and raise the rod. In the second (Fig. 8) the clutch consists of a split conical washer, the two halves of which are hinged together. These are compressed by the rising of a fork, which nips and raises them. The tilting ring introduced by Brush is too well

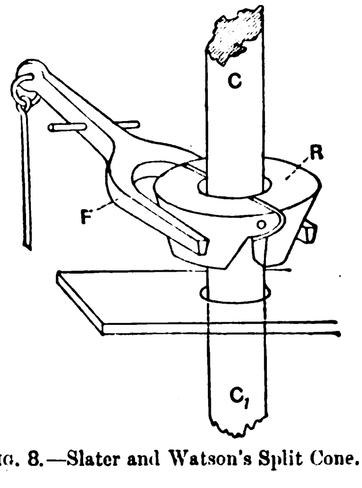

Fig. 8.—Slater and Watson's Split Cone.

Digitized by Google

known to need comment. Lever's modification of the tilting ring is shown in Fig. 9, the rim below the ring causing the thrust to act more obliquely at first, and allowing the clutch to work even when the aperture is considerably worn. In the latest forms of this clutch, the ring has a tail-piece which is hinged to the frame of the lamp.

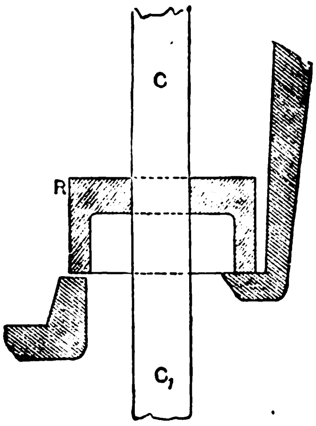

FIG. 9.—Lever's Clutch.

Another successful form of tilting clutch is shown in Fig. 10, which represents the mechanism of Kennedy's lamp. The clutch has a long tail, provided with an adjusting screw to regulate its position, and bears against the carbon rod by a slender spring, *s*, above. It is

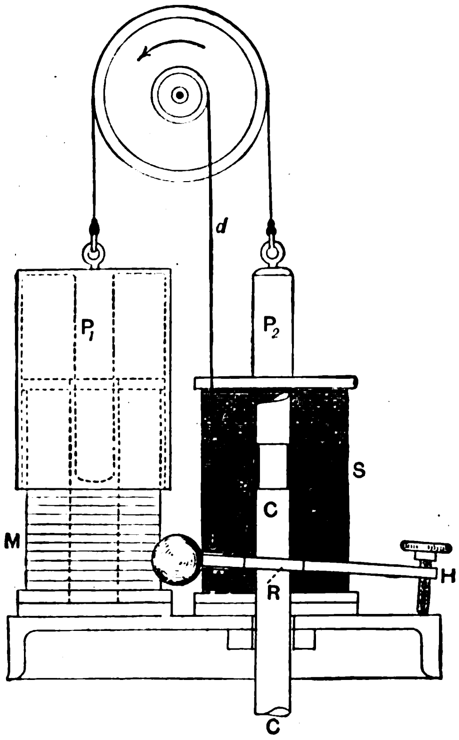

FIG. 10.—Kennedy's Lamp.

worked by a thin cord, *d*, running over a pulley in connection with the differential arrangement of shunt, S, and series, M, solenoids described above. A clutch provided with a spring that bears against the carbon rod is also found in the Clark-Bowman lamp (1182^{83}), the

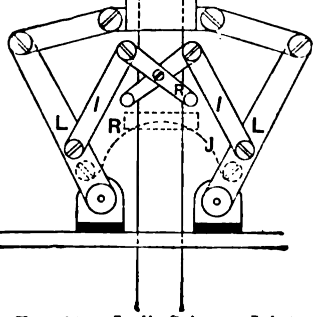

FIG. 11.—Joel's Scissors Joint.

feeding in this case being accomplished whilst the clutch is held up, by giving to it a mechanical vibration. In the Kennedy lamp the spring on the clutch also serves the purpose of finally arresting the descent of the carbon-holder, catching on a groove cut around its upper end when the carbon pencil is all consumed. Another simple clutch with spring mounting, worked by the mutual repulsion between two similarly magnetised cores, has been devised by Swinburne (11893^{84}). Clutches of the knee-lever type have been devised by Lorrain (183^{83}) and Joel (3970^{81}). The more complex "scissors-joint" levers, used in one of Joel's lamps, are drawn in Fig. 11. Their action is obvious, as their upper end is raised by the upward pull of the electromagnet or solenoid they grip, and raise the carbon rod, and

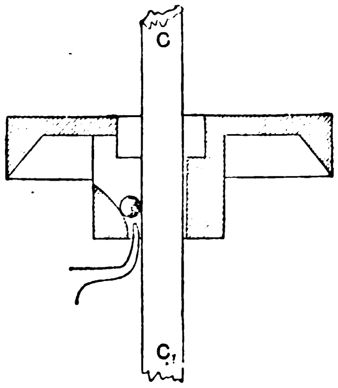

FIG. 12.—Newton's Roller Clutch.

they relax their grip on being lowered to feed the arc. Very similar devices are found in Gerard's and Jarman's lamps. An ingenious

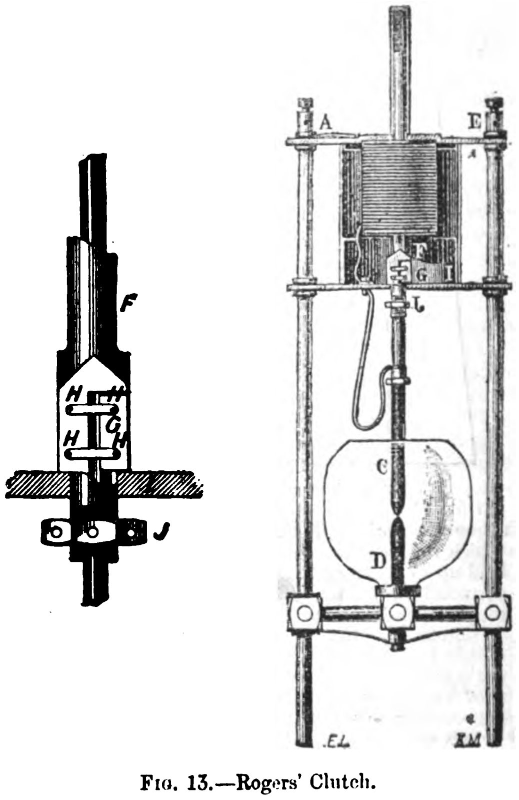

FIG. 13.—Rogers' Clutch.

species of clutch, by F. M. Newton (4559^{81}), is illustrated in Fig. 12. This consists of a ball bearing or roller bearing, which on the raising of the collar in which it lies jams against the carbon rod and raises it. Another extremely simple clutch (Lorrain, 639^{82}) consists of a plunger working horizontally through a solenoid, pressed sideways by a spiral spring against the carbon rod; the pressure of this is taken off, when feeding is required, by the pull due to the current in the solenoid, which is connected as a shunt. Rogers' (3236^{82}) simple and very efficient form of clutch consists of a split tube, the parts of which are connected together by a pair of oblique links, making a sort of parallel motion. This form is shown in Fig. 13.

which I have yet seen. But it has been very costly to establish. Many of the details contain hints of the greatest use to those who are at work on this subject. The whole plant has been contracted for by Messrs. Ganz, of Buda-Pesth.

There are two self-exciting alternators of 150 h.p. each and two independently excited ones of 600 h.p. each. These give 42 amperes and 160 amperes respectively, and 2,000 volts. At present 9,000 glow lamps of 16 c.p. are supplied, and over 200 arc lamps. All the machines are capable of working in parallel, even the large and small ones together. The number of alternations is 5,000 per minute, or 2,500 complete periods. The greatest distance to which current is at present supplied is 4½ kilometres, or about three miles. The feeders all go to the Piazza Venezia, and then branch off into three mains in different directions. The loss in the secondary circuits due to loss in the feeders at present is only 0·6 volt at the maximum, and that due to the mains is the same, the length of feeders being 1,600 metres.

Siemens' concentric conductors are used throughout. The feeders are each 220 square millimetres section, or 0·35in. Drawings of the junction boxes by Siemens and Halske are shown, indicating the means of attachment by clamps of the two ends of the inner and outer concentric cores. The cables are laid in a wooden box, which is then filled with cement. Seventeen kilometres of cables have been laid up to January, 1889. The feeders have been working since September, 1887. The transformers are all of 10 h.p., with about 4 amperes in the primary and 75 in the secondary. One hundred and ten volts are used in the secondary; but the secondary coil has three terminals—one half-way along the length of wire. This is to enable a three-wire system to be used for the secondaries when arc lamps are used, consuming, with their resistances, 55 volts each.

The old type of converter, with iron wire wound round the copper coils has been abolished. The iron part is built up of circular flat ring-shaped discs of iron. These are firmly clamped together by iron clamps, which form the support of the instrument. The copper coils are wound upon the segments of the rings between the clamps. The primary coil is underneath the secondary. The converter has an iron circular disc at top and bottom fixed to the clamps, and this enables the instrument to be easily rolled about without injury, which facilitates handling. On the top is a porcelain disc, on which are placed the terminals and fusible cut-outs. These are short strips of thin metal held in pasteboard, and can be slipped in and out with the greatest ease.

The small machines are intended to work 1,000 lamps of 60 watts. There are 20 poles, and 250 revolutions per minute. A derivation is taken from a commutator to excite the machine. Sulze engines are used for these dynamos, acting direct on the dynamos. The steam pressure is 120lb.

The automatic resistance for regulating the exciting current, invented by M. Blathy, is very effective. The exciting current passes through a solenoid actuating an iron rod which is supported at one end of a balanced lever. The bar is weighted with a float in water, and water can be put into the float. On the top of the iron bar is a cup of mercury which, in falling, breaks contact with the ends of wires dipping down into the mercury cup. These ends are at different depths, so that the wires are cut out of circuit in succession. The wires go to resistances. This automatic adjustment acts well over a considerable range.

The exciters for the large dynamos are driven by Westinghouse engines. They are governed by hand for the large changes, and then the automatic regulation comes in. Such a method of regulation is necessary with machines having so large an amount of self-induction. This is the only satisfactory regulation of the kind which I have seen at work. It is one of the small details on which the success of a station depends, but which are often forgotten by the inexperienced until the want is

The two large machines have 40 poles each on the revolving field-magnets. Both field-magnets and armature are divided into two series in parallel. When the machine is illuminated by an arc light, to which it supplies the current, a curious optical effect is produced. The arc being periodically made and broken, the revolving magnet-poles are seen fixed in position, and the amount of lag with different loads can be seen directly. The efficiency of these machines is said to be 90 per cent., including the exciting current. These machines are so constructed that the cover which contains the armature-coils can be drawn away, by means of a handle, shown in the photographs exhibited, over the electromagnet ring, without the necessity of using any hoisting tackle or other machinery. Moreover, the construction of the fixed armature is such that any single coil can be removed in a few minutes or exchanged. The iron of a section of the armature is in this case removed with the coil. The iron plates of which these armature sections are made are T-shaped, so that the centre of the coil is filled with iron. In the smaller machines there is not nearly so much iron in the coils. In the 600 h.p. machines the energy absorbed in exciting at full load is said to be 3½ per cent. of the full load.

The T-shaped iron plates of the armature are pressed together by strong bronze press-plates and a screw. The wire bobbin is then slid on and held by screws. These segments are fastened to two traversers by the screws, which traversers are in turn screwed with an insulating layer to the side-plates of the framework of the machine.

The field-magnet wheel is constructed as follows: U-shaped soft iron sheets are so arranged together as to form a star, to which is added a similar star, with an insulating layer between, placed in such a way that the interstices between the sheets composing the lower star are covered by the sheets of the upper star. In this way many iron laminæ are put one upon the other until there are sufficient to form the whole electromagnet wheel. The pile so formed is then pressed together to form a compact whole by means of two stiff discs, two bosses, and the screws. The bobbins are slipped on to the core, and held down by means of the bobbin-holder and screws. The subdivision of the iron in the field-magnets is necessitated by the teeth of iron in the armature projecting inwards through the coils.

The large engines are by Ganz and Co. They are carefully balanced, and are provided with starting gear. A drawing was exhibited of the switchboard, which is very ingenious but very expensive. The board is about 8ft. high and 17ft. long. It is divided into four sections, one for each dynamo, and each section is divided into six, one for each pair of feeders. A pair of 4ft. horizontal bars runs along each dynamo section, connected with the two poles of the dynamo. Two vertical bars descend from these at each of the six parts allotted to the six circuits. Six pairs of horizontal bars are connected to the six pairs of feeders (only three are as yet in use), these pairs being one over the other. At each feeder section a pair of vertical copper bars descend from the horizontal feeder bars corresponding to that section. Thus we have at each feeder section two vertical dynamo bars and two vertical feeder bars, the lower ends all being at the same level. Mercury cups can be raised to connect each dynamo bar with a feeder bar, or lowered to disconnect them. The chief object of the switchboard is to enable us to switch any number of dynamos in or out of connection with any feeders simultaneously and instantaneously. I will now describe this action, referring to the diagram. In the normal condition of the crank and handle would be as shown in the side elevation, one crank to each mercury cup. If it be required to put on to the dynamo the feeder No. 6, and take off No. 1 from the dynamo, represented by this part of the switchboard, the handles, with cranks, corresponding to these feeders are pushed bodily to the left. The web of each crank is thus made to fit in a vertical slot in the disc, which disc is connected to the bevel wheel by a hollow spindle to which the bevel wheel is keyed, this bevel wheel gearing with the bevel wheel keyed on to the shaft, running the whole length of the switchboard. The crank of No. 6 would be diametrically opposite that at No. 1, since one was disconnected and the other connected to a circuit. The lever is then thrown over against the other stop, causing the crank No. 6 to be raised from its lowest to its highest position, and that of No. 1 to be correspondingly lowered.

The voltmeters in this station by which the pressure at the lamps is kept constant are regulated by means of two circuits, one being a shunt on the dynamo terminals, and the other carrying the main current. These are passed through converters, and the secondary currents actuate a solenoid in opposite directions. This compound-wound voltmeter indicates the pressure at the lamps, and is maintained constant. Prof. Mengarini has devised an ingenious recording voltmeter for marking in a daily curve the pressure at the dynamo terminals at each minute of time. These show variations of 5 volts at different hours.

There are 50 converters now at work, each of 10 h.p. The efficiency of these converters is 95 per cent. at full load. That of Messrs. Ganz's 5 h.p. converters is 92 per cent., and the 2½ h.p. is 88 per cent. This is far higher than with many of those now made in England. The House of Parliament is lighted by four banks of five converters each.

PART II.

Lessons to be Learned from Foreign Central Station Lighting.

I propose now to deal with some of the problems of central station lighting which we in London have now to face.

I judge by the practices I see common in this country that I shall, as to my opinions on many points, be at variance with some of my brother engineers, because in the work which has hitherto been done I see that the experience of foreign countries has very often been neglected, and the rule seems to be to neglect the opportunity of utilising the experience gained at great expense of time and money in foreign countries, while our progress was being retarded by the Electric Lighting Act. But my conclusions have been arrived at after a most careful consideration of the successful work which has been done in Europe and America, and I am ready to condemn foreign practice when

Digitized by Google

necessary. All I say is, that we ought to benefit by the experience abroad, and I know that those who have the best interests of electric lighting in England at heart agree with me.

This neglect of the principles laid down in other countries I find to exist whether the central station be used for continuous or alternating currents. I foresee great danger in store for us if we do not discuss the difficulties fully at the outset, and I trust that the discussion that this part of my paper will give rise to will assist to make the progress now being made in England a thorough success.

Three-Wire System.

My first remarks will be about the direct system of supply at low pressure—a system which may be much more frequently employed with advantage than many people seem to imagine. It is not suited for a large district, but it has some advantages. 1. That the steadiness of the light can be increased, the fear of accidents diminished, and the amount of machinery reduced, by the employment of storage batteries. 2. If batteries are not used, the loss of energy in transformation is avoided.

Let us deal first with the case where all the dynamos are working in parallel at the same pressure. This is the Edison plan, and is very generally adopted. I have shown in my Cantor Lectures* that when we extend beyond a certain distance from the central station on the system at present used, the question of economy, as established by Sir William Thomson's law for the size of conductors, must be partially abandoned, and a different size used, in order to prevent the variation of electrical pressure over the area being too considerable under the varying loads. With the "two-wire" system the law of economy holds only up to a very short distance; with the "three-wire" the distance is doubled. This is due to the fact that the pressure is doubled, and this is the principal advantage possessed by the three-wire system. In Berlin and Milan the two-wire system has hitherto been adopted, and the enormous amount of capital expended in copper is a proof of the costliness of the system. I hold that in no case of central station work at low pressure ought the two-wire system to be adopted. In this I am supported by the universal practice in America, where the two-wire system for low-pressure distribution is now totally abandoned. I am also supported in this by the practice in Berlin, where all future work is to be done on the three-wire system. In spite of these considerations, I am not aware of a single case where it is in actual use in England since the experiments at Leamington have been abandoned. The two-wire system is used at a good many places in this country. The result of experience probably is that the three-wire system can be profitably worked to a maximum limit of half a mile where the price of gas is over 5s. per 1,000 cubic feet. Beyond that distance the profits diminish too much. In London I do not think it could be well done beyond 400 yards, as a general rule.

Feeders.

I now come to another principle of distribution, which is strangely, and, I believe, almost universally, neglected in this country. I refer to the use of "feeders." Let me distinguish between the use of feeders and mains. Mains are conductors from all parts of which branches may be laid into the houses. Feeders are conductors leading from the central station to various points in the system of mains, and which are not tapped on the road. In Berlin and Milan the practice, first started in America, is followed of laying down a network of mains and supplying current at numerous points in them by means of feeders. This serves to equalise the pressure over the entire districts under varying loads. In England this practice is not generally adopted. The result is that if you wander over a district supplied by electric light in England, you find that when the supply of current is small the lamps are equally bright over the whole town; but when there is a large demand for light, the glow lamps near the station are far too bright, and those at a distance are far too dull. In Berlin, where half the capital spent in conductors has been used for feeders, the lamps are, all over the district, equally bright at all times. Not the slightest difference can be perceived at different hours of the day or night. I hold the opinion that a station with low-tension current without feeders is badly engineered.

Using Dynamos at Different Pressures.

It is the universal practice abroad to make the size of the feeders such that the loss of pressure in these feeders is the same in all. This involves the use of very large feeders when their length is great, and great waste of energy when the length of feeder is small, but it enables all the feeders to be supplied by dynamos at the same pressure, which may therefore work in parallel. This arrangement is simple to work, but it is wasteful. I find that we can save enormously in copper at a slight extra trouble in working the central station. I would prefer to see the feeders divided into two or three groups, feeders in each group having the same length, and having the same loss of pressure.

* Cantor Lectures, "On the Distribution of Electricity," Society of Arts *Journal*, 1885.

All these feeders would be made of the economical section, according to Sir William Thomson's law. When the station is at full load, the dynamos working long feeders have a higher pressure than those working short feeders. When the load is light all the dynamos would work at the same pressure, because the loss in the feeders is insignificant. At such times all the dynamos might be joined in parallel, or the feeders might all be upon one dynamo.

Position of Pilot Wires.

In nearly all cases of low-pressure distribution the pressure is regulated by a "pilot wire" coming from the point where the feeder meets the main. These pilot wires indicate the pressure at those points upon a voltmeter at the station, which is kept at constant reading by an attendant. Sometimes all the different pilot wires are grouped together at the station and indicate the average pressure on the voltmeter. This is done at Berlin. At Milan, however, the pressure is varied according to a tabular rule when the current varies. The use of pilot wires is, however, very desirable, but I hold that hitherto the pilot wires have generally been placed in the wrong position. Suppose that a 4 per cent. variation exists over the district of mains supplied by any one feeder, and that the point where the feeder strikes the mains is kept at constant pressure, then the most distant lamp supplied by that feeder has a variation of 4 per cent. If, however, the pilot wire came from a point half-way between the most distant lamp and the feeder, and this point were kept at constant pressure, the maximum variation of pressure would be reduced to one-half, and would be only 2 per cent. It appears, then, that by properly placing the pilot wires the variations in pressure can be reduced to one-half; or, keeping the variations of pressure the same, the quantity of copper in the mains may be reduced to one-half.

In these suggestions as to dynamos at different pressures and as to the position of pilot wires I am supporting a course which has not been generally adopted anywhere, but the improvement ought only to be mentioned to receive general recognition.

Lamps of Different Voltage.

It has often been proposed to supply different parts of a district with lamps of a different voltage. In the ordinary plan of using feeders and pilot wires, the maximum pressure at the most distant lamp supplied by any feeder is the same as the pressure in the mains at the feeder. The minimum pressure may be, let us say, 4 volts less. Suppose 100-volt lamps are used, those near the feeder will always have 100 volts, but the most distant ones will have pressures varying from 96 to 100 volts. Ninety-six volts would make the lamps very dull; and if at the distant points lamps of 98 volts were used, the pressure would never vary more than 2 per cent. from the normal, and a better light would be obtained. This would be a very good arrangement if we could lay out a district from the beginning with all the positions of the lamps established, but it is found that as the station progresses a house which would have required 100 volts yesterday may require a limit of only 99 volts to-day, owing to the introduction of additional lamps between it and the feeder. Experiments which have been made in America on this plan have led to disastrous results and hopeless confusion in completing the scheme. This plan has been completely abandoned, and in the present state of the industry I think that this abandonment has been wise.

I do not think a greater variation of pressure than 2 per cent. up and down should ever be allowed if you wish to supply a satisfactory light.

I consider that success or failure of many electric light companies now doing central station work is very much dependent on their following or neglecting the proper rules for distribution, and I will illustrate the importance of these rules by a few examples.

1. A plain network by the two-wire system, fed at the central station with the economical size of copper conductors according to Sir William Thomson's law, say, of 1,000 amperes per square inch, and going to a distance of 480 yards, would have a difference of pressure to which the distant lamps would be subjected of 24 volts.

2. On the three-wire system this would be 12 volts with one-fourth extra copper.

3. With the same amount of copper as in the last, properly arranged with feeders, the feeding points being 160 yards apart, the maximum variation of pressure in any lamp over the district is two volts, if the pilot wires come from the feeding centres.

4. Everything remaining the same as this last, except that the pilot wires are placed in the proper position instead of at the feeding points, the maximum variation is only one volt.

Putting it in other words, the quantity of copper required to limit the variation of pressure over the district to a certain figure is in the last case one-twelfth part of what it is in the second case, and one-nineteenth part of what it is in the first case.

Digitized by Google

High-Pressure Distribution.

Before I leave the question of distribution, let me now apply the same rules to the "Gaulard and Gibbs" system of using alternating currents with high pressure in the mains and low pressure in the houses, the reduction in pressure being effected by means of an induction apparatus called a "converter." At the present moment these converters are usually put in parallel upon the mains. There is a general impression in this country that it is not necessary to have feeders supplying the mains, even though the distance extends to several miles. Here again the experience of other countries has been set at defiance, although in a large town like London the importance of this rule is greater than in most American cities, or in Rome. If such views continue to be adopted, the result will be as disastrous in the future as it has been in the past. In the most extensive system in this country, when there is a large demand for current, the distant lamps look like red-hot hairpins, even though the near lamps be at full brightness. This is due to defective distribution.

As already stated, there is a general belief in this country that to whatever extent the Gaulard and Gibbs system is used no trouble comes from variations of electric pressure over the district, even when the converters are placed in parallel. Let us look at this question a little closer. Returning to the two-wire system for low pressure, if we use 1,000 amperes to the square inch as the economical section for our conductors, the fall in pressure is 5 volts for 100 yards; the loss of pressure due to the house wiring amounts very generally to 2 volts; hence the total variation between the periods of maximum and minimum output is 7 volts per 100 yards, or about double what is permissible (4 volts); hence, with the two-wire system such a size of conductor at 100 volts pressure could only be used for a distance of from 40 to 50 yards. Let us see how this distance is extended by using a pressure of 2,000 volts in the mains and 100 volts in the secondary. With the same density of current the loss of pressure in the house will be now 5 volts for 2,000 yards, to which must be added 2 volts for the house wiring and $1\frac{1}{2}$ volts for loss in the converter, making $8\frac{1}{2}$ volts loss of pressure in 2,000 yards.

If we allow 4 volts variation in the lamps, which is quite a maximum, this allows only $\frac{1}{2}$ per cent. variation in the mains, and then the greatest distance to which conductors can extend is 200 yards. The only means of extending the district is by the use of feeders. In America the practice prevails of allowing only $\frac{1}{2}$ per cent. loss of pressure in the mains. I have taken a concrete case of 1,000 amperes per square inch, which may not always apply to actual conditions, but it shows the necessity of adopting the universal foreign practice of employing feeders even with high-pressure mains.

Pressure Indicators on High-Tension Circuits.

It would be highly inconvenient to use pilot wires with the Gaulard and Gibbs system, such as are used on low-tension circuits; for this reason compound-wound voltmeters are used, which indicate the pressure at the far end of the feeder. I have described those in use at Rome and Milan; I have also described elsewhere those used by Westinghouse in America. The principle of these indicators is to have one winding connected like an ordinary voltmeter with the terminals of the dynamo, and another winding in reverse direction to carry the main current. The diminution in the indication owing to this second winding is always equal to the fall of pressure in the feeders. Different inventors have applied different classes of apparatus for accomplishing this result, but it is needless to say that the working out of such instruments takes a long time, more especially in such an instrument as that employed by the Westinghouse Company, which is made interchangeable for all circuits by the insertion of six different plugs, representing six different losses in the feeders, converters, and house wiring, varying from 3 per cent. to 10 per cent., besides four plugs for the different maximum currents in use with any feeder. I draw attention to this point because I consider that the successful working of such a central station depends largely upon the use of such an indicator of pressure; and I find manufacturers in this country who have had little or no experience in central station work prepared to equip central stations with all the necessary measuring instruments, and I wish to feel confident that these manufacturers have realised the importance of such instruments; and I wish earnestly to impress upon them, solely in their own interests, the necessity of working out such instruments if they wish to redeem electric lighting in the metropolis from the condition into which some of the so-called pioneers of this industry have reduced it.

Insulation.

We have now to consider a very important, and perhaps the most difficult, part of the problem of central station lighting—How are we to preserve our insulation? It must be noticed that we do not require a high insulation for the sake of getting a small loss of current, but only because with many insulators the high insulation is more permanent, and permanency is the quality of insulation which is most to be desired.

(*To be continued.*)

ELECTRO-HARMONIC SOCIETY.

The next smoking concert of the Electro-Harmonic Society will be an amateur night, and will be held on Friday, March 29, 1889, at the St. James's Hall Restaurant (Banquet Room), at eight o'clock. The following is a list of artistes: Messrs. M. G. Walters, T. H. Harrison, G. Glass, James Swinburne, M. Holroyd Smith, W. M. Foxcroft, A. H. Moore, J. E. Kingsbury, Aug. Dotzheimer, J. Perry, Ernest Renton, and the Brothers Greenop; accompanist, Mr. Alfred Izard; musical directors, Messrs. T. E. Gatehouse and Arthur Thompson. A Broadwood piano will be used. The following is the programme:

PART I.

Piano Solo ...."Gavotte."..........................Handel.
Mr. Alfred Izard.
Song ...."A tar of the Queen's."................M. Watson.
Mr. M. G. Walters.
Violin Solo ....“Andante tranquillo.”............Ch. de Beriot.
(From Seventh Concerto.)
Mr. Aug. Dotzheimer.
Song ...."The devout lover."........ Maude V. White.
Mr. T. H. Harrison.
Piano Solo ...."Romanze in F sharp."................Schumann.
Mr. James Swinburne.
Irish Song ...."Selected."...........................
Mr. G. Glass.
Recitation......"The heart of the Bruce," or Edinburgh after Flodden. Aytoun.
Mr. M. Holroyd Smith.
Five Experiments in Thought Reading ....
Messrs. Ernest Renton and G. Glass.

PART II.

Æolian Zitters.....................Selection............................
Messrs. Greenop Bros.
Song ...."At bay."..........................M. Watson.
Mr. T. H. Harrison.
Piano Solo ...."La Crepuscule."............ Wollenhaupt.
Mr. A. H. Moore.
Song..........................."The King's own."..........Th. Bonheur.
Mr. M. G. Walters.
Cornet Solo........................"Sérénade."........................ Gounod.
Mr. J. E. Kingsbury.
Recitation { (a) The slave's first hour of freedom. . Anon. (b) Selection from "His first champagne." } Lemon Reade.
Mr. W. M. Foxcroft.
Piccolo Solo......................"Selected."........................
Mr. J. Perry.
Banjo Selection..................."Selected."........................
Messrs. Glass and the Brothers Greenop.

COMPANIES' MEETINGS.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.

An extraordinary general meeting of this Company was held on Tuesday last at Winchester House, Old Broad-street, Viscount Monck in the chair, for the purpose of ratifying an agreement between the Company and the Western and Brazilian Telegraph Company, Limited, "with respect to the working of the lines of the two companies and the division of the traffic receipts thereof."

The **Chairman**, in proposing a resolution in accordance with the object of the meeting, observed that directors were constantly asked at such meetings as that to state minutely the way in which transactions respecting the company were carried on. Although there might be nothing whatever to conceal on its own account, yet he asked them, as business men, whether any private individual would carry on his transactions under such conditions. No one cared to admit that he was losing by his business, and on the other hand, if great gains were shown, it might have the effect, especially in such a business as theirs, of attracting competition, which would very likely interfere with their future profits. They could not communicate the nature of their transactions to the shareholders without taking the public into their confidence, and, that might be injurious to the Company's interests, although they might not have anything to say which was in itself at all disagreeable. The only way he saw out of the difficulty was to ask the shareholders to extend their confidence to the Directors, who had conducted their affairs for about sixteen years in a manner which, he ventured to say, had not been, on the whole, unsuccessful. The Western and Brazilian Company was started at the same time as their own Company; but while they themselves would in about four years hence lose their monopoly rights to the traffic to Brazil, the monopoly rights of the Western Company would last for 40 years longer. Of course, the termination of the concession would not prevent the Company from working to Brazil, but they would lose the monopoly. Hitherto the two companies had worked in intimate relationship, taking a certain proportion of each other's receipts, but it was now wanted to make the connection permanent and more intimate. Under the proposed agreement their future relations would be regulated by the receipts being paid into a joint purse, from which each company would take a certain proportion—namely, 54 in the case of the Brazilian Submarine Company, and 46 in the case of the Western Company. The agreement contained an article, to which he attached great importance, enabling them to allow the Brazilian Government to come into the arrangement, if they should wish to do so, on terms to be agreed upon.

Digitized by Google

If that could be carried into effect, both companies would be placed in a very advantageous position, but the Brazilian Government had not as yet shown much wish to give its adhesion to the article. He hoped that the Government would in the future be better advised, and meantime the agreement would place the two companies on a very satisfactory basis for the future conduct of their trade.

Mr. Burt (the solicitor) then read the agreement, which is to take effect from the 1st inst., and under which the Western and Brazilian Company are to lay cables from Pernambuco to Bahia, from Bahia to Rio de Janeiro, and between Rio Grande do Sul and Montevideo.

Sir James Anderson seconded the resolution, which was agreed to.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.

An extraordinary general meeting of the Western and Brazilian Telegraph Company, Limited, was held on Tuesday last at Winchester House.

Mr. W. T. Andrews presided, and submitted a resolution for ratifying a working agreement between the Company and the Brazilian Submarine Telegraph Company, Limited.

Mr. Guesdon thought it unfair to call upon shareholders, at a few minutes' notice, to ratify an agreement on which Directors and solicitors had been engaged for several months. He suggested that the agreement should be printed.

The **Chairman**, in reply to questions, stated that the way in which the capital would be raised for the new cables which had to be laid by the terms of the agreement would be matter for another meeting. It was a well-known fact that certain telegraph concessions had been granted to other companies by the Brazilian Government, but most of those concessions were dead, and those that were not dead were dying. He could say nothing as to future concessions that might be made by the Brazilian Government; but the agreement before the meeting would consolidate matters so far as the lines of the two companies were concerned, and have a great influence in staving off competition.

The resolution was approved.

MONTEVIDEO TELEPHONE COMPANY, LIMITED.

At an extraordinary general meeting of this Company, held on Friday at the offices, Mr. Arthur Holland in the chair, the resolutions passed at the meeting held on the 27th of February as to the increase of the capital were duly confirmed, the increase being for the purpose of acquiring the business of the Gower-Bell Telephone Company, and thus consolidating the telephone business in Montevideo. At the conclusion of the meeting, the Chairman announced that an interim dividend at the rate of 6 per cent. to the 31st of December, 1888, would be paid on the preference shares on and after the 23rd inst.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts of this Company for the week ended March 15 amounted to £5,148.

West India and Panama Telegraph Company.—The traffic receipts of this Company for the half-month ended March 15 show an increase of £343 as compared with the corresponding period.

Western and Brazilian Telegraph Company.—The traffic receipts of this Company for the past week, after deducting the fifth of the gross earnings payable to the London Platino-Brazilian Company, were £4,074.

Eastern Telegraph Company, Limited.—This Company announce the payment on April 15 of a dividend of 3s. per share on the preference, less income-tax, for the quarter ending March 31, and an interim dividend of 2s. 6d. per share on the ordinary shares, tax free, in respect of profits for the quarter ended December 31.

Western Counties and South Wales Telephone Company, Limited.—The report for the year ending December 31 states that the capital expenditure was £27,885, making a total of £113,176 to date. The gross revenue was £32,206, against £23,597 for 1887. The amount of income carried forward to next year's revenue, as representing sums received in advance for periods extending beyond December 31, 1888, is £10,403, against £8,043. The working expenses were £8,337, against £6,693. After providing for the dividend of 6 per cent. on the paid-up preference share capital, the Directors recommend a dividend of half per cent. per annum on the ordinary shares, and that £200 be placed to the special reserve fund, carrying forward £1,246.

PROVISIONAL PATENTS, 1889.

MARCH 11.

4208. **The automatic regulation of E.M.F. or current in dynamo machines.** Herbert Tom Harris and Albert Gay, 27, Martin's-lane, Cannon-street, London.

4250. **Improvements in apparatus for attaching and suspending electric lamps.** James Ernest Spagnoletti and Joseph Crookes, 21, Cockspur-street, London.

MARCH 12.

4287. **Improvement in instruments for measuring electric currents.** John William King, 13, St. John's-square, Clerkenwell, London.

4296. **Improvement in galvanic batteries.** James Kynoch, 7, Bank-buildings, Church-street, Camberwell, London.

4336. **Improvements in electrical switches.** Thomas Spencer, 18, Warwick-street, Regent-street, Middlesex. (Harry T. Paiste, United States.) (Complete specification.)

MARCH 13.

4371. **Improvements in electricity meters, parts of such improvements being applicable to electrical clocks and other electrical instruments.** George Hookham, 7 and 8, New Bartholomew-street, Birmingham.

4407. **Improved method of and means for code signalling with electric telegraphs.** Henry Edward Montagu Dorrington Clotworthy Upton, 28, Southampton-buildings, Chancery-lane, London.

MARCH 14.

4448. **Improvements in or pertaining to incandescent electric lamps.** Francis Edward Elmore, Armaside, Cockermouth.

4484. **Improvements in electric distribution.** William Morris Mordey, 46, Lincoln's-inn-fields, London.

MARCH 15.

4519. **Improvements in electric cranes and hoists.** Wilson Hartnell, Benson's-buildings, Park-row, Leeds.

4530. **Improvements in coin-freed apparatus for obtaining a current of electricity during definite periods of time for producing electric light, and for other purposes.** Henry Sherley Price and Herbert John Dowsing, 115, Cannon-street, London.

4559. **Improvements in voltaic batteries.** Desmond Gerald Fitzgerald, 47, Lincoln's-inn-fields, London.

4566. **An improved method of distributing electricity for lighting purposes.** William Llewellyn Preece and Josiah Sayers, 24, Glycena-road, Lavender Hill.

MARCH 16.

4586. **An electric light switch.** Alfred Milton, Howard William Bishop, and Frederick Brown, 4, The Bridge, Walsall.

4588. **A portable electric alarm clock.** Sam Naylor, 12, Corporation-street, Halifax.

4599. **Electrolytical process and apparatus for producing bleaching powder and other materials.** Charles Lever, 77, Chancery-lane, London.

4623. **An improved metal reflector for electric search lights used in ships of war.** John Farquharson, Pomona House, King's-road, Fulham, London.

4642. **Improvements in apparatus for measuring and registering the consumption of electric energy.** Ernest Auguste George Street, 45, Southampton-buildings, London.

4654. **Improvements in meters for electricity.** Jules Cauderay, 24, Southampton-buildings, London. (Complete specification.)

4656. **Improvements in electric signal apparatus.** Henry Thomlinson, 24, Southompton-buildings, London.

4657. **Improvements in electrical weighing machines.** James Murdoch Napier, 24, Southampton-buildings, London.

SPECIFICATIONS PUBLISHED.

1881.

1240. **Armatures for electric machines.** Brewer. (Second edition. 8d.

1888.

924. **Electric measuring apparatus.** Lorrain. 1s. 6d.

4568. **Electrical conductors.** Williams. 6d.

5201. **Coin-freed apparatus for electric light.** Davies and Tourtel. 11d.

8354. **Depolarizers for batteries.** Leclanché. 6d.

NOTES.

Finance and Electric Light.—The electric light is being put into the offices of Messrs. Rothschild in New-court.

The Paris Exhibition.—The Lord Mayor's Committee have decided to send a number of electrical engineers to the Paris Exhibition.

Society of Arts.—The second Cantor lecture by Mr. C. V. Boys, F.R.S., "On Instruments for the Measurement of Radiant Heat," will be delivered on Monday, April 1, at 8 p.m.

Electric Railway with Water-Power.—The electric railway, three miles long, to be erected at Negaunee, Michigan, will be worked by water-power, 10 miles away.

Edison Patents in Canada.—With reference to the recent decision, by which Edison's patents in Canada were declared void, the Edison Company of New York state they are intending to take the case to the Canadian Court of Appeals.

The Lighting of the City.—Particulars will be found elsewhere in our columns of a meeting of the Streets Committee of the Commissioners of Sewers to receive tenders for lighting the City of London by means of electricity.

Paris.—The Municipal Council of Paris have thought it well to extend the public lighting of the streets, on the occasion of the Exhibition, along the streets on the left bank of the Seine, and have asked for a grant of 50,000f. for this supplementary lighting.

Galway.—The Galway Electric Company will use Brockie-Pell arc lamps in carrying out the contract for lighting the docks for the Harbour Commissioners. The works of the company are driven by water-power, and are in close proximity to the docks.

Arragon.—Teruel, capital of the province of Arragon, Spain, is shortly to have a central lighting station, situated about a mile from the city. The power is to be obtained by a 40 h.p. turbine, and it has been decided to adopt the alternate current system with transformers.

Electric Automatic Boxes.—A company to work an automatic electrical box is being formed in Edinburgh, to which town the inventor belongs, to supply books, and ultimately newspapers, theatrical programmes, pipes, photographs, and other similar articles of daily want.

Tramways in India.—A tramway is proposed to carry the forest produce from Courg to Hunson in Mysore, India, and the scheme is under the consideration of the Government. A proposal of this kind is one in which it would be well to press the advantages of electrical traction.

A Question of Temperature.—*Practical Electricity* asks the following question: "If, when placed in a room of 50deg. F., normal temperature, a dynamo raises the temperature to 100deg. F., what would be the increase of temperature if the normal temperature were already 100deg. F." ?

Telegrams to the Far East.—The Indo-European Telegraph Company, Limited, state that the lines being now restored, they are prepared to accept messages for transmission between this country and India, Penang, Singapore, China, Java, Australia, New Zealand, Persia, Southern Russia, and Turkey.

Electric Railway Turn-Tables.—The Philadelphia and Reading Railroad, U.S., is having a "transfer table" constructed, for which the driving plant will be supplied by the Sprague Electric Motor Company. This is the third transfer table that this company has equipped. The first was put in at Aurora for the Chicago Railway, about nine months ago, and the second will soon be in operation at the Pennsylvania shops at Altoona.

The Woolwich Free Ferry.—On Saturday afternoon, this, the first free ferry established on the River Thames, was opened to the public. Each ferry-boat is 164ft. in length by 42ft. beam, and is furnished with two independent diagonal low-pressure engines of 700 h.p.; the object being to obtain propulsion from either or both of the ends. Steam steering-gear is fitted, and 72 incandescent lamps light the saloons, etc., of each vessel.

Telegraphy and Telephony.—The remarkable manner in which telegraphy and telephony have progressed in 1888 is shown by the following figures. The number of telegraph offices throughout the world has increased in 1888 by over 7,200; the 10,000th office, says *Kuhlow's Gazette*, was opened in Germany during last year. Telephones have also undergone a similarly great extension. At present there are 750 in the United States with 200,000 subscribers. In Germany there are 174 telephones and 32,920 subscribers.

Personal.—Messrs. Mather and Platt, of Salford Iron Works, Manchester, have opened a London office at No. 16, Victoria-street, Westminster, which will be under the charge of Mr. Hardman A. Earle, who has for some years been the assistant-manager of their electrical department. Mr. A. Blackburn, Assoc.Mem.Inst.C.E., has resigned the position which he has held for some years as resident engineer to the Edison and Swan Company, and has joined the staff of Messrs. Mather and Platt's electrical department as assistant-manager.

Birmingham Exhibition.—Lithographed plans, showing the sections and available spaces at the Electrical and Industrial Exhibition at Bingley Hall, are ready to be supplied to proposing exhibitors by the Executive Committee at the County Chambers, Birmingham. As the exhibition will be the opportunity for display of the latest applications of electricity to daily life, and for actual exhibition in operation of electricity as applied to all manners and kinds of manufacturing, it will be well for electrical engineers and inventors to take early pains to render their exhibits as interesting as possible from this point of view.

Elieson Electric Company.—We have received from Messrs. Kirk, Price, and Goulty an illustrated catalogue of the articles to be sold by public auction on April 17. It is unnecessary here to enter into the history of the company, the whole of the property now coming under the hammer, as well as all the British, foreign, and colonial patents. The plant and machinery consist of a Marshall and Co.'s engine, one of their local type with tubular boilers, and a Richmond engine, a quantity of shafting, a number of dynamos, lathes, mechanics' tools, fittings and appliances for workshops, a number of motor cars and gearing, and an Elieson accumulator. The number of lots, including office fittings, is over 350.

Tenders for Zurich.—Zurich is to be lighted by electric light, by means of water power, with a plant of the capacity of 650,000 watts. The contract is open to tender from Swiss or other electrical engineers, the tenders to be

Digitized by Google

sent in before the 15th May next. The power will be supplied by the town water works, which are to be extended and supplemented with steam engines in reserve for a capacity of 750 h.p. This is equal to about 450,000 watts. When both water and steam are working together, with both arc and incandescent circuits, the capacity will correspond to the above total of 650,000 watts. Forms of tender, with plans and sections of the water power works, are to be obtained of the Bureau de la Ingenieur de la Ville, Zurich, who will furnish all other particulars.

The Proposed New Submarine Cable.—In the House of Commons, on the 21st inst., Sir E. Watkin asked the Postmaster-General whether any steps had yet been taken or decided upon in reference to laying a submarine cable between the British Atlantic fortress of Bermuda and the British fortress of Halifax; and whether it was intended to restore direct postal communication by British ships between Halifax and Bermuda; and, if not, in either or both cases, what were the reasons. In reply, Mr. Raikes stated that the Government have decided to lay a cable from Halifax to Bermuda. The Legislature of Jamaica had agreed to grant a subsidy to a line of steamers running between Halifax and Kingston, and calling regularly at Turk's Island and Bermuda. He understood that the service commenced last October.

Dover Industries.—Under the above title the *Dover Express* comments upon the work of Mr. Alfred Crofts, of Dover, who has written a *brochure* on "How to make a dynamo," and also arranged to supply amateurs with small castings, etc., for dynamo making. Our contemporary, with delightful freshness, describes a visit to Mr. Crofts' workshop. We are told how "electricity was encountered in the door-bell"; how "when a whisper of the telephone came over from America, Mr. Crofts got hold of the secret before it was practically applied in this country"; and, finally, how the dynamo is "built bone to bone and sinew to sinew." "Thus," concludes our contemporary, "Dover has been made a centre to which amateurs all over the civilised world turn for help and counsel in producing the light of modern days."

Electricity and Lifeboat Work.—Speaking at the sixty-fifth annual general meeting of the Royal National Lifeboat Institution, on Saturday last, Lord Charles Beresford said that if there was quicker communication between the stations a boat would often go out under more favourable circumstances. The question of quickness of communication round the coast deserved the attention of the whole nation, not only from the point of view of lifeboat work, but also of defence of the country. Between the lighthouses, lifeboat stations, and coastguard there should be better means of communication, and also with the head of the Intelligence Department at the Admiralty. A great many more lives would have been saved had there been electric wire communication throughout, and it was his intention to again bring the matter before the House of Commons.

A Miniature Battery.—Numerical quotations from electrical professors do not demonstrate the extreme smallness of the electric current which suffice to affect a telephone so well as an actual demonstration. Mr. J. H. Farnham, having to lecture before a New York audience, recently showed a miniature battery, to illustrate the minuteness of telephone currents. This consisted simply of a glass bead, through which was threaded a thin copper wire and a thin iron wire, the ends being connected to a telephone line. The solution was one drop of acidulated water. By means of this battery, signals were transmitted over more than 200 miles of wire. To a popular audience this is a wonderful experiment, and is, indeed, a striking illustration of the sensibility of the telephone. A drop of water containing sal ammoniac may be used instead of the acidulated water.

The Lighting at Taunton.—Since the adoption of the electric light for the main streets, Taunton has been visited by deputations from all parts of the United Kingdom. On Monday last, a sub-committee of the Bedford Town Council, appointed for the purpose of considering electric lighting, went to Taunton to see if the reported success of the electric lighting of the streets was a virtual fact. The gentlemen were conducted to the central station of the Taunton Electric Lighting Company by Mr. J. H. Smith, the surveyor, and were met at the works by Mr. O. V. Thomas, the electrician in charge. The deputation returned to Bedford on Tuesday morning with the unanimous opinion that they had never seen a better system of street illumination. On Tuesday, Taunton was again visited by a deputation appointed to obtain particulars and notice the effect of the electric street lighting. This deputation was from the Chelmsford Town Council, which is now considering the question of a better illuminant than gas for public purposes.

The Indian Telegraph Department.—In the House of Commons, on Monday last, Sir J. Gorst, in answer to Mr. D. Sullivan, said the dates for making promotions in the Telegraph Department were fixed by the Government of India, and the Secretary of State is not disposed to interfere in the matter. Mr. D. Sullivan asked the Under-Secretary for India how many officers of the Telegraph Department had more than 30 years' service; and if, in the interests of the public service, whether as regards the efficiency of the department or economy in the matter of pensions, he would consider the advisability of retiring those officers, many of whom had already been superseded by officers many years their juniors, on special pensions, rather than allow men in the prime of life, and who were specially trained for the department under the reorganisation scheme of 1886, to leave the service in disgust. Sir J. Gorst replied that the number of such officers was ten. With regard to the second enquiry, the Secretary of State saw no necessity for altering the rules as to the retirement of officers in the Telegraph Department.

The British Association.—The list of officials for the coming meeting of the British Association at Newcastle-on-Tyne has been arranged. The president will be Prof. W. H. Flower, F.R.S., Director of the Natural History Museum. The presidents of the various sections are as follows: A. Mathematical and Physical Science, Captain W. de W. Abney, R.E., C.B., F.R.S. B. Chemical Science, Sir I. Lowthian Bell, F.R.S. C. Geology, Prof. James Geikie, LL.D., F.R.S. D. Biology, Prof. J. S. Burdon Sanderson, M.A., M.D., LL.D., F.R.S. E. Geography, Colonel Sir Francis de Winton, K.C.M.G., F.R.G.S. F. Economic Science and Statistics, Prof. F. Y. Edgeworth, M.A., F.S.S. G. Mechanical Science, William Anderson, M.I.C.E. H. Anthropology, Prof. Sir W. Turner, LL.D., F.R.S. The first general meeting will be held on Wednesday, September 11, at 8 p.m. On Thursday evening, September 12, there will be a *soirée*; on Friday evening, September 13, a discourse on "The Hardening and Tempering of Steel," by Prof. Roberts-Austen, F.R.S.; on

Digitized by Google

Monday evening, September 16, another discourse; and on Tuesday evening, September 17, a *soirée*.

The Chemical Society.—The president of this society, William Crookes, F.R.S., last night delivered his inaugural address, which was on "Recent Researches on the Rare Earths as interpreted by the Spectroscope." Mr. Crookes' unique ability in this direction is known to our readers, and this address is a natural continuation of that given at the British Association. It contains nothing directly pertinent to electrical matters, though any researches which give us a fuller acquaintance with molecular physics must lead us nearer to the time and the point when we can say "this is electricity." The concluding sentences of Mr. Crookes' address may be given: If the study of the rare earths leads us to clearer views on the nature of the elements, neither my colleagues nor myself will, I am sure, regret the months spent in tedious and apparently wearisome fractionations. No one can be more conscious than myself how much ground is yet uncovered, and how many radical questions have received but very inadequate answers. But we can only work on, "unresting, unhasting," trusting that in the end our work will throw some white light upon this deeply interesting department of chemical physics.

Duties on Electric Machinery to France.—The Board of Trade have kindly communicated the following memorandum, based on the latest information in the possession of the department, for circulation to the members of the Electrical and Allied Trades Section of the London Chamber of Commerce, showing the duties levied by France on: 1. Dynamo-electric machines—(*a*) if weighing less than 30 kilos. (66lbs.), these are admitted free of duty on the same footing as "scientific instruments"; (*b*) if weighing 30 kilos., or more, they are charged with duty as "machinery unenumerated," the duties upon which category, are, containing 75 per cent. or more of cast iron per 100 kilos., 6f.; from 50 per cent. to 75 per cent., 10f.; less than 50 per cent., 15f. 2. Electric lamps—accessories of electric lighting, such as switches, regulators, arc lamps, etc., are chargeable as manufactures of metal according to class, the duty upon such as are of copper, or of copper mixed with zinc or tin, being at the rate of 20f. per 100 kilos. Incandescent lamps of blown glass are chargeable as "articles of glass not otherwise mentioned," the import duty under this head 18f. 50c. per 100 kilos. Accumulators are charged according to the metal of which they are composed.

The French Telephone Service.—Advices from Paris state that the Government has just introduced a Bill with the object of repurchasing the concession granted to the Telephone Company. Since 1879 the telephonic networks of Paris and of nine provincial towns have been worked by the company. The concession which was granted in 1879 for five years was renewed in 1884 for another period of five years, which will expire on September 8 next. The Bill proposes that the State shall purchase the company's stock of materials, and conduct the work itself. The necessary funds will be raised by the Deposit and Consignment Office. The purpose of the Government is to reduce the rates of subscription to the telephone. The second part of the scheme relates to towns which are not yet in possession of a telephonic system. The State will require towns wishing to have telephonic lines introduced to advance the funds necessary for the opening of the network, and will repay the advances by a deduction from the receipts. When the repayment has been completed, the State will take possession of the lines so constructed and work them. The town of Limoges has already entered into a contract of this kind with the State, and a Bill has been adopted confirming it. Twenty other towns having applied for similar contracts, the Government resolved to introduce the present general Bill.

The Submarine Cables.—It is stated that the price offered by the Government for the French and Belgian cables of the Submarine Telegraph Company, together with the instruments and stores, is in round figures £35,000. No offer has yet been made for the company's cable ship, buildings, and other property, the necessary valuations not having been yet completed. The cables were all valued and tested by electrical engineers appointed by the British, French, and Belgian Governments. It may be mentioned in this connection that the Belgian cables were valued proportionately higher than the French. The Post Office authorities have practically completed their arrangements for beginning the Continental work on and after the 1st of April. Officials from St. Martin's-le-Grand have been at the Submarine Company's offices almost daily. Their first care will be to overhaul the existing cables and put them in good working order. In the course of the coming summer a new cable of four wires now in the course of manufacture will be laid to France, and others will be put down as they may be required. It is also stated that on and after April 1 Liverpool will enjoy the advantages of direct telegraphic communication with the important commercial centres of Havre and Hamburg. An extraordinary meeting of the proprietors of the Submarine Telegraph Company was summoned on the 25th inst. Particulars of this meeting will be found elsewhere in our columns.

Welding by Electricity.—At the central station of the Malden Electric Company of Malden, Massachusetts, on Monday evening, the 4th instant, a successful exhibition of electric welding was given by the Thomson Electric Welding Company, of Boston and Lynn. The tests were made for the inspection of representatives of the press. Some fourteen tests in all were made, and were all successful, says the *Western Electrician*, the time for the operations ranging from a few seconds to one minute and forty seconds. Brass, copper, and iron bars of small diameter, $\frac{1}{4}$th, $\frac{5}{16}$th, $\frac{3}{8}$th, and $\frac{1}{2}$in. were first manipulated after being properly clamped. Then came the tests with larger bars; still later the joining of an extra heavy 2in. iron pipe, and, finally, round iron rods of 2in. diameter were welded. Three transformers, each of which could be put instantaneously into connection with the dynamo, were used, the selection of any individual one by the operator depending upon the size of the metal to be welded. When one of the induction-coils was in service the others were, of course, not in the circuit. After the welding of the smaller pieces of metal they were twisted until they broke, but the break in no instance occurred where the joint had been made, and what one operator had joined, others, even with the aid of mechanical devices, failed to pull apart. The tests were made by Russell Robb, under the direction of Hermann Lemp, the electrician of the company; John Tregoning, the superintendent of the factory at Lynn, was also present, as was Otis K. Stuart, who has charge of the specimen welding. No unions of dissimilar metals were made, but these can be effected easily, and the adaptability of the invention to both small and large work is particularly to be noticed. The invention is doubtless destined to be commercially successful.

The Electric Motor in Engineering.—We mentioned last week the employment of an electric motor for working a drawbridge over the river at Bridgeport, Conn., U.S. The attention of engineers of all countries who have to deal with the moving of bridges, cranes, etc., where steam is now generally used, might well be given to the extended application of the light and powerful motor to this purpose. The *Chicago Herald*, commenting upon the new application, makes the following sensible remarks: "It would be an excellent idea if the city engineer should include electricity in his calculations with reference to the turning of bridges hereafter to be built. With steam, the weight of the structure is very largely increased by the boilers and water, as well as other cumbersome appliances. There must now be a steam-engine and boiler for each bridge. In case electricity were used it could be generated at some central point and carried by wires to the various bridges. The bridges could, with only the additional weight of an electric motor, be made much lighter than they are at present. This would be a substantial economy in the cost of construction, which would lighten materially the expense of bridge building. In truth, the time is not far distant when the electric motor will be an economical substitute for the great majority of engines now operated by steam. The latter are stiff and unyielding, generating unendurable heat in summer, and must have all their parts near where the work is done. Each building using power must have its boiler and engine in the basement, and it is often the case that steampipes have to be led to other floors of the building for the conveyance of power, or else the work has to be transferred by belts, causing material loss by expensive friction. It cannot be long before electricity will supplant steam-power, as it now is doing with gas. The difference between gaslights and the electric lamp is no greater than is the width between steam and electric motors. The latter are in every respect better, and, what is more convincing than all else, they are much cheaper."

Disruptive Discharges in Lead Cables.—A paper was read recently before the Chicago Electric Light Convention by Mr. C. H. Rudd, in which he attacks the conclusions of Mr. E. G. Acheson, that failures in high-tension cables were due to the static charge. It is evident, he maintains, that we have nothing as yet to indicate that the arc makes distinction between the static charge in motion and other electricity in motion. It is also evident that the insulation of a cable does not undergo strain at shutting down due to static charge. After discussing Mr. Acheson's experiments, and giving others of his own, he says, in conclusion: "If disruptive discharges occur in properly insulated cables, we must look for the cause in those sources of high pressure which exist in nature. I do not believe that burn-outs can be ascribed to any one cause, but that each individual case has its own individual cause. In practice we must provide insulation strong enough to meet the daily strain, and suitable devices to prevent the accumulation of charge from outside sources of greater pressure than the insulation will bear. As yet we have no proof that high-pressure protectors are required anywhere outside of station from which the wires start. Mr. Acheson says that the greater number of grounds or burn-outs occurring on arc light circuits are at the terminals of the lead or at the joints, and says that such a state of things would be naturally caused by the greater density of the static charge at these points. This statement strikes me as a singular carrying over of ideas obtained in laboratory work with purely static electricity and arbitrarily applying them to entirely different conditions. The natural static charge in a cable, due to the distribution of the working E.M.F. of the current in the cable, must necessarily be governed in its distribution by the force from which it originated. The shape of the conductor cannot act in the matter of this kind of static distribution, as the shape of an insulated conductor would act upon a purely static charge. This remark of mine about distribution may not be treated of by any of the men who write books, but I confidently appeal to my hearers for support. As regards burn-outs occurring at terminals and joints, we know that great care is required to make these points equal to the rest of the cable in a matter of insulation. I do not see how it can be known that burn-outs at such places are not due to accident in construction or actual neglect on the part of the workmen."

Extension of the Richmond (U.S.) Electric Road.—The electric railway at Richmond, Virginia, writes a correspondent of the *Electrical World*, has evidently given satisfaction, for it is to be considerably extended at once. In fact, the company is now at work making the alterations necessary to change about 12 miles of road from a horse—or, to be more exact, a mule—car line to an electric road. This will just about double the present length of track. The number of electric cars will also be doubled. There are now 40 or 50 more to be added. It is thought that the changes will be completed in about a month, and then the Virginia Electric Light and Power Company, which operates the road, hopes to give the Richmondites even better satisfaction and more efficient service than it has had heretofore. It is only fair tot he company and to the cause of electric railways in general to say, however, that to the enquiries I made among those in no way connected with the electrical business, I got but one reply: "The electric road is a great success, and has given a wonderful impetus to the growth and development of the city." Everybody seems to take a laudable pride in it, and everywhere along the line of the road houses are going up, which shows how quick the citizens are to take advantage of the facilities it offers for rapid and comfortable transit between their offices and homes. Superintendent Trafford tells me that everything about the road and its electrical features runs along smoothly and pleasantly. A trip over the road, such as I made to-day in company with Mr. M. B. Leonard, cannot but convince anyone of this fact; and it is a long ride for five cents. I was much pleased with the neat, tidy, and business-like appearance of the power station, which, I ought to mention, also furnishes current for about 4,000 Westinghouse incandescent lights, as well as some 40 commercial motors—Sprague, Daft, Baxter, etc. In addition to this, the company, from another station, runs 300 Schuyler arc lights. It gets a very fair rate for the motor service—125dols. (£26) for the first horse-power and 100dols. (£20. 16s.) for each additional horse-power. The equipment of the station includes at present six No. 16 and one No. 20 Edison machines, one 2,600-light and one 650-light Westinghouse machines. The engines consist of three Armington and Sims of 125 h.p. each, two Westinghouse of 65 h.p. each, one Westinghouse compound of 250 h.p., and one Ide of 150 h.p. Another Armington and Sims engine will be put in when the changes in the road are finished, to run two more No. 20 Edison machines. An additional 2,600-light Westinghouse dynamo has also been ordered, to enable the company to meet the increasing demands upon it in this department of its business.

THE ELECTRIC SEWAGE WORKS AT CROSSNESS.

"To what base uses may we return!" is tempted to exclaim the electrical engineer when he hears of the application of the force he deals in to—not now light and beauty and swift travel—but to the treatment of sewage. Yes, and to what beneficent and healthful uses, he may well add, in consonance with the sanitary engineer, as it is proved to him that the same current that would electroplate the teapots and spoons in Sheffield alters with its magic touch the most vile and deadly matter, now poured by millions of gallons daily into our rivers, into a pure liquid—and not only into pure water, but into an absolute disinfectant. Such is, indeed, the fact; and the science of health—the coming science of the future—will have at its hand the aid of electricity to settle the enormous difficulty it has hitherto had to contend with in the disposal of the sewage of its large towns; and an engine and a dynamo will become the modern Hercules which will purge the Augean stables of our metropolis.

With this preamble upon the imaginative and prospective side of what is at best a somewhat unsavoury subject, foreign to the consideration of electricians in general, we will describe this, the most recent of the applications of electricity to the problems of civilisation, a far-reaching field of usefulness which may extend throughout the world wherever cities grow up.

The system of the electrical treatment of sewage has been explained by Mr. William Webster, the inventor, before the Sanitary Association, in 1888, when some lecture experiments were shown to illustrate the process. The paper was given at that time in the *Electrical Engineer* (see vol. II., p. 178), but the system has never been shown publicly on a practical scale until this week, on Wednesday last, when a number of gentlemen connected with the technical and daily press were invited to see the experimental works which have been constructed at Crossness. These works have been erected by Mr. Webster, under authority from the late Metropolitan Board of Works, at his own expense, to demonstrate the utility of the invention, and some 12,000 gallons of sewage per hour can be here treated, the solid matter precipitated into sludge, and the effluent water drawn off, and discharged into the river.

The Sewage and Works.

It may, perhaps, conduce to the better understanding of the process and its application if we briefly describe the present system of the disposal of the sewage of London. There are at present two main outflows—one for the districts north and the other for those south of the Thames—the first at Barking, and the latter at Crossness, 1½ miles from Abbey Wood Station. It is at this latter outflow that the experimental works of Mr. Webster have been carried out. It is a mistake to suppose that the sewage, as dealt with at these stations, is horribly repulsive and offensive to sight and smell. It is simply a dark-looking fluid, quite liquid, certainly with a scum on its surface, and a slight odour of sewer gas, but in appearance not very much worse than the ordinary streams of many manufacturing towns. This volume of impure liquid comes down a huge sewer of 11ft. 6in. diameter, and at the outflow stations is pumped direct into the River Thames without further treatment. The pumping station at Crossness is a handsome Gothic building of red and yellow bricks, with boiler-house very conveniently arranged—the coal trucks on rails, with door and platform, so that the firemen can fire direct from them. The engine-house contains several huge beam engines of the old type, now some 23 years old, but working very well, with high efficiency, and pumping an average of about 80,000,000 gallons a day, more or less, according to the rainfall over London. In some towns the rainfall is kept distinct from the sewage, but in London the rain is all drained into the sewers. The sewerage thus varies in strength, often changing from a pale amber to a dark purple in a short period. Those wishing to understand the working of the new system should note both the fact of the rainfall draining into the sewers in London and the continual change of strength.
